Thus it is that through years to come, after indeed it may be that the actual papers contributed to physiology by him may have become matter chiefly for the historian and the antiquarian, Lister will still receive unfailingly his meed of commemoration from the *physiologist and* experimentalist, and in a manner which to himself would, of all ritual and offering, have been the most congenial—*namely, in their daily observance* and trust of methods which he discovered and inculcated, and in their practice for the alleviation and prevention of disease. It is therefore with peculiar gratitude that Physiology brings its tribute of admiration and veneration to the memory of one great even among the greatest of the benefactors of humanity, Joseph Lister.

LISTER AS A PATHOLOGIST AND BACTERIOLOGIST.

BY

WILLIAM BULLOCH, M.D., F.R.S., LL.D.,

GOLDSMITHS COMPANY'S PROFESSOR OF BACTERIOLOGY, UNIVERSITY OF LONDON.

WE are met to commemorate the centenary of the birth of Lord Lister, and I have been asked to address this representative gathering on his contributions to pathological science.

Proud as I am of the great honour which has been bestowed on me, I am painfully conscious of my own imperfections and limitations for such a task. My qualifications are twofold. In the first place, I have read all Lord Lister's writings and have made a critical study of some of them, not only to discover their intrinsic merits, but to compare them with similar studies of his predecessors and contemporaries.

In the second place, I had the great privilege of knowing Lord Lister for thirteen years, and in a manner which, considering the great disparity of our positions, was, if I may presume to say so, almost intimate. As bacteriologist to the British Institute of Preventive Medicine I had to visit Lord Lister, the chairman of the Institute, almost weekly in order to report to him the progress of the work in the antitoxin department. After I left the Institute he frequently asked me to call upon him to discuss various scientific problems in which he was interested. In this way I was a good deal in his company, and among the younger men of that day I probably saw as much of him as anyone else.

When I first knew him, in 1895, he was 68, and I frequently saw him down to 1907. I last saw this great man in a bath-chair by the roadside at Walmer on a lovely sunny morning—December 26th, 1909. He was then 82 and was approaching the lonely end of his splendid career. Both then and now he stands out to me as a most impressive personality. I have known very many of

the leaders in our profession at home and abroad during the last thirty years, and have no hesitation in placing him *facile princeps Medicorum*.

Up till old age he continued to be deeply interested in all medical advances and was almost young and boyish in his enthusiasm. Although leading a busy and strenuous life, he was still striving to keep abreast of bacteriological literature, which at the time was pouring forth in an unbroken stream. On several occasions I was hours in his company trying to unravel the intricate papers of Ehrlich and Bordet on the nature of haemolysis or the constitution of diphtheria toxin. Our hour of work finished, he would relax into reminiscences of his life and work, the difficulties he had to contend with, and how he had overcome them. On one such occasion—the date was October 23rd, 1905—he referred in great detail to his work on pigmentation of the frog and on inflammation, and he said to me—I wrote the words down at the time—"If my works are read when I am gone, these will be the ones most highly thought of." These were not the mumblings of senility, for he was still alert and fresh, but I took it to mean that he wished to be regarded as a scientist rather than as a surgical craftsman, notwithstanding his pre-eminence in the latter branch of human activity.

It is therefore a peculiar pleasure to me to have to refer to some of these contributions which he himself prized.

In estimating Lord Lister's scientific work, it is essential to remember that he had no properly equipped laboratory as we understand it to-day. His laboratory was his study in his private home, and perhaps the best part of his scientific work was that done in 11, Rutland Street, Edinburgh, during his first stay (1853-60) in the northern capital. To this period belong the papers on pigmentation of the frog (1857), the function of the visceral nerves (1858), the coagulation of the blood (1858-63), and the early stages of inflammation (1857). The construction of his antiseptic system took place mainly in the Glasgow period, 1860-69, while his chief bacteriological studies are to be referred to the second stay in Edinburgh (1869-77), when he resided at 9, Charlotte Square.

The hours for his scientific work were early in the morning and far into the night, following a harassing day of active surgery in private or in hospital. He undertook his experimental work so that he might speak with first-hand knowledge of the themes he had to teach. Many of the problems, although of paramount importance practically, were obscure and complicated. Some were not capable of solution then, others have not yet been definitively settled.

Coagulation of the Blood.

The coagulation of the blood has at all times excited wonderment, and the theories to explain the process have been innumerable and are still being brought forth. In this country very notable advances were made in the eighteenth century by William Hewson, who unfortunately died before he was 35. He proved that the red blood corpuscles were bi-concave discs; he discovered the white corpuscles and performed a large number of admirable experiments to explain the process of clotting, although he never quite cleared up the mystery of its nature. His successors in the nineteenth century were not more happy. Coagulation was early studied by Lister, as it was constantly being brought to his notice in connexion with closure of the vessels, putrefaction, and secondary haemorrhage in surgical wounds. When Lister began, the prevailing theory was that of B. W. Richardson, who referred coagulation to the escape of ammonia, which was believed in some way to hold the coagulative elements normally in solution. In a long series of experiments conceived and carried out in masterly fashion, Lister showed that the ammonia theory was untenable. He clearly saw the necessity for separating the nature from the cause of coagulation, and while baffled with the former he revealed by his experiments that the latter—the cause of coagulation—is really due to the influence exerted on the blood by the contact, even momentarily, of ordinary matter of some kind. He considered that this contact brings about a reaction between the solid and fluid constituents of the blood, so that the corpuscles imparted to the liquor sanguinis the disposition to clot. As regards the cause of clotting, it cannot be said that we have materially advanced during the seventy years since the publication of Lister's work.

Early Stages of Inflammation.

Another basic pathological process which he studied was inflammation. The extraordinary changes which we call inflammation have always attracted attention, and the explanations given constitute a large part of the history of medical doctrines. When Lister began to study inflammation there was already a considerable mass of accurate knowledge on the subject. The older pathological anatomy, so ably created by Morgagni and followed up by the French school down to the time of Cruveilhier, was being replaced by the new knowledge which accrued from the discoveries of Schleiden and Schwann. At the time Edinburgh was a great centre of medical activity and a nursery of medical talent. Many of her graduates migrated across the border to attain fame in the arenas of the South. I need only mention names like Richard Bright, Hodgkin, Thomas Addison, C. J. B. Williams, Marshall Hall, and two who had a marked influence on Lister's life at University College and afterwards—I refer to William Sharpey and the exceedingly able if eccentric Wharton Jones. Their work was carried forward by Augustus V. Waller and the little known but highly successful worker William Addison. In the inflammatory process the margination of the leucocytes was taught by C. J. B. Williams and W. Addison in 1841. In 1846 Volnay Waller rediscovered the wonderful process of emigration of leucocytes, previously known to Dutrochet (1827). In a most scholarly manner Wharton Jones summed up all the knowledge on inflammation down to 1846, and himself gained the Astley Cooper prize in 1850 for his splendid essay on the pathology of inflammation.

When, therefore, Lister began to study the process he was traversing ground already trodden. He early realized, however, that much that had been done concerned the later stages of inflammation, whereas its real essence was most likely to be found by analysing the earliest changes. Examining the frog's web and the bat's wing, he took elaborate precautions that they should be in a perfectly healthy condition. By the application of irritants he passed to the study of the morbid, and investigated especially the aggregation of the red corpuscles, their increased adhesiveness, and the structure of the arterioles and capillaries. He found that the capillaries alter in size, but referred the change to something inherent in their elasticity. While admitting the existence of contractility in the capillaries, modern writers have not accepted his explanation. Lister regarded irritants as acting in a twofold manner. The primary effect was a dilatation of the vessels, brought about through the influence of the nervous system and not limited to the *locus* of the irritant. The secondary effect, on the other hand, was the direct outcome of the irritamentum itself, in consequence of which the blood becomes altered physically. The red discs become more adhesive, they accumulate in masses, and may bring about a condition of actual stasis. Strange to say, Lister made no reference to diapedesis of the leucocytes, and probably missed it altogether. The earlier discovery of Waller had left, apparently, little impress on the knowledge of the day, so that when Cohnheim described diapedesis in detail in 1867 the discovery was looked upon as something altogether new. It is to Lister's credit that he discussed inflammation from a new point of view, which Cohnheim nine years later carried to a conclusion.

Bacteriology.

When Lister embarked on his extended study on the cause of suppuration and the complications which follow surgical operations, his previous work on blood and inflammation was a great help to him. He was continually groping for the causes of the surgical disasters which were habitually happening, but light began to peer through the obscurity. This was early during his Glasgow term. In

1865 his attention was directed by a colleague to the work which had been done on fermentation and putrefaction by Pasteur from 1857 onwards. This work came upon him as a revelation, and almost at once he grasped the full significance of the Frenchman's discoveries for surgery. Ten years later he tells us specifically that the work of Pasteur "long since made me a convert to the germ theory, and it was on the basis of that theory that I founded the antiseptic treatment of wounds in surgery."

Although he frequently reiterated his indebtedness to Pasteur, it is, I think, a vulgar error to regard Lister as a mere imitator of his great French contemporary. As early as 1861, and before his acquaintance with Pasteur's papers, he was getting near the truth about suppuration, and afterwards he advanced beyond the point where Pasteur had led him. From now on he became ardent in the pursuit of bacteriology. This was about 1870, when the study of microbes had scarcely emerged as a distinct science. At the time there were two conflicting views. The one, supported particularly by the eminent botanist Ferdinand Cohn, held that bacteria exhibited a constancy in form which might be used as a basis of their classification into genera and species.

According to the other view, there is no such morphological stability, but rather a pleomorphism whereby one and the same microbe could assume different forms according to the environment. In his earliest bacteriological work in 1873 Lister ranged himself among the pleomorphists, and it has to be admitted that he suffered shipwreck when he stated that Ehrenberg's and Cohn's classification was "entirely untrustworthy." Lister's mistake was one made by a great many others at that time, and serves but to show how unwary the earlier bacteriologists were of the pitfalls lying in their path. There exists an exceedingly interesting correspondence which passed between Lister and Pasteur on the subject. Pasteur clearly saw where Lister had erred and advised him to repeat his experiments with added precautions. This, Lister did, and, profiting by his new experience, became one of the foremost bacteriological technicians and pioneers of his time. So imbued was he with lofty ideals that, instead of covering up his tracks, he handsomely admitted his error. "Next to the promulgation of truth," he said, "the best thing I can conceive that a man can do is the recantation of a published error." This sentiment was almost exactly that which was given to us sixteen hundred years ago by Celsus, who, however, added that "such a confession is suited only to a great genius whose splendour is such as to survive the sacrifice, especially in the performance of a task which is to be handed down for the benefit of posterity as a beacon of truth to warn them against similar errors." From the theory of Cohn and Pasteur it was to be presumed that in some way—at that time unknown—bacteria might be separated from each other and cultivated in a pure state. The great mycologist Brefeld early pointed out the necessity of raising pure strains or cultures from one single germ. Lister attempted this, and by unsurpassed technique, involving a remarkable understanding of the whole problem, he succeeded in obtaining a pure growth of a microbe which he called *Bacterium lactis*, and which was a cause of the so-called lactic fermentation. He grew the microbe in sterile milk and raised a pure strain, constant morphologically and physiologically, from a single bacterial cell. This was possible by the aid of an ingeniously constructed syringe of his own invention.

He also introduced several of the methods of sterilization which are in constant use to-day. His work on lactic fermentation is a classic, and stands as a model of what a scientific research should be.

Like Pasteur, Lister had the supreme faculty of seeing as if by instinct the exact experiment required to eliminate an element of doubt or to advance ahead. He was a master of the experimental method—a rare and precious gift which the Abbate Spallanzani truly said "has always been confined and always will be confined to the few."

And now I am at the end. No one could come into contact with Lister without being impressed by his noble personality, his magnanimity, his liberality, and his modesty. His aims were of the loftiest kind, and probably no medical man ever kept more steadfastly before his gaze the covenants of the Hippocratic Oath. He venerated his teachers, he taught his art to his pupils, he kept nothing secret from his profession, and followed that system which, according to his ability and judgement, he deemed best in the interest of his patients. With purity and holiness he passed his life and practised his art.

When one looks down the long vista of time and contemplates the art of medicine, three names stand prominent, and we should all feel pride in our English stock which gave birth to Harvey, to Jenner, and to the great Lister—a name to resound for ages.

LISTER AS A SURGEON.

BY

SIR BERKELEY MOYNIHAN, BT., K.C.M.G., M.S., LL.D.,

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

SELDOM is a great discovery the product of one man's mind. In the work of other men it has ancestors; forerunners possessing one or more attributes whose final and felicitous association within new work constitutes new truth. When that new truth is fully disclosed its relation to many other truths familiar to all for perhaps many years and in many associations becomes clear. The claim may then arise that those who have revealed isolated and antecedent truths have priority in the final discovery. Such truths are, however, only progenitors with no claim to be regarded as their own descendant, the new truth itself.

SURGERY A CENTURY AGO.

The immortality of Lister, whose centenary we commemorate to-day, is due to discoveries which did for the craft of surgery what John Hunter had done for its science. The oldest human remains bear evidence of surgery. Before Lister came operations had been relatively few because of their heavy mortality and their almost insupportable burden of terror and of suffering. Every operation risked the life of the patient from one single cause—putrefaction in the wound. So frequent was this that it was always expected; and whenever it appeared no man might foresee or measure its consequences. Evidence of this we find on almost every page of the old textbooks and in the biographies of the great surgeons. It is startling to read that when, in the year 1821, Astley Cooper operated upon George IV for a small sebaceous cyst on the head, so tortured was he by anxiety lest erysipelas or pyaemia might develop that he sought to put upon others the responsibility of the operation—on Cline, on Everard Hume, on anybody but himself. He speaks of the operation in terms which to us now appear absurd, fearing that "it might by possibility be followed by fatal consequences." He says, "I saw that the operation, if it were followed by erysipelas, would destroy all my happiness and blast my reputation"; and "I felt giddy at the idea of my fate hanging upon such an event"; and again, "I am certain that if anything happened to the King that at any rate I should leave London and live in retirement." It is hard to believe that a surgeon eminent enough to be chosen for service to the King should be so deeply moved at the prospect of what was to him, as to us, technically the simplest of operations. The exercise of the art of surgery brought terror then where it now brings joy, to surgeon no less than to patient.

THE FIRST STEPS.

Lister's discovery was very gradual. His earliest interests in surgical inquiry were concerned with inflammation, its cause, its nature, and possible methods of controlling it. In this, as in many of his earlier investigations, Hunter was both inspiration and guide. His paper "On the flow of the lacteal fluid in the mesentery of the mouse," published in 1857, but based on researches begun in 1853, is an extension of Hunter's experiments on absorption. His studies on coagulation of the blood began with an investigation on the blood in the veins of sheep's "trotters" obtained from the slaughterhouse. By devising neat and critical experiment he was able to carry knowledge of coagulation of the blood far beyond the point which Hunter and Hewson had attained a century before. Yet the methods he employed were clearly modifications of those used by his great forerunner. By such investigations as these Lister was training himself, but his chief interest lay always in the problem of the healing of wounds. When, therefore, he learnt of Pasteur's researches his mind was open to the new truths and expectant of them. Before the British Medical Association in Dublin in 1867 he said:

"In the course of an extended investigation into the nature of inflammation, and the healthy and morbid conditions of the blood in relation to it, I arrived several years ago at the conclusion that the essential cause of suppuration in wounds is decomposition brought about by the atmosphere upon blood or serum retained within them; and, in the case of contused wounds, upon portions of tissue destroyed by the violence of the injury. To prevent the occurrence of suppuration, with all its attendant risks, was an object manifestly desirable, but, till lately apparently unattainable, since it seemed hopeless to exclude the oxygen which was universally regarded as the agent by which the putrefaction was effected. But when it had been shown by the researches of Pasteur that the septic properties of the atmosphere depended not on oxygen or any gaseous constituent, but on minute organisms suspended in it, which owed their energy to their vitality, it occurred to me that decomposition in the injured part might be avoided without excluding the air by applying as a dressing some material capable of destroying the life of the floating particles."

Lister's first step was therefore a realization of the truth that decomposition in wounds depends upon the activity of living micro-organisms; his second, which followed immediately, was based upon the belief that such organisms might be destroyed in the wound, or as they were about to enter the wound; his third and last, which came more slowly, was founded upon the hope that the organisms within the field of operation might be destroyed before they entered the wound.

Around every step of his advance fierce controversy raged. The scepticism and hostility of early contemporaries was stupid, unimaginative, and petty. The history of science is not only the story of new truths and their slow emergence from error, it is a recital of bitter and vexatious opposition from those who should have been the first to acclaim and to welcome the new vision. Only a few weeks ago we learnt once again of the diffidence of Isaac Newton in the publication of discoveries made years before; his reluctance was due in part perhaps to a native modesty and indifference to the applause of others; in part also to shrinking of a sensitive nature from the acrimony and coarseness of controversy.

The rank hostility of Riolan to Harvey, the disdainful incredulity of Liebig at the discoveries of Pasteur, are in direct intellectual relation to the revolt of Calvin at the discoveries of Servetus, the animosities of the Church which martyred Giordano Bruno, the threat of torture which subdued the aged Galileo, and all that long record of sinister events which proclaims the inveterate hostility of impervious minds to novelty. For such minds novelty is always error, truth is bent through an angle of refraction as it enters them. Lister's answer to indifference, opposition, and denial was unfaltering continuance in inquiry and experiment, and in the demonstration day by day and case by case of changed results.

THE PAST RENEWED IN THE WAR.

Few if any now living remember the full horror of the old days. But an experience not dissimilar awaited us in the earliest days of the great war. A pestilence of infection to which we were wholly unaccustomed turned our faces towards the early struggles of Lister. On all sides we heard that our inability to check a raging suppuration in a heavily infected wound proclaimed the failure of Lister's methods. So to Lister we turned again, only to realize much more acutely how the problems which faced us had been his problems; how our experience, horrible in its new revelation, had in the first years of his practice been his daily experience. Reading Lister's works with clearer perception and new understanding of the difficulties by which he was confronted, our admiration of his patience, insight, and courage glowed into greater reverence than ever before. Lip-service we had long given to the founder of the new era; we were now compelled to realize that Lister is indeed the man who has saved more lives than all the wars of all the ages have thrown away; the man who has changed the face of surgery, the one man who has in truth created, if not a new art, at least new and safe, and illimitable opportunities for the practice of the old art.

The *first conception in Lister's mind in respect of treatment* was that the organisms within the wound, and those entering the wound, might be destroyed by some chemical agent the nature of which was to be determined by a series of experiments. From time to time changes were made as search brought to light some new chemical substance more active in destroying bacteria and less harmful to the living tissues of man. The search is not ended yet. Up to this moment it has engaged the interest of such men as Dakin, Browning, and J. B. Cohen, and no doubt it will long continue. The problem, however, is not merely that of accomplishing highest bacterial destruction with lowest cellular injury: it is rather one of augmenting the natural powers of cells and of serum to subdue and destroy bacteria and their poisons. Lister, I feel confident, realized all this to a greater degree than many of his successors. Godlee in his Life of Lister makes this quite clear. Though the earliest efforts were concerned with the abatement of existing decomposition of wound discharges, it was not long before the problem of the prevention of infection became paramount. It is beyond dispute that Lister clearly realized the distinction between the "prophylactic" and the "therapeutic" uses of chemical agents in surgery. We know now that the old quarrel as to the relative merits of the "antiseptic" and the "aseptic" methods was senseless and jejune: for Lister was indubitably the parent of both—if, indeed, there are really two methods. No surgeon ever practised with success a method in which agents for the destruction of organisms were omitted. Aseptic surgery is the wise practice of antiseptic surgery. There is a difference in detail, not in ideal or in fundamental truth.

We have no need to discuss the relative merits and claims of Pasteur and Lister. It is true that without Pasteur there would have been no Lister at the time when Lister was. Pasteur set out to discover the truth as to spontaneous generation, and by crucial and magisterial experiment settled that problem once for all. While at Lille, in the centre of a district of many distilleries, the problem of fermentation engaged his mind, and the assertion of Liebig, foremost among chemists of his day, that it was "a change in organic fluids and tissues set in motion by the access of oxygen" was shown to be incomplete. The genius of Lister lay in immediate realization of the fact that the biological truths established by Pasteur might be applied to other circumstances. His mind was prepared for the new vision by his physiological training. I make no attempt to exalt Pasteur by saying that Lister's work was corollary to his; nor to belittle Pasteur by speaking of his ignorance of the full effect of his work. Let the world be thankful for both. We who are within the profession of medicine have once again to learn that progress depends, not only upon our own efforts in the discharge of our daily task of healing, but upon an association as intimate as can possibly be with every aspect of biology.

THE ANTISEPTIC THEORY AND ITS CONSEQUENCES TO SURGERY.

The consequences of Lister's work are many and far reaching. The immediate result was, of course, the complete abolition of many of the dangers attaching to the most certain and most dreaded peril of all—infection in the wound extending to other parts, causing severe and protracted suffering, even grave risk to life itself. But when the few operations then practised became safe, it was obvious that other operations might be attempted. The result was that procedures condemned as "murderous," the practice of which should, in the opinion of high authority, lay a man open to a charge of manslaughter, were greatly increased in number as soon as it could truthfully be claimed that the risk of operation was definitely less than the risk of inaction. The most exemplary instances were found in the practice of abdominal surgery. Ovariotomy, condemned by highest authority as homicidal (the governors of King's College Hospital in 1877 had forbidden the staff to undertake it), became so safe in expert hands that neither patients nor surgeon hesitated in the choice of operation.

In all new advances in surgery it is only the patient whose disease has reached a high development threatening disability, suffering, or death who is submitted to operation; the cases with the greatest risk already attached to them are the first to undergo adventurous treatment. As the safety of surgery is shown in these, similar cases are treated, but in an earlier stage—a stage in which the surgical risks are less, the convalescence quicker, the mortality lower. Ultimately a fatality occurs only in the exceptional case, from causes connected rather with the original disease than with the operation practised. In my days as a resident in hospital ovariotomy was regarded as an operation of utmost gravity, and was performed with much ceremony in private wards and with special nurses. McGill, who led me by the hand along the path of surgery, always had a Turkish bath in the afternoon of the preceding day, and operated at an unusually early hour in the morning. Some mammoth tumours were removed—tumours which at times greatly outweighed what was left of the patient; indeed, we removed patient from tumour rather than tumour from patient. From ovariotomy an advance was made to the treatment of other pelvic conditions. Fibroid tumours of the uterus were eventrated and a constricting band of metal applied to the cervical stump, which was brought up into the wound. When for the first time I returned the pedicle to the abdomen after the operation of hysterectomy, our obstetric physician, Dr. Braithwaite, quailed with horror at such temerity. The conquest of other disease of the abdomen was soon inaugurated; the campaign owed almost everything to those who had practised what we now call gynaecology. Spencer Wells removed the enlarged spleen from a patient whose tumour he had believed to be uterine, and a condition of tuberculous ascites, miscalled "ovarian cyst," improved so much after the release of the fluid that similar cases were quickly claimed for surgical treatment.

The whole abdomen soon became the province of the surgeon, whose activities also rapidly extended to the cranial and thoracic cavities, so that at the present day neither technical difficulty nor any danger in the trauma inflicted prevents the surgeon from dealing with almost any lesion, wherever it may lie, or whatever its nature. There is scarcely any organ which cannot be attacked; there is no inherent and inescapable risk in any technical procedures.

An extension of safe operative measures within the cavities, especially within the abdomen, has resulted in a complete revision of our knowledge of the earlier structural changes in many organs attacked by disease, and of the clinical manifestations which those changes produce. Surgery has proved an implement of research; it is indeed the most powerful of all, though this fact is not yet fully realized, nor is adequate use yet made of it. In the mortuary period of pathological knowledge only the most advanced stages of disease, those stages which at last proved fatal, could as a rule be examined. The final symptoms of the terminal changes in structure were, not perhaps the only, but they were certainly the chief interest of the clinician; little was known of the dependence of earlier symptoms upon tissue changes. Pathologists and physicians alike were incredulous as to the truth or significance of much of the new knowledge which the surgeon was daily accumulating as the result of his widening observations. Even to-day the physiologist and physician do not appreciate how much is to be learnt at the bedside or in the operation theatre.

As an implement of research, surgery has been generously used by the physiologist in his experiments upon animals. Perhaps the most entrancing exploit of all was that inaugurated in this country by Ferrier and pursued by Macewen, Horsley, Sherrington, and others, by which the functions of the various parts of the nervous system have been elucidated. There is something of enthralling interest in the story of the localization of function in the cerebral cortex, in the realization that in the convolutions of the brain exist allotments each with its own highly specialized and exclusive function. The work of the surgeon upon the abdominal viscera, his discoveries concerning, not only changes of structure in various diseases, but also disorders of visceral reflexes, and symptoms associated with these, have been not less arduous, nor less interesting, and even more fruitful in the clinical study of diseases, and in the relief of human suffering.

The capacity of the surgeon to enlarge the area of his operations has been used with gratifying success in the treatment of accessible cancer. The lines of extension of this disease have been the subject of inquiry by pathological anatomists, who have studied afresh, not only the lymphatic systems of the various organs affected, but also the exact lines along which the cancer cells may drift or grow. The work of Sampson Handley on the breast, and of Ernest Miles on the rectum, are worthy of special commendation. Since we know beyond dispute that cancer is primarily a local disease, we know also that every accessible cancer is curable if operation is practised in the early stages of disease. That is not the least of the debts we owe to Lister. It is his work that has permitted us so to plan our operations that not the growth alone but also all those parts, such as lymphatic glands into which the growth makes haste to extend, can all be removed in one mass, and that infection is now the least of our anxieties.

THE FUTURE.

We may almost claim that the full effect of Lister's work is now accomplished. We know that for all time operations of every kind may be practised without the grave risks that formerly were prohibitive. The art of surgery is far in advance of all the sciences upon which its future progress depends. Until they stand abreast, or even advance ahead, the progress of surgery will be slow. The great search for us all must now be for the methods of applying new discoveries in other sciences, physiology, biochemistry, pathology, physics, and the like, to the study of disease.

Many lines close in the dial's centre. From all the vast periphery of our surgical world messages of gratitude and of homage converge upon Lister to-day. Lister made possible the new surgery, beyond all question the most beneficent art mankind has ever practised. So long as there are men to live and suffer, so long will Lister be there to heal them, to hold the gates of life ajar.

To the honoured dead we raise our monuments, some cast in bronze, some graven in stone: some, like that of immortal Hunter, begun in a man's lifetime, the work of his own hands, are enlarged and lovingly enriched through generation after generation by those who labour in the master's cause. On the roll of honour which in letters of gold bears the names of the saviours of mankind, no man is more worthy of remembrance than Lister. His living and enduring memorial is a great, and ever greater multitude of men, women, children, of every nation, of every race, of every creed, through his mercy and by the skill of his most gentle hand relieved from infirmity and suffering and sorrow, and made for a time triumphant over death itself.

It is immortal Lister we salute to-day, the supreme benefactor of mankind.

THE LISTER FRIEZE IN FAÇADE OF POLICLINICO UMBERTO, ROME.

LISTER:

A HOUSE-SURGEON'S MEMORIES.*

BY

SIR STCLAIR THOMSON, M.D., F.R.C.P.LOND., F.R.C.S.ENG.,

PAST PRESIDENT, ROYAL SOCIETY OF MEDICINE, LONDON.

"During the siege of Paris (1870-71) Nélaton, in despair at the sight of the death of almost every patient after operation, declared that he who should conquer purulent infection would deserve a statue made of gold."—LIFE OF PASTEUR.

ON April 5th, 1827—one hundred years ago to-morrow—Joseph Lister was born, the man who conquered surgical purulent infection for all humanity and for all time. There is an indifferent and somewhat neglected bust of him in Portland Place, but the statue of gold has not yet been erected, although wound infection was conquered in Lister's own lifetime.

Lister achieved more for mankind than all the surgeons from the beginning of history. Before his coming the results of surgical wounds were hardly better than in the Dark Ages, and yet he lived to see his work and teaching result in the saving of more lives than all the military heroes of all the ages had destroyed.

Fifty years ago, this year, he left Edinburgh for London. He was then 50 years of age. On the same day that he entered King's College Hospital as one of its surgeons I entered it as a student—half a century ago.

FIG. 1.—View of Glasgow Royal Infirmary from Kirk Street.

Lister was of pure English stock; his people came from Yorkshire. His father was a prosperous wine merchant in the City of London, and from him he inherited other things beside a competence. Amongst them was a taste for scientific pursuits: the wine merchant was deeply interested in the science of optics; he helped to perfect the microscope, and was a Fellow of the Royal Society. After attending private schools in Hitchin and Tottenham, Lister entered University College, London, in 1844, at the age of 17. In University College Hospital he was present at the first operation performed in this country under ether, by Liston on December 21st, 1846.

As chill penury did not repress his anxiety to see and know the best in the surgical world, he journeyed, in 1853, at the age of 26, to Edinburgh to study under Syme. This great surgeon—to whose memory and teaching Lister always remained devotedly attached—was the man of whom it was said that he never wasted a word, a drop of ink, or a drop of blood. Lister became his assistant, and, a few years later, his son-in-law.

From Edinburgh Lister, at the early age of 33, was called to fill the Chair of Surgery in the University of Glasgow (1861). There he remained until 1869, and it was chiefly during these years that he laid the foundation of antiseptic surgery.[1] In 1869, at the age of 42, he returned to Edinburgh as Professor of Surgery in the University, and there he passed the eight years of his life which he afterwards referred to as the happiest, as they certainly were the fullest and most flowing.

In 1877, exactly fifty years ago, Lister was invited to leave Edinburgh for London. Why did he come south? It was certainly not to hunt for honours and distinctions; his Quaker character thought little of such adornments. It was not due to any mercenary attraction. He was the possessor of a sufficient private fortune, and the commercial side of our profession had no attraction for him. All who knew him are convinced that he accepted the invitation to London simply because he felt that on the larger stage of the metropolis he could so demonstrate his work that he would the sooner fulfil his mission. As his biographer records, "the antiseptic doctrine had been accepted in every part of the world that counted, except London, where alone it made but little way." In taking leave of his class in Edinburgh he announced that it was only a sense of duty which impelled him to leave a school where he had received great kindness, and to take a cold plunge into what he said "might prove to be a sea of troubles."

He was indeed right; a cold and stormy sea of trouble was awaiting him in London—fifty years ago. Lister returned from his professorships in two Scottish universities to his own southern people, and to the city of his birth. Many peoples, in all times, have been addicted to stoning their prophets. England and London half a century ago were not backward in demonstrating that a prophet was not without honour except in his own country.

His first function was the introductory address of the session on Monday, October 1st, 1877. Lister, to most people's astonishment, opened his address by stating that he was going to record some experiments he had made "to obtain some positive and definite knowledge of the essential nature of a class of phenomena which interest alike the physician, the surgeon, and the accoucheur—namely, the changes in organic substance which are designated by the general term fermentation."[2] It was looked on as a bad start, and

* Read before the Royal Society of Medicine, April 4th, 1927.

altogether unsuitable, for it was generally agreed that such an abstract subject as lactic acid fermentation was no concern of a surgeon. But it was at the hospital that Lister encountered his full sea of troubles. He had stipulated that he should be allowed to bring with him from Edinburgh four assistants already trained in his methods and attached solely to his service. Of the four who accompanied Lister from Edinburgh to London one, Dr. James Altham of Penrith, is dead. Of the surviving three, one is Dr. W. H. Dobie, who has long held a high position in Chester. One is Dr. John Stewart of Halifax in Nova Scotia. He is one of the most affectionate pupils of the master, whom he has drawn in many letters and pen pictures. The fourth had been Lister's last house-surgeon in Edinburgh, and was his first in London. He is known to us all as Sir William Watson Cheyne, who succeeded his master as professor in King's College Hospital, became President of the Royal College of Surgeons of England, served his country on land in the Boer war and at sea in the great war, reached the rank of rear-admiral, sat in the House of Commons as member of Parliament, and is Lord Lieutenant of Orkney and Shetland.

The peace-loving Quaker spirit of Lister was also much distressed by the opposition he met with at the hospital from the nursing sisters of St. John. In the days of Sir William Fergusson the teaching was entirely in the wards; he passed from bed to bed, followed by a sister with a towel and basin of water, in which he dipped his hands after examining a patient. Lister upset the pious sisters by copious ablutions and by purification of many pairs of hands before a patient was touched, and many of his cases were carried or wheeled into the theatre as subjects for clinical lectures. These sisters of St. John were opposed to Lister and all his ways, and dealt him those pious and smiling stabs in which women, particularly good women, are so skilful. Lister only showed how he felt them by the little gasping sigh we all learned to know and to respect as his only sign of sorrow or annoyance.

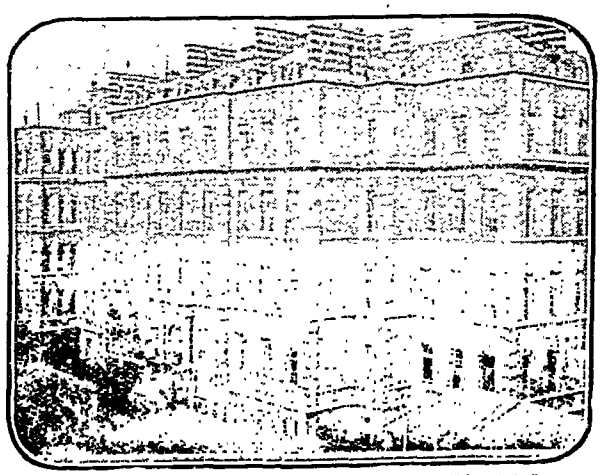

FIG. 2.—Old King's College Hospital, Portugal Street, Lincoln's Inn, London.

Worse than these two gales in his sea of trouble was what John Stewart describes as the "colossal apathy," the "monstrous inertia to the force of new ideas," the inconceivable indifference shown by the students and surgeons of London. Fifty years ago the wards of most of the hospitals in England reeked with the smell of putrefaction—just as they had done for centuries. But Lister's wards were free from what was everywhere accepted as the recognized "hospital smell"; his dressings, when taken off, were free from pus and fetor; they were handed round for confirmation, and I well remember the surprised and approving sniff with which the visitor—generally a foreigner—confirmed Lister's frequent and pleased remark: "You will notice, gentlemen, that any discharge is only serous and is quite sweet." Yet Londoners did not come to see his epoch-making change, to hear, to smell, and to be converted.

In Edinburgh Lister's class frequently numbered 400 students; in London some ten or twenty might turn up, but these gradually fell off. Ten years after his arrival Lister referred to his small classes at King's, after his crowded audiences at Edinburgh, as "a humiliating experience."

To-day, after fifty years, with new conditions and changed mentalities, it is perhaps superfluous, as well as somewhat difficult, to explain this neglect. I think the faulty method of teaching and examination had much to do with it. Lister's teaching did not help a man very much to pass an examination and secure a diploma. He was therefore neglected by the average student, while he cast a lifelong spell over those who, as dresser or house-surgeon, came under the potent power of his personality.

It is more difficult to suggest the reasons why London surgeons neglected or belittled his work. One was that Lister had, by way of experiment, to try many things in his application of Pasteur's principles to wound dressing. In these efforts he moved from carbolic lotion to boracic, or made trials of corrosive sublimate, and then reverted to carbolic. These frequent changes were all causes for stumbling to the average individual who had not grasped the first principles, and was therefore doubtful of a so-called "system" which was not definite or final. (Later in history these frequent modifications were counted to Lister for righteousness, for they demonstrated that it was the principle which mattered and not the method of technique.) Another reason was that the surgeons of the later Victorian period—just like Astley Cooper, Abernethy, and John Hunter—were without Lister's scientific training and Pasteurian knowledge, and looked upon his methods as but another variant of many previous empiric efforts. Lister himself realized this, for in one of his addresses he said: "I venture to assert that no one who has not a belief in the germ theory of putrefaction can ever perform satisfactorily the antiseptic treatment of wounds." How far the London surgeons were from being able to appreciate this is shown by an annotation in the *Lancet* in 1877 (vol. i, p. 361), which said:

> "In many quarters Mr. Lister has acquired the reputation of a thoughtful, painstaking surgeon, and has done some service to practical surgery by insisting on the importance of cleanliness in the treatment of wounds, although this has been done by the glorification of an idea which is neither original nor universally accepted."

Still, making all allowances, it is difficult to explain why London was the last place to accept the new evangel. The BRITISH MEDICAL JOURNAL, which had always supported Lister, wrote "of that great principle in surgery which had been accepted everywhere else almost before it was even listened to in London."[3]

But if students and London surgeons were apathetic over the revolution in surgery being wrought in their very midst, it was not so abroad. Already in 1875, two years before coming to London, Lister, during a prolonged tour in Germany, was received everywhere with enthusiasm. In the words of the *Lancet* (June 19th, 1875), "the progress of Professor Lister has assumed the character of a triumphal march." In 1879 Lister's appearance at the International Congress of Medicine at Amsterdam was, the BRITISH MEDICAL JOURNAL reported, greeted with "an enthusiasm which knew no bounds."[4]

At the next International Congress, in London in 1881, foreign surgeons must have marvelled among themselves when they heard British surgeons still attempting to cast doubts on the principle on which Lister founded his methods, or belittling his results. But let us, in parenthesis, project our attention forward to the following International Congress in London. It was in 1913. Lister had died the previous year, but the light of his good work was shining before all men. As is well known, congresses and such-like events are often commemorated by the issue of a medal. The medal of 1881, when Lister's work was slighted and belittled by his own countrymen, bore the features of Queen Victoria. But in 1913 it was felt in Britain that the one effigy worthy of being stamped on the medal of an International Congress in London was the head of Joseph Lister.

My audience will hardly believe me when I tell them that in my student days the surgeon of one of the largest teaching hospitals—a Fellow of the Royal Society, and a President of the Royal College of Surgeons—frequently

raised an appreciative laugh by telling anyone who came into his operating theatre to shut the door quickly, in case one of Mr. Lister's microbes should come in!

The first case in which Lister wired a fractured patella was in 1877. When I was his house-surgeon I had the honour of bringing together and exhibiting the first six of his seven first cases which he showed before the Medical Society of London on October 29th, 1883.[5] I well remember the astonishment with which Fellows of the society tried to feel the buried silver wire. Others were aghast at the unwarrantable danger incurred in opening a healthy knee-joint. One hospital surgeon, Morrant Baker, asked, "Had not ankylosis, amputation, and death been heard of after its performance?" One surgeon said that if the next case died Lister should be prosecuted for malpraxis; and another exclaimed, "C'est magnifique, mais ce n'est pas la chirurgie."

Although Lister was carrying out operations never before attempted in the history of surgery, it is interesting to record that I never saw him do an abdominal section. During my term of office we never heard the word "appendicitis"; gastric ulcers were diagnosed but never treated surgically; ovarian cysts were tapped and tapped until the patient died; that a calculus could be removed from a ureter or a bile duct never entered the imagination of anyone.

In 1897, the year of Queen Victoria's Diamond Jubilee, Lister was made a peer, his peerage having been the first ever conferred upon a surgeon. In the following May an address and dinner were offered to him by thirty old house-surgeons and one hundred dressers.

FIG. 3.—Pasteur's Jubilee, 1892. Lister greeting Pasteur at the Sorbonne.

In 1892 Pasteur's jubilee was celebrated. Lister was the predominant personality amongst all who came to honour the great French scientist. This event is recorded in a most striking picture (Fig. 3), which not only suggests the one-sided feebleness of the hemiparetic Pasteur, leaning on the arm of Carnot (the President of the Republic), but, in a marvellous manner, the artist, Rixens, gives a most lifelike representation of Lister's features, his figure, and even of his hands, gestures, and gait.

Lister had retired from the active staff of King's College Hospital in 1893 at the age of 66. He was President of the Royal Society from 1895 to 1900. In 1903, for the first time, his stalwart frame was shaken by a threatening of the infirmities of age. His last years were saddened by slowly failing health, and on February 10th, 1912, in his eighty-fifth year, he died peacefully at the little fishing village of Walmer, looking out on the English Channel.

What was the personality of this master of surgery? He was tall, upright, well knit, stoutly built, deep chested; his bearing was dignified, and his manner restrained, courteous, and considerate. His voice was low and musical, but a trifling hesitation in his speech had persisted from childhood. It was very transitory and never embarrassing. Some thought that the extra effort and emphasis required in overcoming this occasional stammer added a little charm to his speech, but he himself was very conscious of it, and referred to it as "a severe thorn in the flesh."

His manner had a certain aloofness about it. His lifelong disciple, Watson Cheyne, confesses that Lister always inspired him with a certain sense of awe. I myself felt that his soul was "like a star and dwelt apart." I can only say that no teacher, no friend, no man I have ever known has left his impress on me as Lister has done. To none of them do I feel the debt I owe to him, for the example of his veracity of thought and word, his patience and constancy in the pursuit of truth, his eagerness to instruct his pupils, his long-suffering with stupidity, his tenderness to the poor, and his gentleness to the sick and maimed.

He was imbued, I need hardly say, with a truly scientific spirit. His studies in physiology and pathology, and their bearing on clinical surgery, will be referred to in addresses by experts during this centennial week. He urged the necessity of experimental and laboratory research. In 1875 Queen Victoria, to whom only one side of the question had been presented, wrote requesting him to take action for the suppression of vivisection. Although he held a court appointment he had the courage to decline an invitation he could not conscientiously accept. He wrote to her private secretary as follows: "I should deeply regret that I cannot see my way to comply with this request, were I not persuaded that my doing so would not promote the real good of the community, which I know to be Her Majesty's only object in the matter."

In the same way, although he used the cases in his service very freely for class demonstration, his patients never resented it—were even proud of it. One of his sayings was, "The individual patient asks to be relieved and not to be studied." This reminds us of the great saying of a Frenchman, "L'amour de la médecine fait le savant, l'amour du malade fait le médecin."

He felt checks and disasters very keenly, but a certain buoyancy soon restored his equanimity and forward-looking temperament. He himself writes thus when on a holiday: "I have the happy faculty of being able to throw off all thoughts of work for the time being." He fished, but, as his biographer remarks, he was a diligent amateur but never an expert. He skated, and could do 8's and 3's—but of small dimensions! He took a fair share of vacation, and on his holidays could be light-hearted and boyish. But complete idleness was not congenial to him; on his holidays there were usually proofs to correct, or addresses to prepare. On the Continent he practised and improved his very good French and German, and in both of these languages I have often heard him speak fluently, easily, and without preparation. He was devoted to walking and excursions. He was interested in botany and bird life; and he could always fall back on a pocket edition of Horace, Dante, or Goethe.

Lister's hand was large and neither graceful nor delicate-looking. He was a steady, firm, and deliberate operator.

It is interesting to visit the surgical block of the great hospital in Rome, the Policlinico Umberto I. The bas-relief in the tympanum over the main entrance shows Lister operating, and wearing a white gown. Now, Lister never wore a white gown, nor a mask, nor gloves. He frequently never removed his coat, but simply rolled his sleeves back, and turned his coat collar up, so that his white starched collar would not be made sodden by the cloud of carbolic spray in which we operated. Sometimes he removed his black frock-coat, and an ordinary towel was pinned across his chest. I myself, for operations, put on an old blue frock-coat which I had worn for years previously in the dissecting room. It was stiff and glazed with dry blood. Yet our cases, as I remember them, healed as rapidly and as smoothly as they do with all the ceremonial and ritual of sterilization and asepsis nowadays.

Lister, this genius, created anew the ancient art of healing. He did more for surgery and mankind in

his lifetime than all the surgeons of all the ages had effected since the days of Hippocrates. I venture to say that, as an instrument in God's hands, Lister has wrought more for the relief of bodily suffering, for the security of life, for the prevention of anxiety, for the conversion of sorrow into joy, for the promotion of happiness, and for the enrichment of the life of mankind than any one man who has ever trod this earth. The history of our world is divided into the two periods, before and since the coming of Christ—B.C. and A.D. The history of medicine and surgery, and of human bodily suffering, will always be divided into the times before and after Lister. He was our countryman, and the greatest of the masters of surgery; we have lived through the golden age when he evolved this miracle of healing which had waited for centuries for his coming, and now can be wrought by every surgeon in every country in the world. Any house-surgeon, any newly qualified doctor, can to-day remove pain, arrest disease, and save life by perfectly safe operations which no man knew of, or, knowing, dare not adventure when Lister came to London fifty years ago.

Those who chanced to come near this great master caught glimpses of such a spirit as is seldom revealed to us. We are fortunate in possessing a perfect portrait of him in an imperishable poem, written by W. E. Henley, who at one time was his patient in the Edinburgh Infirmary:

> "His brow spreads large and placid, and his eye
> Is deep and bright, with steady looks that still
> Soft hues of tranquil thought his face fulfil—
> His face at once benign and proud and shy.
> If envy scout, if ignorance deny
> His faultless patience, his unyielding will,
> Beautiful gentleness and splendid skill,
> Innumerable gratitudes reply.
> His wise, rare smile is sweet with certainties,
> And seems in all his patients to compel
> Such love and faith as failure cannot quell."

Lister was born a Quaker, but he lived most of his life and died a member of the Church of England. He was blessed with a loving and devoted wife, who appeared to have no thought or interest beyond her husband. They were inseparable companions in all his work and in the numerous Continental trips he loved to make. It was while on one of these, in Italy, that his wife died, after a brief illness, in 1893. They had no children, and after his wife's illness Lister was a lonely man. He lies buried beside her in West Hampstead Cemetery.

As illustration of his noble spirit I will give a few sentences from two of his addresses. As a young professor of 33 he told the Glasgow students in his inaugural lecture in 1860 that the two great requisites for the medical profession were—"first, a warm loving heart; and secondly, truth in an earnest spirit." Eighteen years later, in a graduation address to newly qualified students, he said: "If we had nothing but pecuniary rewards and worldly honours to look to, our profession would not be one to be desired. But in its practice you will find it to be attended with peculiar privileges, second to none in intense interest and pure pleasure. It is our proud office to tend the fleshly tabernacle of the immortal spirit, and our path, if rightly followed, will be guided by unfettered truth and love unfeigned. In the pursuit of this noble and holy calling I wish you all God-speed."

In the north transept of Westminster Abbey there is a marble medallion of Lister's bust, placed near to those of the great scientists Darwin, Stokes, Anderson, and Watt. At the public funeral service in the Abbey on February 16th, 1912, there was sung an anthem of Handel's to words so peculiarly applicable to our dear master that I cannot better conclude than by quoting them:

"When the ear heard him, then it blessed him, and when the eye saw him, it gave witness of him; he delivered the poor that cried, the fatherless, and him that had none to help him. Kindness, meekness, and comfort were on his tongue. If there was any virtue and if there was any praise, he thought on those things. His body is buried in peace, but his name liveth for evermore."

A CASE OF EXCISION OF KNEE AND ELBOW JOINTS BY LORD LISTER:

CONDITION FORTY YEARS AFTER.

BY

SIR GEORGE THOMAS BEATSON, K.C.B.,
M.D.ED., B.A.CANTAB.,
SURGEON TO GLASGOW ROYAL CANCER HOSPITAL.

(*With Special Plate.*)

IN view of the approaching Lister Centenary, I thought that the following case would be of interest. It is that of Arthur Howard, aged 67 (?), cattle driver, who was admitted under my care to the Glasgow Royal Cancer Hospital on April 3rd, 1925, suffering from an inoperable malignant growth of the right orbit. The case was apparently not suitable for radiation treatment either by deep therapy or by radium. The history of the growth Howard gave was that nine years previously he had an ulcer on his right upper eyelid which was excised, but recurred some months later. Three years before admission he had an application of carbon dioxide snow, when being treated in a Glasgow hospital, and he also attended the Glasgow Royal Infirmary once weekly for seventeen months for electrical treatment. The growth, however, continued to enlarge, and he was sent to the Glasgow Royal Cancer Hospital. It is unnecessary to give a description of the case on admission, beyond saying that the mass completely overlaid the right eye, which was entirely hidden, and extended over the bridge of the nose. The tumour bled easily; but there was no glandular involvement. On questioning Howard as to past illnesses, he stated that forty years before (1884) he had had his left knee-joint excised in King's College Hospital by Lord Lister for tuberculosis, as also his left elbow-joint. In addition, the middle fingers of both hands were removed at the metacarpo-phalangeal joints. The knee-joint was excised about three months after the elbow-joint, and the right middle finger was removed at the same time. The left middle finger was amputated when the elbow was excised. (Fig. 1.)

On examination, the left knee-joint was found to be completely ankylosed, there being about two inches of shortening of the left leg. (Fig. 2.) The excision was apparently performed through a semilunar incision. The left leg is in a position of complete extension, and gives the patient perfect support. The patient had good free movement of the left excised elbow-joint. There was a certain degree of lateral and antero-posterior instability, but in spite of this the joint could be actively extended and flexed. (Fig. 3.) The patient could also pronate and supinate the forearm, these latter movements being best performed when the joint was slightly flexed. There were evidently several osteophytic outgrowths present in the neighbourhood of the new joint. The left and right middle fingers had been disarticulated at the metacarpo-phalangeal joints. The affected arm was nearly three inches shorter than the right one.

Skiagrams were taken of the elbow and the knee. Those of the elbow-joint (Figs. 4 and 5) show that the lower extremity of the humerus and the head of the radius have been removed, but the olecranon process of the ulna appears to be intact. The upper extremities of the forearm bones articulate with the anterior of the humerus about one inch above its lower end, the latter thus projecting beyond the joint. The skiagram (Fig. 6) of the left knee-joint shows that the patella, lower end of femur, and upper end of tibia have been removed, and the femur and tibia united by wiring. The line of union between the femur and tibia can be recognized, except over an area of about one inch. On the inner aspect of the upper extremity of the tibia the skiagram reveals a dense opacity, showing no definite structure. This dense shadow is almost completely surrounded by an area of bone, which exhibits marked rarefaction. This shadow probably represents a sequestrum. The skiagram also shows the wire suture in position.

This case has an historic interest, showing us after a lapse of many years the work of Lister as a surgeon; but it has a further interest in revealing the presence of the wire

SIR G. T. BEATSON: EXCISION OF KNEE AND ELBOW JOINTS BY LORD LISTER.

FIG. 1.—Antero-posterior view of injury, showing displacement of the medial malleolus and fracture of the fibula.

FIG. 2.—Lateral view, showing an anterior dislocation and forward displacement of the medial malleolus.

FIG. 3.—Antero-posterior view the day after the fracture-dislocation had been fixed in a three-piece sectional plaster casing; the alignment was considered satisfactory.

FIG. 4.—Lateral view (taken at the same time as Fig. 3), showing the anterior dislocation and forward displacement of the medial malleolus corrected.

FIG. 5.—Taken eight weeks after injury. Shows the position to be similar to that in Fig. 3.

FIG. 6.—Taken at the same time as Fig. 5. Shows the position to be similar to that in Fig. 4.

suture. When I was house-surgeon with Lord Lister in 1873 he had then begun to extend the scope of his operations, having full confidence in his antiseptic system. The two great objects Lister had in view when he came to Edinburgh in 1869 were, first, the importance of perfecting his technique in the matter of dressings so as to make them reliable for excluding the micro-organisms from the wound during its healing; secondly, he was desirous to increase the scope of his operations so as to furnish further evidence of the reliability of his antiseptic system of surgery. The cases he selected to extend his operative measures were the remedying of bone deformities and the wiring of ununited and badly united fractures. At that time he used silver wire, but was unwilling to leave the wire *in situ* after union had taken place, and it was nearly always removed, as, apparently, he regarded it as a foreign body that might be an irritant and the cause of future trouble. The case reported to-day shows that he had evidently departed from that view, and had had no hesitation in leaving the wire *in situ*. It is interesting to note that he had left intact the olecranon process of the ulna, and I learn from Dr. Stewart of Halifax, N.S., who was then working with him in London, that when that process of bone was not diseased Lister was in the habit of leaving it. It is interesting, too, to note that the articulation of the upper extremity of the forearm bones with the anterior of the humerus about one inch above its lower end allowed the projection of the latter considerably beyond the joint, there being no surface of bone against which it worked, and which would have ensured its attrition.

A HINGED GRAFT FOR UNSTABLE FEET.*

BY

ARNOLD K. HENRY, M.B., B.Ch., F.R.C.S.I.,

PROFESSOR OF CLINICAL SURGERY, ROYAL SCHOOL OF MEDICINE, CAIRO; DIRECTOR OF THE SURGICAL UNIT, KASR EL AINI HOSPITAL.

(*With Special Plate.*)

In February, 1926, Rutherford Morison and W. Mackenzie published a method of treating cases of paralytic foot-drop in children.[1] In children, as in animals, it is notoriously difficult to secure ankylosis by operating on unstable joints without injuring the growing ends of bone. Morison and Mackenzie solved the problem for the ankle by taking osteo-periosteal strips from the tibia and implanting them into beds cut in the bones of the leg and tarsus. The grafts became "osseous ligaments" which completely fixed the joint.

This method of osteo-periosteal grafting is capable of wide application, and takes rank, I believe, with the notable contributions to orthopaedic surgery of the past twenty years. But while these grafts give the best available way of procuring absolute fixation in children with foot-drop, there are many unstable feet in which some movement may with advantage be preserved. Apart from those limbs in which enough contractile force remains to permit of tendon transplantation, there are others with muscles either unsuitably placed or too weak to be used with effect.

Talipes Calcaneo-Valgus.

The deformity of talipes calcaneo-valgus is a case in point, and many imperfect remedies have been proposed for its correction. Transplantation of the peronei is inadequate whether (*a*) their tendons are fixed directly to the inner border of the foot, or (*b*) are used to replace the long extensors of the toes, while these in turn are shifted to a medial insertion.

Tendon fixation is often followed by stretching, and astragalectomy—in young children at least—frequently results in an inward rotation of the front of the foot. At best, too, astragalectomy gives a squat, unshapely ankle. The need, then, in this deformity is for the strongest possible support compatible with useful movement, and this may be obtained by fixing the unstable articulation in bony splints provided with a false joint or hinge.

The Hinged Graft.

My first experience with osteo-periosteal grafting showed me that the method held an unexpected resource. Morison and Mackenzie, intent upon absolute immobility, fixed their cases of "dangle foot" firmly in plaster immediately after operation; the first dressing was done a month later, and the foot was at once put back into plaster for a further six weeks.

In my patient, whose peroneal nerve had been divided at another hospital in the treatment of a tuberculous fibula, there was a healing tuberculous ulcer on the dorsum of the foot which made enclosure in plaster undesirable. After grafting, therefore, his leg was put on a back-splint with the footpiece set at a right angle. In spite of the unpromising skin condition the wound healed by first intention, but bandages, of course, could not give the rigid fixation of plaster-of-Paris. Small movements must have occurred, for after thirty-eight days a few degrees of mobility were present in the ankle. Radiograms showed that the grafts had fused respectively with the bones of the leg and tarsus, but where they crossed the ankle there was in each a small hinge. An opportunity soon occurred for utilizing this chance discovery.

A child, aged 7, who had had untreated infantile palsy for three years, was brought to me with a very marked calcaneo-valgus deformity. The right foot could be dorsiflexed till the instep touched the leg; the outward displacement, too, was extreme. Postural treatment in over-correction did not diminish

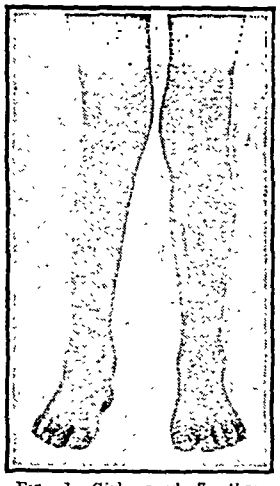

FIG. 1.—Girl, aged 7, three months after treatment of extreme calcaneo-valgus deformity of the right foot by hinged grafts.

FIG. 2.—Same patient as Fig. 1, seven months after grafting, standing on grafted foot.

the deformity, and I determined to try the effect of osteo-periosteal grafts. I employed the following procedure.

After the usual "double" preparation of the skin on two nights preceding operation, an incision was made which curved on to the tarsus behind each malleolus. The knife used for incising the skin was discarded and the skin edges were excluded from the wound by side curtains. (I find in orthopaedic operations which require neighbouring incisions that side curtains are best fixed to the lips of the wound by Michel clips, which occupy less space than towel forceps.)

On the medial side the tendons of the tibialis posterior and the flexor longus digitorum were dislodged from behind the malleolus and raised from the tarsus. On the lateral side the peronei were similarly dealt with. Grooves were then gouged in the beds of these tendons. An incision over the tibia (*Fig.* 1) allowed two grafts to be outlined with a knife on its subcutaneous surface; these were cut with a chisel from the tibia in the form of pliable strips of periosteum encrusted with bone, and were laid with their bony face on the gouged grooves. The displaced tendons were sutured back into position over the grafts and thus held them in place. Neither the grafts nor any part of the wounds were touched except with instruments. Unchromicized (and untouched) catgut was used for suturing, and the knots were tied with forceps. The skin was closed with Michel clips only, exact coaptation being secured by the transverse needle scratches which preceded the incisions.

* A paper read before the Egyptian Branch of the British Medical Association, January, 1927.

After-Treatment.

The limb was bandaged to a long back-splint, with the foot at a right angle to the leg, for one month. At the end of this time there was, as in my first case, a small degree of movement at the ankle-joint. The foot and leg were put into plaster for another month, and the child was allowed to stand on the plaster casing.

Three months after operation radiograms showed the grafts as well defined bony structures on either side of the ankle, with a distinct hinge at the level of the joint. The gait at this time was greatly improved though still rather clumsy.

Six months after operation the child returned for examination, when the photographs and radiograms shown in Figs. 1 to 4 were taken. She could then stand firmly and without deviation

FIG. 5.—Girl, aged 15, before operation, with left calcaneo-valgus deformity and right pes equino-varus (both paralytic).

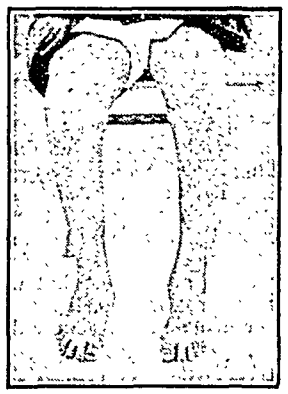

FIG. 6.—Same patient as Fig. 5, nine weeks after hinge-grafting to correct the calcaneo-valgus of the left foot. (The equino-varus deformity of the right foot was treated by tendon transplantation seven weeks previous to the photograph by the method described by Dr. Handousa. (See p. 666.)

on the grafted foot while the other was raised (Fig. 2). Dorsiflexion of the ankle was present to the extent of 35 degrees, and there were 13 degrees of plantar flexion. The gait would have been normal but for a slight rotation inward of the untreated left leg.

I have since repeated this procedure in a girl of 15 with a paralytic calcaneo-valgus deformity in the left foot.

The right foot was fixed by contracture in the exactly opposite position—that is, in equino-varus (Fig. 5).

I first operated on the calcaneo-valgus deformity, using two osteo-periosteal grafts in the way I have described. I then over-corrected the opposite deformity in the right foot by manipulation and afterwards transplanted the tibialis anterior and extensor hallucis longus to the outer side of the foot, using a technique for joining and fixing the tendons recently suggested by Dr. Ahmed Handousa, surgical registrar at Kasr el Aini, in the Surgical Unit, whose method is described, with figures, at page 666.

I mention the second intervention because of necessity it prevented weight-bearing on the grafted foot, and so caused such rarefaction of the grafts that at the risk of disturbing the transplanted tendons I made the patient stand for short periods on the plaster casing. After three weeks recalcification of the grafts was well marked, and her left foot was stabilized with a range of about 20 degrees of vertical movement at the ankle.

The strengthening of these grafts with use, shown in the figures of Morison and Mackenzie, who have observed some of their cases for five years, is in contrast to the weakening and stretching which are the end of so many alluring orthopaedic methods.

The hinged osteo-periosteal graft thus has the following advantages in the treatment of talipes calcaneo-valgus:

1. It promises a stability which depends upon function.
2. It requires a much shorter and less complex after-treatment than do tenoplastic methods.
3. It allows useful movements to persist.
4. It does not disfigure the ankle (see Figs. 1, 2, and 6).

Apart from their own peculiar value in calcaneo-valgus deformity, I would suggest that it may be possible by the aid of these grafts to extend the scope of tendon transplantation. The most fruitful cause of failure after this operation comes of stressing the tendons too much or too soon, and I believe that once hinge grafts have splinted a foot so as to prevent lateral or medial deviation the residual muscular force may be exploited with the greatest economy and effect. Thus a peroneal muscle which is too weak to procure both inversion and dorsiflexion (say in a case of equino-valgus) by suitable insertion may be made the dorsiflexor of a foot where deviation is prevented by hinged bony splints. We hope to investigate this suggestion more fully in the Surgical Unit at Kasr el Aini Hospital.

I am indebted to Dr. R. A. Gardner for the radiograms which illustrate this paper.

Summary.

A method is described of splinting an unstable foot by means of hinged osteo-periosteal grafts which allow a useful degree of mobility. The hinge is procured by conniving, during after-treatment, at slight movements.

THE TREATMENT OF FRACTURE-DISLOCATION OF THE ANKLE-JOINT BY THE THREE-PIECE SECTIONAL PLASTER.

BY

R. WOOD POWER, M.B., B.Ch., F.R.C.S.I.,

SURGEON AND ORTHOPAEDIC SURGEON, HEREFORDSHIRE GENERAL HOSPITAL.

(*With Special Plate.*)

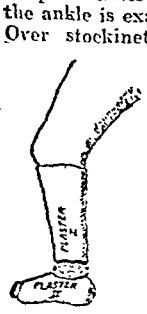
THE treatment of fractures has in many cases become standardized and the results so perfect, when the treatment is efficiently carried out, that normal anatomical union and full function can almost be guaranteed. Fractures of the clavicle treated by Sayre's method, of the shaft of the humerus in Jones's humerus extension splint, those of the elbow in full flexion (with the exception of fractures of the olecranon), fractures of the shaft of the femur by extension, and of the neck of the femur by extension and full abduction in a long spica plaster, are fractures which are treated by a universal method, and, generally speaking, the results are good. There remain others which are treated by various methods, and it is little wonder that the results are not uniformly successful. Fracture-dislocation of the ankle-joint is one which comes in this category, as proved by the numerous splints that have been used in its treatment. The box splint, the blanket splint with two lateral wooden splints, the pillow splint, also with two lateral wooden supports, a posterior moulded plaster splint, Volkmann's trough splint, Dupuytren's, and Syme's horseshoe splint are some of the more popularly used, and are recommended in modern textbooks and writings.

To procure a freely movable ankle-joint with the patient walking without pain after a fracture-dislocation of the ankle is indeed a great accomplishment, but in what percentage of such patients can we claim this? Writing on Pott's fracture Sir Robert Jones[1] states, "Pott's fracture has been generally looked upon as a most disabling accident, and many surgeons of experience complain that perfect function is rarely restored to the ankle." And again, to quote Sir William Wheeler,[2] " . . . yet the treatment and the results are far from being universally satisfactory. It is the old story: Want of proper reduction at the time of the injury and want of precautionary measures to prevent displacement when weight-bearing is permitted." The difficulties appear to be threefold: first, in obtaining accurate reduction; secondly, in maintaining the position over a period of several weeks; and thirdly, in the after-treatment.

Accurate reduction is usually a simple matter, provided a general anaesthetic is administered; the main difficulty arises in maintaining the corrected position. I think it is the experience of most surgeons that the treatment of

these fractures by splints is a most unsatisfactory procedure, and I agree with Cochrane[1] when he writes:

"The ordinary means of splintage, as in the use of the box splint or in the special splints which have been devised from time to time, are too haphazard in this respect; while one of these means is being employed, the fracture redisplaces, or does so subsequent to the patient's return to bed. All the work of reduction and the risk of the anaesthetic go for nothing, and the patient is in the unfortunate position of having to subject himself to another attempt at reduction, with the certainty of the same thing happening again."



Hey Groves,[4] after discussing the treatment of these fractures by various splints, comes to this conclusion: "But if the plaster is applied only after full correction of the deformity and with due regard to the position of the foot, and is removed for massage and movements from the first, nothing can be better." Cotton,[5] writing on these fractures, states: "If the lesion is promptly recognized, there is no difficulty in holding it. I have found it necessary to use plaster-of-Paris from the first, and have employed a position of maximum dorsal-flexion to prevent redisplacement." And again, Roberts and Kelly[6] write: "If anatomical apposition of fragments is known to be present, the foot and leg are placed in a gypsum case, extending from the toes to just below the knee." Finally, Page and Bristow[7] condemn splints in the treatment of such fractures, and state, "Fixation is best secured by means of plaster-of-Paris." I would venture to say that fixation in plaster is the only certain method of maintaining the corrected position of fracture-dislocation of the ankle.

The answer to the question why all fracture-dislocations of the ankle are not treated in plaster casings is twofold: first, the erroneous feeling of the "unknown" beneath a plaster when *x* rays are not easily accessible; and secondly, the results have not been sufficiently good to justify it becoming a standardized form of treatment. The difficulty arises in *maintaining the corrected position* during the application of the plaster, for with the slightest alteration of position or movement of the hands the dislocation recurs. This is practically unavoidable in the application of a one-piece plaster; momentary slackening of the hands must occur to make way for the turns of the plaster bandage around the foot, and it is at this moment that the dislocation recurs. This range of movement is generally so slight that it is impossible to detect it until the ankle is *x*-rayed, and we find our labours all in vain. Cochrane showed us the way out of this difficulty when he advocated the three-piece plaster of Fiske in the treatment of these cases.

This method was originally advocated by Fiske in the *treatment of congenital club-foot*, and Cochrane has successfully applied it to the treatment of fracture-dislocations of the ankle. Since then Wheeler and others have advocated it with equal success in the treatment of fractures of the lower third of the leg. I have treated twenty cases by this method, and have found the results exceedingly satisfactory; in no case has the dislocation recurred during the application of the plaster.

The Method.

Full muscular relaxation is essential, either by general or spinal anaesthesia. After a preliminary *x*-ray inspection the ankle is examined and the fracture-dislocation reduced. Over stockinette and a single layer of wool-wadding, *plaster 1* is applied, extending from just below the knee to about one inch above the ankle-joint. Here I depart from the customary procedure of bringing the plaster above the knee. Provided the wool is *not* too thick and the plaster is well moulded below the knee, I have not found this detrimental to the ultimate result; on the contrary, it facilitates the movement of the patient during his convalescence, and he maintains a freely movable joint all through. Plaster 2 is next applied to the foot, extending from the toes to about one and a half inches from the lower end of plaster 1. It is advisable to mould this plaster well around the heel, otherwise it is apt to slip off the foot during the final adjustments. If the assistant holds the foot in as near the corrected position as possible during the application of plaster 2, the risk of pressure sores will be greatly reduced. This is specially liable to occur on the dorsum of the foot at the upper end of plaster 2 when the foot is finally dorsiflexed. The plaster should be trimmed at this point and the wool turned back over it before applying plaster 3.

When plasters 1 and 2 have dried the operator takes the *foot and makes the final adjustments*. In doing so he must direct his attention to three cardinal points: first, the complete correction of the dislocation; secondly, the accurate apposition of the medial malleolus; and thirdly, the accurate apposition of the torn deltoid ligament. To fulfil the first the ankle is dorsiflexed to its full degree. In order to accomplish this the knee must be flexed to slacken the tendo Achillis and counter-pressure applied to the leg while the operator lifts the ankle well forward. The *medial malleolus will come very nearly into line during* this manipulation, and a little moulding will *get it into* perfect position. The foot is finally inverted to secure apposition of the deltoid ligament. While the operator holds the foot in this position the assistant applies plaster 3. The ankle is *x*-rayed the following day in both planes, and *if the position is satisfactory* and no swelling or discoloration of the toes be present the patient is sent home on the *third day* and encouraged to get about on crutches. Like most fractures, once perfect apposition is secured the patient complains of little pain.

After-Treatment.

The plaster should remain in place for two or three weeks; at the end of this time it is bivalved and the anterior half discarded. Massage and movement are then commenced and carried out daily. The posterior plaster splint should be retained for a further period of four weeks; it fits the foot and leg like a glove, and no substitute in the way of a splint will ever take its place, for while it is worn we are assured that displacement cannot occur. Six weeks after the injury the posterior half may be discarded, but weight-bearing is not permitted for a further two or three weeks. When this is commenced the inner side of the boot is raised half an inch by the usual method; this boot is worn for at least six months. In heavy subjects it is advisable to support the ankle with an outside iron and inside T-strap over the same period.

Report of a Case.

A man, aged 57, slipped off a haystack, falling about eight feet and landing on his left foot. The foot gave way beneath him and he was unable to rise from the ground. The ankle was found to be greatly deformed, the foot was markedly inverted, swollen, and dislocated laterally.

The man was removed to hospital and *x*-rayed. The skiagram (antero-posterior view) showed marked displacement of the medial malleolus with the usual fracture of the fibula (Fig. 1). The lateral view showed an anterior dislocation and forward displacement of the medial malleolus (Fig. 2).

A general anaesthetic was administered within an hour and a half of admission to hospital, and the fracture-dislocation put up in a three-piece sectional plaster casing.

Radiographs taken the next day showed the bone alignment to be satisfactory (Fig. 3), and that the anterior dislocation and displacement of the medial malleolus had been corrected (Fig. 4). The following day the patient was discharged to his home on crutches. He was radiographed eight weeks later and the positions were found not to have altered in either case (see Figs. 5 and 6).

The patient did not bear weight until ten weeks had *elapsed*, by which time he had a freely movable ankle-joint. Seen three months later he was walking normally and without pain.

Conclusions.

1. Plaster fixation is the only certain and satisfactory *method of maintaining the corrected position of fracture-dislocation* of the ankle.

2. The three-piece sectional plaster casing assures the maintenance of the corrected position during the application of the plaster, which a one-piece plaster *fails to do*.

3. The patient can be discharged from hospital on the third day on crutches with the assurance that the position cannot alter during his absence.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

EGYPTIAN BRANCH.

A CLINICAL meeting of the Egyptian Branch of the British Medical Association was held in Cairo on January 16th in the Physiological Department of the Royal School of Medicine, Kasr el Aini, with Dr. R. J. COLEMAN in the chair.

Cases and Radiograms.

Professor A. BIGGAM showed typical cases of Egyptian splenomegaly, pellagra, and ankylostomiasis. He also showed a case of congenital heart disease with normal temperature, no clinical signs of lung involvement, and sputum negative to tubercle, in which *x* rays indicated diffuse tuberculous pulmonary disease. A case of aneurysm of the aortic arch was also shown. The heart was markedly displaced downwards, and to the right of the sternum was an expansile pulsating swelling the size of a hen's egg, which had eaten its way through the fourth costal cartilage. *X* rays showed this to be a sacculation from a large clotted aneurysm of the arch. The patient had experienced no pain or discomfort at any time, and only came to hospital because he noticed this local swelling.

Dr. R. A. GARDNER showed a series of slides made from skiagrams taken in the radiological department of Kasr el Aini Hospital. They included a case of ventriculography, where the method had been successful in correcting a clinical diagnosis of frontal tumour by demonstrating an infratentorial lesion. Skiagrams from a patient showing Madelung's deformity of the wrist (unilateral) also showed an arrest of development of the fourth metatarsal, but no definite sign of rickets was found in the usual sites. Slides were also shown of a large aortic aneurysm projecting through the anterior chest wall without symptoms other than those due to the external local swelling. Pyelograms were shown of a case where, in addition to the usual appearances, an irregular shadow in the iliac region communicated by a narrow short connexion with the normal ureter and suggested an accessory kidney and ureter. A striking case shown was that of a boy suffering from congenital heart disease who had not, nor so far as could be found had ever had, any symptoms of pulmonary disease, yet whose lung skiagram gave a picture indistinguishable from that seen in miliary tubercle. Slides from several other cases were shown, including a normal cholecystogram, a fracture of the spine demonstrated with lipiodol, a case showing multiple bone metastases, and a large calcified renal tumour.

Dr. SHAHEEN BEY showed specimens of foreign bodies removed from the oesophagus.

The following cases from the surgical unit, Kasr el Aini Hospital, Cairo, were shown:

Professor A. K. HENRY showed: (1) A case of rectal prolapse treated by a modification of Lange's method of shortening the rectum from behind after removing the coccyx. (2) A case of shoulder-drop treated by slinging the scapula to the vertebral spines with two strips of fascia lata. (3) A case of talipes calcaneo-valgus stabilized by hinged grafts. (This case is recorded in detail at p. 663.) (4) A case of luxation of both shoulders, after birth palsy, in a girl aged 11, with a cinematograph film showing the skilled movements of the feet, with which she was able to feed herself and to sew.

Dr. AHMED EL SAYED HANDOUSA (Resident Surgical Registrar) showed slides to illustrate a simple way of fixing the tendons transplanted for varus deformity. Dr. Handousa's description of the device was as follows:

> The best way of fixing a transplanted tendon is to pass it through a hole in bone (Gallie and Le Mesurier, *British Journal of Surgery*, 1924, xii, 289). As the tibialis anticus is too short to be passed through the base of the fifth metatarsal bone in cases of varus deformity of the foot, the following device has been carried out to compensate for that shortness and to secure a very strong insertion to the outer side of the foot.
>
> The extensor hallucis longus, which Jones and Lovett recommend as an auxiliary, being a long tendon, is detached from its insertion and transferred to the outer side of the foot. It is drawn through a hole in the base of the fifth metatarsal bone, and its end is split into two limbs, as shown in Fig. 1. The two limbs are passed through a hole in the short tendon of the tibialis anticus, looped back and sutured to themselves and to that tendon. The extensor hallucis longus is again sutured to itself at A and B (Fig. 2). The ends of the two tendons, being now firmly attached to one another, are buried under the periosteum of the cuboid bone.

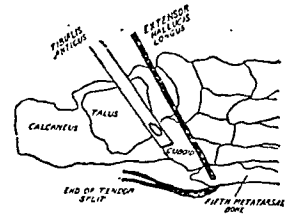

FIG. 1.

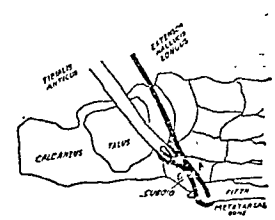

FIG. 2.

I am indebted to Professor A. K. Henry, director of the surgical unit, Kasr el Aini Hospital, who used this method for the *right* foot of the girl shown in Figs. 5 and 6 of his paper on hinged grafts, for permission to publish it. (See p. 664 of this issue.)

Reports of Societies.

THE ACETONE BODIES IN DIABETIC COMA.

AT a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland on March 18th, Dr. R. J. ROWLETTE in the chair, Dr. A. R. J. DUNGAN read a paper on the part played by the acetone bodies in diabetic coma.

Dr. Dungan gave a brief review of the literature to show that the actual part played by the acetone *bodies* in producing the symptoms of diabetic coma was very unsettled. Experiments were then described which indicated that dogs and cats could be free from symptoms while having in their blood concentrations of aceto-acetic and β-hydroxybutyric acids greater than those commonly found in human diabetic coma; it was concluded, therefore, that neither of these acids was likely to exercise a direct toxic effect in this condition. The experiments also showed that with the former acid, and probably also with the latter, when sufficient had been administered to a dog there resulted a curious delayed intoxication, leading to prostration and death, the latter commonly occurring at a time when the acetone bodies had almost disappeared from the blood. One feature of this intoxication was a resistance to the action of insulin, such as occurred in human diabetic coma. It was suggested that this latter condition might possibly represent a similar "indirect" intoxication with one or both of these acids. Further experiments with acetone were described which showed that the effects of this substance were totally different from those of aceto-acetic acid.

Dr. A. R. PARSONS said that he had always had great difficulty in getting oxybutyric acid in the urine, and asked if there was any danger of producing hypoglycaemia in a case of diabetes by pressing insulin, when the urine was full of acetone and diacetic acid, but only a very slight amount of sugar was present.

Dr. H. R. MICKS referred to the resistance to insulin which was sometimes met with apart from ketosis, and asked what caused this resistance. He mentioned a case recently reported, in which insulin had done very little towards lowering the blood sugar, and said it looked as though there was something else in the body, not a ketone, in diabetic cases which interfered with the action of insulin.

Dr. E. T. FREEMAN asked what was the behaviour normally in diabetic dogs in regard to the formation of ketone bodies, and if the effect of the ketone bodies in dogs in the advanced stage of diabetes was at all comparable with what it was in human beings, and if ketone bodies formed as rapidly in dogs as they did in human beings.

Dr. DUNCAN replied that cases of diabetic coma had been rather rare in the hospital in which he had worked in America; when they did occur the patients were given massive doses of insulin, and ketosis disappeared almost immediately. Large doses of insulin should not, in his opinion, be given to a patient who had acetonuria but was not in definite coma. He did not know what caused the resistance to insulin in some patients, unless it was gross pancreatitis, or carcinoma. He referred to the peculiar resistance of dogs to the action of narcotic drugs.

Aneurysms of Abdominal Arteries.

Dr. W. D. O'KELLY showed a specimen from a case of ruptured aneurysm of the iliac artery. A woman, aged 68, while in a tram one morning, became weak, went home, and died that evening. The necropsy showed a ruptured aneurysm of the left common iliac artery. Haemorrhage had apparently occurred first into the retro-peritoneal tissues; the peritoneum had later given way, resulting in extensive intraperitoneal haemorrhage. The heart was enlarged, and showed evidences of coronary disease, but the valves were comparatively healthy. There was atheroma of the aorta with the linear cicatrization typical of a syphilitic lesion.

Dr. T. T. O'FARRELL referred to a case of aneurysm of the coeliac artery, in which it had not been possible to make the diagnosis for some time after the man had been in hospital. He had been admitted as a case of anaemia, but ultimately the aneurysm was found, and he lived for about three weeks.

Dr. R. J. ROWLETTE considered aneurysm of the iliac artery comparatively rare. It was interesting that the patient had lived for ten hours after the rupture. Dr. H. F. MOORE asked if a Wassermann test had been performed, and Dr. A. R. PARSONS inquired whether a Wassermann test after death was reliable. Dr. O'KELLY stated that he did not attach much value to the Wassermann test performed on serum collected at *post-mortem* examinations.

Haemangio-endothelioma.

Dr. A. HALPENNY exhibited specimens of haemangio-endothelioma taken from a child, aged 8 months, who was admitted to hospital with two tumours, one above the superior angle of the left scapula and the other over the right deltoid. The former was about the size of a walnut, and was surmounted by a cutaneous naevus. The latter swelling was smaller, and the skin over it was normal. On palpation the tumours were found to be lobulated, and had the consistence of sebaceous cysts. The patient's mother stated that she had first noticed the swellings when the child was a week or ten days old; within the past two months they had noticeably increased in size. The tumours, which lay in the subcutaneous tissue, were removed, and the affected portion of skin over the larger growth was excised; they were solid, and were separated by a capsule from the surrounding fatty tissue. On microscopic examination of sections both tumours were found to have a fibrous capsula surrounding lobulated processes, and the periphery of the lobules presented the typical appearance of haemangioma hypertrophicum, showing proliferated capillaries forming columns of cells several layers deep, with a central lumen. The individual endothelial cells were rich in cytoplasm, and had roughly circular nuclei. The centre of the lobules had undergone endotheliomatous degeneration. The cells were no longer arranged in columns, but lay very much closer together, forming a conglomerate mass, and the more numerous nuclei almost filled the cells. There was no attempt at lumen formation.

TREATMENT OF MENORRHAGIA.

AT a meeting of the Liverpool Medical Institution, on March 17th, Dr. R. E. ROBERTS and Mr. ST. GEORGE WILSON contributed a joint note on the treatment by x rays of certain menstrual disorders, especially menorrhagia, with a report of thirty-four cases.

Emphasis was laid on the difference in technique adopted in patients of different age. In older patients the aim of treatment was to bring about an artificial menopause, while in patients under the age of 40 the aim was to avoid, if possible, any interference with fertility and to perform castration only as a last resort. Attention was drawn to the fact that a castration dose in a patient over 40 years would not be effective in a younger woman, thus increasing the margin of submaximal dosage in the latter; in a young patient the process of castration would take longer. In the group of older patients a permanent amenorrhoea was successfully brought about by x rays in every case; in younger ones amelioration of symptoms was produced in most of the cases by submaximal dosage, and it was rarely necessary to proceed to complete castration. Most of the cases had been treated unsuccessfully by other means before employing x rays. Reference was also made to the irradiation of the spleen as an adjunct to the treatment of excessive bleeding, and to the irradiation of the ovaries by very small stimulating doses in dealing with primary amenorrhoea.

Psoriasis.

Dr. R. W. MACKENNA, in a paper on psoriasis, regretted that, though psoriasis was one of the most ancient of all diseases, there was, as yet, no certain means of curing it. Its cause was still unknown, though a definite familial tendency to it was undoubtedly traceable in about 30 per cent. of cases. The determining cause of the first outbreak was usually some slight trauma, but after the first attack a patient was likely to suffer from recurrences for the rest of his life. The psoriasis papule, which was the initial lesion, was a characteristic pathological entity, and it should be possible to diagnose psoriasis from it. The appearances produced by systematic curetting (grattage) were extremely characteristic. The anatomical conditions on which these phenomena depended were demonstrated by a microphotograph of a section of a papule. The paper was illustrated by lantern slides and many coloured illustrations, and Dr. MacKenna gave an account of a series of experimental observations which had been carried out in his clinic at the Royal Infirmary, with the help of Dr. *Elizabeth Hunt*. They had not, however, succeeded in discovering any new and certain method of curing the disease.

JAMES MACKENZIE INSTITUTE.

ON March 22nd, at the James Mackenzie Institute for Clinical Research, St. Andrews, Dr. N. MCLEOD read a paper on abdominal pain and hyperalgesia, and dealt with some points in connexion with the actual state of affairs found within the abdomen in cases where there was disturbance of the viscero-sensory and viscero-motor reflexes. He divided the causes of pain in intra-abdominal disorders into two main groups, the mechanical and the inflammatory. The first group included the muscular movements of the gastro-intestinal tube, and he described two cases to illustrate the different types of pain experienced in disordered peristalsis as compared with exaggerated peristalsis. Referring to the production of abdominal pain by traction on the peritoneum by peritoneal bands and adhesions, he quoted cases of abdominal pain where such dragging had occurred but where the nature of the symptoms could only be explained by assuming that the cause lay in the exaggerated muscular movements in the wall of the intestine. He mentioned one case in which it was possible to assume definitely dragging or adhesions to parietal peritoneum though no symptoms had arisen. In the inflammatory group he discussed the mechanism of production and the localization of pain in local peritonitis, both visceral and parietal. Apparently the viscero-sensory reflex was similarly disturbed in both varieties, but in the case of parietal peritonitis there was an additional factor—namely, the involvement of the cerebro-spinal nerve endings in the extra-peritoneal tissue by direct spread of the inflammation. He concluded that in cases where the visceral peritoneum alone was involved the symptoms were those referable to the organ which was covered by the inflamed peritoneum, while in local parietal peritonitis pain was localized over the area of peritoneum affected.

three lemons is swallowed daily. Curetting, we learn, is a humiliating and unnecessary operation—inject lemon juice and attend to the diet. Lemon juice is the most marvellous disinfectant yet "unknown" to medical science. It cures piles, syphilis, and cancer; so that many pages of dictionary might have been saved by mentioning lemon juice under one heading: "panacea."

MEMORIAL VOLUME TO SIR WILLIAM OSLER.

LAST year Bulletin IX of the International Association of Medical Museums formed a memorial number to Sir William Osler; it contained numerous appreciations from his friends and admirers, more than a hundred successful illustrations, mainly of Sir William and of the title pages of his published books and papers, and an elaborately classified and annotated bibliography of his writings occupying 130 pages. This volume of more than six hundred pages, most successfully edited by Miss MAUDE ABBOTT, was published privately and noticed in these columns (1926, i, p. 879). The 1,500 copies of the first impression were exhausted within six months, and to meet the continued demand a second impression[10] became necessary. This opportunity has been taken to add ten appreciations and reminiscences, a new sonnet, "The Healer," by Marion Osborne, and three new illustrations, including a fine colour print of J. S. Sargent's great picture of Osler, W. H. Welch, W. S. Halsted, and Howard Kelly.

Among the new appreciations are contributions from Sir E. Sharpey-Schafer, Dr. L. G. Rowntree, and two from Dr. Lawrason Brown of Saranac Lake, a short one entitled "Osler and Trudeau," and an address delivered at the inaugural dinner of the Osler Club, Saranac Lake, N.Y., on December 9th, 1925, with many interesting personal reminiscences. Like Dr. Rowntree and many others, Dr. Lawrason Brown caught the habit of book collecting from his former teacher and friend.

As before, this interesting memorial to a great and deeply regretted personality is attractively got up, and it is clear why Miss Maude Abbott's real labour of love has been so entirely successful.

NOTES ON BOOKS.

IN his contribution to the study of heredity in tuberculosis[11] Dr. R. PLA Y. ARMENGOL, whose essays on tuberculosis were noticed some time ago (JOURNAL, September 27th, 1924, p. 579), maintains that tuberculous infection of the foetus is very frequent, if not constant, in cases of active tuberculosis in the mother, while children whose fathers are suffering from active tuberculosis present a specific predisposition to develop the disease. On the other hand, the inheritance of tuberculous infection or the predisposition to tuberculosis is not equivalent to disease, so that the aim of the practitioner should be to increase the resistance of the individual with a tuberculous inheritance or predisposition and enable him to transmit his resistance to his descendants.

In *The South American Handbook*[12] for 1927, edited by Mr. J. A. HUNTER, the would-be tourist or emigrant can obtain a wealth of information. The first chapter describes the continent, its seasons, its health, its lack of roads, and its facilities for travel, with a glossary of Spanish and Portuguese terms, a list of weights and measures, and the text of the Monroe Doctrine. A brief description of the places of interest at the ports of call on the voyage out leads to an alphabetically arranged account of the various republics and countries of South America, with their products, resources, and tours that may be made in them. The chapter on the Falkland Islands includes an account of Sir Doveton Sturdee's action in 1914, and the interesting information that the Argentine Government does not recognize the British occupation, and presents an annual protest against it. The emigrant to South America is warned to take special precautions, especially if moneyless, and speculative emigration is discouraged.

[10] Bulletin No. IX of the International Association of Medical Museums and Journal of Technical Methods. *Sir William Osler Memorial Number: Appreciations and Reminiscences.* Second impression. THE AUSTRALASIAN MEDICAL CONGRESS
OF THE
BRITISH MEDICAL ASSOCIATION,
DUNEDIN, NEW ZEALAND.

(Continued from page 628.)

THE SCIENTIFIC SECTIONS.

COMBINED MEETINGS.

FOURTEEN combined meetings were held during the Congress in order to enable the various sides of different medical problems to be considered. Dr. L. E. BARNETT, President of the Congress, took the chair at the sessions in which goitre, spastic paralysis, and cancer were the subjects of discussion.

Goitre.

The Sections of Medicine, Surgery, Radiology, Preventive Medicine, and Pathology met together to consider goitre, Dr. H. SUTTON (New South Wales) being the opening speaker.

Dr. Sutton said that enlargement of the thyroid had a district incidence in Australia. Similar geographical, geological, and rainfall conditions were associated throughout, goitre being limited to the coastal plains with heavy rainfall. The incidence in heavy rainfall areas was explained by the withdrawal of iodides from the soil. No information was available with regard to goitre in animals. While the evidence was in favour of the soil theory, the study of the water supplies in the northern tableland and north-west slopes in New South Wales suggested associated water supplies, tank or surface but not artesian water being concerned. In school children goitre was associated with good health; the incidence was well distributed throughout the population, and no association with previous illness had been detected. The lack of association with toxic thyroid meant that prevention had not been emphasized or even tested in New South Wales. The best test of a goitrous area was the incidence of the disease in boys, in whom it was always abnormal. Simple enlargement of the thyroid and exophthalmic goitre were to be clearly distinguished, no relation between them having been established.

Dr. C. E. HERCUS (New Zealand) had found goitre most abundant on the more or less gravelly plains and river flats, and along the narrower flood plains of the large rivers. District incidence was an established fact. The occurrence of simple and toxic goitres constituted a serious problem in many districts. From the study of the iodine content of some 500 samples of soil obtained from all districts in the Dominion, it was found that the amount of iodine in the soil bore an almost inverse relation to goitre incidence. Sedimentary soils, especially if sandy or gravelly, contained least iodine. A general survey of the iodine content of foodstuffs had been undertaken, and a comparative study made of the goitrous and non-goitrous districts. The foods richest in iodine content were edible seaweed, sea-fish, eggs, wholemeal cereal products, leafy vegetables, and milk. The findings had been checked by clinical studies of iodine excretion in goitrous and non-goitrous districts, and were in favour of the view that goitre was caused by an iodine intake deficiency. The problem was to meet this biological deficiency in such a manner as to be harmless. The universal use of salt containing 1 part of potassium iodide in 250,000 parts was recommended as a compulsory preventive measure.

Professor A. M. DRENNAN (New Zealand) dealt with the pathology of goitre and showed a series of illustrative slides of different types of pathological changes. He gave the results of work by C. S. Hicks, K. C. Roberts, and himself on the iodine content of normal and pathological thyroids obtained by operation or at necropsies. He showed how similar changes occurred as regards the histology and iodine content in *post-mortem* glands and in specimens obtained by operation, but insisted that the difference was one of "mass." The gland excised for clinical goitre was larger than a gland obtained at a necropsy, showing similar

changes causing no clinical symptoms. He described some work on the iodine content and histological structure of animal glands which indicated that in endemic areas the gland was poor in iodine as compared with the non-endemic districts. He showed how the hyperplastic, secretory, or active type of tissue was lower in iodine than the colloid, or resting type, and how a clinically "toxic" goitre might be a diffuse colloid of high iodine content, or a nodule goitre with active areas, the active parts being low in iodine, the colloid parts higher. A scheme of goitrous derangements of the thyroid was presented, based on the total mass of the gland, its histological structure, iodine content, and the pathological changes correlated with clinical disturbance. Deficiency of iodine was the most important initial factor. The thyroid exposed to such deficiency must respond in one of two main ways to maintain the necessary supply of hormone. It might uniformly increase the storage area to accommodate a larger supply of colloid which was at a lower iodine concentration. This produced the simple colloid goitre, a common response in the endemic form; it was a compensated gland, and might remain quiescent indefinitely. If the deficiency was marked the gland continued to enlarge and became noticeable. It was adapted to a low iodine intake; if excess of iodine was supplied it became overcharged with hormone, and toxic symptoms might appear. The condition then became a diffuse colloid toxic goitre. The gland might respond also by parts hypertrophying or by parts becoming "active secretory," discharging the hormone as it was made; so arose the nodular or adenomatous goitre. Iodine given to such a patient might, if the mass effect was sufficient, produce definite "toxicity"; the secretory areas making the iodine into hormone, and passing it into the circulation. The whole gland might become active secretory, perhaps compensating, but producing no reserve store. Any extra demand for hormone meant a larger active gland, the primary exophthalmic goitre. Iodine exhibited in this case was of temporary benefit, but did not effect a permanent cure. The place of iodine was in prevention, and the earlier it was used the better.

Dr. R. R. STAWELL (Victoria) distinguished simple goitre, adenoma in simple goitre, adenoma with hyperthyroidism, and exophthalmic goitre as suggested by Plummer. In simple goitre, the endemic type, symptoms were rare; the patients were occasionally either hypothyroid or showed nervous symptoms, but the basal metabolic rate was not raised. They could be treated with iodine, or with thyroid extract, or thyroxine controlled by determinations of the basal metabolic rate. The treatment of adenoma, whether simple or toxic, was surgical. There was often heart failure with auricular fibrillation, for which digitalis and quinidine were of doubtful value. The characteristic symptoms of exophthalmic goitre were not those of increased metabolic rate, such as tachycardia, but eye signs, nervousness, and crises (Plummer). They were attributed to the production of a hypothetical iodine-free product of the thyroid, and the condition was termed "dysthyroidism." In Graves's disease hyperthyroidism and dysthyroidism were both present. Medical treatment was unsatisfactory and Dunhill's subtotal thyroidectomy was the correct practice. Iodine was of value in the form of Lugol's solution; this was given in 10-minim doses, but a massive dose of 100 minims distributed over two hours was given in the case of a crisis. The cause of the disease was unknown; until it was understood surgical treatment was necessary.

Dr. CARRICK ROBERTSON (New Zealand) dealt briefly with the pathology of goitre, including the simple, adenomatous, adenomatous with hyperthyroidism, and exophthalmic forms. He recommended that every cardiac decompensation case should be thoroughly examined for thyroid enlargement. Adenomata and their cystic degenerations called for surgery. The whole thyroid should be exposed or palpated at the operation in order that smaller adenomata in other parts of the gland should not be missed; if they were overlooked they would grow and cause the so-called recurrence. Occasionally a wandering adenoma was found, usually under the sternum. In Graves's disease surgery was indicated, good technique being essential. Much loss of blood was serious; perfect haemostasis and gentle operating were essential in securing a low mortality rate. The exhibition of iodine for a short period before the operation, and for a few days afterwards, made for safety. The best time to operate was usually about a week after the course of iodine had been begun, in the "iodine remission." When it was necessary to operate after *x*-ray treatment, the fibrosis increased the difficulty of the operation.

Dr. C. C. ANDERSON (New Zealand) considered that radiologists could safely take up the position that radiotherapy was indicated as the main line of treatment in goitre, following the usual medical treatment. It could be employed no matter how bad the condition of the patient: the slight early cases produced the best results, although desperately ill patients often gave the most startling ones. A diffuse goitre of the colloid type did not always respond favourably to radiation, whereas in the ordinary parenchymatous type irradiation was useless, although these patients would probably give better results if an operation followed one or two applications of the rays. Another type of case—namely, that in which, despite operation, the condition had recurred—might receive some assistance from the radiologist. Until recently Dr. Anderson had used a current of 10 milliamperes, with 3 millimetres aluminium filtration, an alternate spark-gap of 6½ inches, and a focal skin distance of 12 inches. Each side of the gland was treated for four to five minutes, the thymus being included. The patient was observed until no further improvement followed, when the next dose was given; usually up to six doses would be employed in the course of twelve months, and this would be sufficient. Radium had not proved so successful, but was sometimes useful for treating the very nervous patient. The advantage of *x* rays lay in the great variety and shade of penetration and quantity of radiation which could be used, allowing of almost perfect accommodation to individual needs. Rest was an important factor and enhanced the action of the *x* rays.

Metamorphosis of Simple to Toxic Goitre.

This subject was discussed by the Sections of Medicine and Pathology, Dr. D. GIFFORD CROLL (Queensland) taking the chair.

Dr. S. V. SEWELL (Victoria), opening the discussion, referred to the extreme vascularity of the thyroid. It was possible, he said, that one duty of the thyroid might be to act as a detoxicating mechanism for the blood passing through it. Any physiological stress, such as menstruation, might be met by increased vascularity in a healthy gland, but if the gland was unhealthy hyperplasia might occur. An adenoma might be formed, and in later life, when the gland was atrophied, this adenomatous tissue might, if the occasion arose, produce thyroxine and hyperthyroidism result. Toxins, iodine treatment, and psychic stimulation were some of the many factors which might cause this hyperthyroidism. He then referred to the striking effects produced by the exhibition of adequate doses of iodine in cases of exophthalmic goitre. He mentioned Williamson's work, and said that should it prove to be substantially correct it would in no way invalidate Plummer's conception of the dysthyroidism of Graves's disease and its possible causal association with the presence of an incompletely iodized thyroxine in the blood stream.

Dr. A. H. TEBBUTT (New South Wales) read a paper on the morbid anatomy of tumours of the thyroid gland. He first dealt with the embryology and life-history, and gave an account of the orthodox view. He next discussed aberrant and accessory thyroid tissue and the tumours concerned, illustrating his remarks by numerous microphotographs. He showed four cases of lateral cervical thyroid tissue, all of which were pathological. In three no connexion with the thyroid gland proper could be established, and in three there was no evidence of pathological change in the gland itself. He suggested that in the earliest embryonic stage the thyroid cells were migratory, and established outlying nodules which came into close association with the cervical lymphatic system and lost their connexion with the thyroid gland. One interesting feature was the fact that in his cases the appearance of lateral cervical thyroid tissue was restricted to one side.

In support of Ewing's view that tumours of the thyroid might be embryonic or adult growths, and that both groups included adenomata and carcinomata, he showed specimens of various forms of malignant and benign tumours all of which appeared to be of the adult type. He demonstrated that the adenomata passed from the simple replacement of alveolar cells by lymphoid tissue through various stages up to the typical Riedel struma.

Dr. F. T. BOWERBANK (New Zealand) emphasized the great importance of the basal metabolic rate in relation to disease of the thyroid (1) in diagnosis, (2) to estimate the progress of the disease and the result of medical and surgical treatment, and (3) to determine the time to operate and the extent of operation. After mentioning briefly the methods of determining the basal metabolic rate, he showed several lantern slides of graphs illustrating his remarks. In conclusion, he stated that the basal metabolic rate was the most consistent of all the signs and symptoms of hyperthyroidism or thyrotoxicosis. Taken in conjunction with the clinical signs and symptoms it was a valuable guide in diagnosis, in the progress of the disease, and in estimating the time and extent of an operation, if required. A patient who gave a reading of over 115 (100 taken as zero) on two consecutive days had hyperthyroidism. The closed method was most suitable for the use of medical practitioners; its use, especially where operation was contemplated, would lower the mortality rate.

Dr. W. SUMMONS (Victoria) dealt with goitre in Gippsland, the wide littoral of the eastern portion of Victoria. Most of the thyroid enlargement discovered had conformed to the simple parenchymatous type. None of the children exhibited evidence of hyperthyroidism; the physical development was up to standard, and no defects were found that separated them in any way from children in other localities. He concluded that in Gippsland among school children of either sex endemic goitre of a simple parenchymatous type was prevalent. There was no associated undue prevalence of toxic goitre, but there was some inconclusive evidence that the thyroid hyperplasia might be an effort to counteract a state of hypothyroidism. An investigation was being conducted of the iodine content of water and food.

Diet.

Dr. E. W. GIESEN (New Zealand) took the chair for a combined meeting of the Sections of Medicine and Preventive Medicine to consider questions relating to diet.

Dr. P. H. BUCK (New Zealand) opened the discussion with a paper on the food of the Maoris. He said that before the colonizing expedition of 1350 A.D. the Maoris were in what was termed the food-gathering stage. The food-producing stage was marked by the difficulty of growing foods such as the kumara, which were of tropical origin. Mammalian food was scarce, almost the only land mammal eaten being man himself. Fish and shellfish were eaten whole, and with the liquid contained in the shell formed the staple food supply. They were gathered in their proper seasons, and some of them were preserved by drying. Almost every kind of bird was eaten, the principal ones being the wood-pigeon, the parrot, and the tui. The entrails were cooked and eaten with the bird. Birds were preserved in their own fat for reserve supplies. The cooked and beaten rhizome of the New Zealand bracken was the most important source of carbohydrate. It was chewed and the fibrous material was rejected. For green vegetables they used the top of the taro, the sow-thistle, and leaves of *Solanum nigrum* and of other plants. Fruits and berries of the karaka, tawa, and hinau were also used. Food was cooked by means of the earth oven, a process which amounted to steaming; grilling was also used. There were two meals a day—one in the morning and one in the late afternoon. For variety of food an interchange was often made under the form of gifts. Fresh stream or river water was the only beverage. The Maori had to procure his foods for himself, his foods were hard and fibrous, and thus arose the necessity for chewing. The result was a magnificent bodily physique.

Dr. R. W. CILENTO, Director of Public Health in the Territory of New Guinea, reporting on diet and nutrition in Northern Melanesia, said that the native diet had been shown by analysis to be deficient in protein, fat, in vitamins A and C, and in salt; only irregularly were there additions which compensated for these deficiencies. There was, moreover, an increasing diminution in the supplies of flesh foods. He correlated these deficiencies with the poor physique of the natives, and with the high death rate from respiratory and intestinal diseases. He considered that the racial susceptibility to disease was due to dietary deficiencies rather than to any inherent lack of racially acquired immunity. In support of this he stated that the tendency to tuberculosis disappeared when the natives emigrated to a land where food supplies were more adequate. But for the liberal supply of sunlight the conditions would be much worse.

A paper on the relation of gastric function to the chemical composition of the blood, prepared by Dr. F. L. APPERLY (Victoria), was read by a delegate. It was stated that the existence of a relation between blood chemistry and gastric function was probable. If the bicarbonate content of the blood was increased the tone of the stomach muscle was also increased. In hyperpnoea from cardiac and other causes the alveolar carbon dioxide and plasma bicarbonate were low, and anorexia and vomiting were common. He had found that the plasma bicarbonate varied directly with the total chloride of a test meal, up to one and a quarter hours. Since gastric tonus varied with total gastric chloride it must also vary with the plasma bicarbonate. Also high acidity led to rapid emptying of the stomach, and a high plasma bicarbonate was found at the same time. The chloride of the blood appeared to vary inversely with that of the stomach, and patients with gastric hypotonus had low plasma bicarbonate and high chloride. Injection of ammonium chloride reduced the plasma bicarbonate and also gastric acidity and tonus, while rebreathing did the reverse. These experiments had therapeutic applications.

Professor H. P. PICKERILL, C.B.E. (New Zealand), in a paper on diet as a cause of sepsis in the alimentary canal, said that highly prepared, non-sapid carbohydrate food underwent lactic acid fermentation in the mouth, and failed to stimulate the alkaline saliva which would neutralize and wash it away. Taste was important in digestion, and non-sapid food did not stimulate the glossopharyngeal nerves. Organic acids were required for this, and they were lacking in such food; much alkali was present in food and used in drugs. Such food led to salivary stasis and bacterial growth. He thought that the toxins produced stimulated the sympathetic, which would explain the syndrome of intestinal toxaemia.

Dr. S. A. MOORE (New Zealand) believed that the "optimum tonic diet" excluded all denatured food; included abundance of the protective foods, such as contained fat-soluble A, calcium, no excess of muscle, but included the viscera of animals; and provided raw food as a salivary stimulant at the end of the meal. The errors in modern diet might not lead to obvious effects, but they tended to the gradual deterioration of the individual or of the race, providing fit soil for the incidence of the more conspicuous diseases. He testified to the value of the optimum tonic diet in cases of alimentary, renal, and other disorders, and hoped that the next congress would deal with the parts played in health by exercise, ventilation, rest, psychology, posture, and diet.

Dr. T. RUSSELL RITCHIE (Samoa) attributed the splendid physique of the Samoan to the plentiful food supply and to the hard work necessary to secure it. The diet was largely vegetarian, with occasional additions of fish and meat. There were no deficiency diseases among the Samoans, but it remained to be seen what effect would be produced by the recent tendency to eat imported foodstuffs. If there had been any deterioration in physique it had been due to hookworm, which was now, however, being controlled. The danger age for children was between 6 and 18 months, when marasmus was common through the sudden transference to adult diet, but by public health advice on diet the infant mortality had been reduced from 200 to 120 per 1,000 in two years.

Dr. ELIZABETH GUNN (New Zealand) said that she had held six health camps, each of between four and six weeks' duration, for a total of 550 children suffering from malnutrition. The general principles on which the camp was

run included the supply of plain but wholesome food and the keeping of regular hours, with plenty of sleep. Children who on arrival were nervous, food-faddy, and irritable put on weight and improved in general health in an astonishing manner. Some, previously regarded as mentally backward, were now up to their average age in classwork. She had had remarkable results with a milk class, where fifty undernourished children were each given half a pint of milk a day.

Pulmonary Tuberculosis.

Dr. G. J. BLACKMORE (New Zealand) opened a discussion on pulmonary tuberculosis in infants and children at a combined meeting of the Sections of Pediatrics and Radiology. He said that in the course of seventeen years out of 1,800 patients with pulmonary tuberculosis only thirty-seven were below the age of 13. No great difference existed as between adults and children; the same diagnosis applied equally to both. In dealing with diagnosis he emphasized the fact that infection could be proved by reactions to von Pirquet's and Moro's tests. The relative frequency of bovine and human infection varied greatly in different countries. Tuberculosis was essentially a disease contracted in childhood, the adult being relatively immune to infection. When it became manifest in an adult it was in the great majority of cases a recrudescence of disease contracted in childhood. Infection occurred almost entirely indoors; it was therefore the home conditions during childhood which they had to consider if infection was to be prevented. They must deal with the child if they wished to prevent the infection from becoming a serious disease and to abolish adult tuberculosis.

Dr. C. C. ANDERSON (New Zealand) exphasized the fact that in radiography error was caused by comparing the appearances in the chest of a child with those of an adult. Pulmonary tuberculosis could be shown once the tubercles began to form, but the difficulty was to know how to distinguish the early pathological appearances from those of the normal or average chest. He believed that lesions commenced in very young children in the lower lobe and spread centripetally to the hilum; cases of miliary type were rare. He showed various radiographs to illustrate the difficulty in making a diagnosis, and suggested that the radiographs of New Zealand chests differed from those of the Old World chests on account of the greater acuteness of the infection met with in the former country.

Dr. J. F. MACKEDDIE (Victoria) gave a demonstration to a meeting of the Sections of Medicine and Radiology of artificial pneumothorax, which was illustrated by cinematograph films. He said that the long-delayed acceptance by British workers of this means of treatment was due to division of opinion as to the class of case most suitable for it, and to the dangers attendant upon it. Less harm would result from its more frequent use than from wholesale neglect of it. It required unsparing x-ray help; and before practising it the operator should have a sound knowledge of anatomy and pathology derived from necropsy experience. The cinematograph film showed Lillingston's apparatus and the detailed method of performing the artificial pneumothorax. An account of the difficulties encountered and the means of dealing with them was followed by x-ray pictures illustrating the use of artificial pneumothorax in breaking down adhesions, in performing simultaneous filling and evacuation, and in the treatment of lung abscess. The question of refills, the rate of compression, the optimum compression point, the choice of gas and of needle, and the use of lipiodol by the laryngeal or preferably by the tracheal route, were fully discussed.

Hydatid Disease.

A combined meeting of the Sections of Medicine and Radiology was held to consider the medical aspects of hydatid disease, the performance of artificial pneumothorax, and some points in connexion with the examination of the cerebro-spinal fluid.

Dr. R. R. STAWELL (Victoria) opened the discussion on hydatid disease by enumerating the criteria on which diagnosis was based; these included the toxic (anaphylactic) symptoms, the x-ray examination, the complement fixation test, the Casoni test as interpreted by the Melbourne workers, and the occasional presence of eosinophilia and of hydatid hooklets. The toxic symptoms and the manner of their production and manifestation were fully discussed with reference to differential diagnosis. The "hydatid diathesis" was contrasted with the anaphylactic condition. The physical signs and symptoms which should make the physician suspect and link up the diagnosis, and the pitfalls in complicated cases, were mentioned. By using all diagnostic resources the error of diagnosis in Melbourne Hospital had been reduced from 40 to 2 per cent. Since the infestation occurred during childhood directly from dogs, which had been infected from eating the raw offal of sheep, the only plan of prevention was to prohibit the feeding of dogs with hydatid-infected raw material.

Dr. H. R. DEW (Victoria) said that the toxic manifestations following rupture or puncture of a hydatid cyst were to be attributed to anaphylaxis; they could not be due to that small amount of ergotoxin-like substance which was present in hydatid fluid, for the absorption of quite minute amounts could produce the symptoms. The initial absorption which produced the sensitization probably occurred in the early stages of embedding of the parasite before it became walled off from the surrounding tissues. This sensitization was present in 90 per cent. of cases (as determined by the Casoni test), but varied greatly in degree. Leakage due to trauma, puncture, or surgical intervention produced anaphylactic symptoms of benign, severe, or of the gravest character, depending on the amount and rapidity of the absorption and the degree of sensitization. The type and range of symptoms—cutaneous, gastro-intestinal, respiratory, cardio-vascular, and nervous—were described. He stated that general anaesthesia greatly reduced or abolished the anaphylactic state, but after the anaesthesia had worn off symptoms might occur. It was important to remember that the exploratory puncture of even a small cyst was dangerous, and that the degree of sensitization varied greatly. An operation under local anaesthesia was not without risk. The mode of reaction to the Casoni test might prove to be a useful pre-operative guide.

Dr. NEIL GUTHRIE (New Zealand) dealt with the x-ray examination of intrathoracic and subdiaphragmatic hydatid disease and its complications. He said that though he was especially interested in the x-ray aspect, he advocated a combination of all resources in diagnosis. Contrary to textbook impressions, pulmonary cysts were not always readily seen. Uncomplicated cysts might be masked by the heart or might be mistaken for pleural effusion or hyperplasia with a primary or even a secondary sarcoma. The difficulty was increased by complications such as suppuration, spontaneous rupture into the pleural cavity with or without cicatrization, and rupture from an exploratory needling when there had been no previous radiographic examination. Abdominal cysts might be seen if they were on the upper surface of the liver or spleen; a lateral as well as an anterior or posterior view was required. They might be missed after rupture or suppuration, or might be confusing if calcification had occurred. Use might be made of pneumo-peritoneum or of the displacement of a cyst by the barium-filled stomach or intestine.

The diagnosis and surgical aspect of hydatid disease formed the subject of another combined meeting, in which the Sections of Surgery, Radiology, and Pathology took part.

Dr. C. H. KELLAWAY (Victoria) opened the discussion with an account of the diagnostic tests in this disease, with special reference to investigations of the immunological aspect of hydatid infestation in progress at the Walter and Eliza Hall Institute, at Melbourne, of which he is director. In the earliest stage of the disease the only test likely to be of value was the intradermal, which might give a delayed as well as an immediate response; eosinophilia might also be present. At a later stage, when there was a large uncomplicated cyst, with intact laminated membrane and thickened adventitia, there was, as a rule, no eosinophilia, but both phases of the skin

reaction were observed, except in rare cases when the cyst fluid was of low antigenic power. With the formation of daughter cysts, eosinophilia might be present; there might be a reaction to the complement fixation test and often a high titre of antibody might be revealed. The Casoni test might for some time give only an immediate wheal, though later both phases of the skin reaction might be found. Rupture or suppuration might be quiet, with continued absorption of the antigen for long periods, or they might occur suddenly with the production of anti-anaphylactic phenomena due to the outpouring of antigen. The complement fixation reaction was usually positive, indicating a high titre of circulating antibody. The intradermal test might fail, though the appearance of the immediate wheal without any delayed response was common. After some months, when the absorption of antigen had greatly increased, both the immediate and delayed reactions occurred. After death of the parasite or cure by operation, the amount of complement fixation might be small or absent, though the result of the Casoni test, both immediate and delayed, would continue for some years, the delayed response usually being the first to disappear. The Casoni test was of little value when there was a previous history of hydatid infestation, but it was most valuable in early and uncomplicated cases. In complicated cysts, or in cases of recurrence, or of residual cysts, the complement fixation test was of the greatest value. The simple precipitin test of K. D. Fairley was useful where there was no accommodation available for the employment of the complement fixation test.

Dr. P. CAMERON (New Zealand), speaking from the radiological standpoint, referred to intrathoracic and abdominal diagnosis; he emphasized the necessity of correlating a clinical examination and the clinical test for hydatids with the *x*-ray evidence in making a differential diagnosis. Mention was made of the therapeutic value of *x* rays in preventing transplantation following operation; this was not practicable in the liver region.

Sir GEORGE SYME (Victoria) dealt briefly with the history of the treatment of hydatid disease. The ideal treatment consisted in completely extirpating the parasitic cyst with its contents and pericyst entire, closing the incision without drainage. In cysts in the kidney and spleen he recommended Bond's operation, and for the majority of liver cysts Hamilton Russell's operation.

The Cancer Problem.

Professor P. MACCALLUM (Victoria) opened a discussion on the present position as regards cancer; all Sections concerned were invited to take part. He referred to the great public interest in the cancer problem, which indicated the magnitude of the effort being made to solve it. Statistical records showed a steadily increasing cancer death rate in many countries, but this could be explained by better diagnosis and the survival of more people to the cancer age. Though there had been a steady increase in the cancer group, some individual cancer types had actually shown a definite decline. He referred to Miss Slye's work on heredity in relation to cancer, and to Dr. Gye's work on the filter-passing virus and chemical specific factor. Tissue culture studies were yielding results of great importance, notably Warburg's research into the metabolic processes of cells, and Heaton's investigation of the factors affecting the multiplication of fibroblasts and epithelia. Efforts directed especially to treatment had received much attention; he mentioned Blair Bell's lead treatment, Lumsden's immunological work, and the radiological investigations. The search for a general clinical test that would be of value in the diagnosis of cancer had so far been comparatively unrewarded. Botelho's serum reaction had so far proved the most successful of a number which had been elaborated; none so far had been found to have any dependable value as a clinical aid. There was much need for the dissemination of knowledge of early symptoms.

(To be continued.)

Lister Centenary Exhibitions.

WELLCOME HISTORICAL MEDICAL MUSEUM.

IN the Hall of Statuary of the Wellcome Historical Medical Museum in Wigmore Street, London, a remarkably full collection of objects of interest connected with Lister's career has been brought together by the conservator, Mr. L. W. G. Malcolm, and was opened on Monday last. This consists of photographs and portraits of Lister, of his family, and of the houses he lived in, testimonials and diplomas, etc., and instruments used in his researches, together with specimens of the various dressings and ligatures introduced and used by him at various times. There are also many photographs of his associates.

Portraits and Groups.

Of the portraits the most striking is the oil-painting of Lord Lister painted by J. H. Lorimer, R.S.A., which has been lent by the University of Edinburgh, to whom Lister bequeathed it. It was presented to him by his former colleagues and pupils of the University in July, 1895, on his retirement. Another most interesting oil-painting, by Gsell, has been lent by the French Government. It represents the embrace of Pasteur and Lister on the occasion of the celebration of the jubilee of the former in Paris in 1892. The likeness of Pasteur is striking, but the face of Lister is not visible. This is a much more realistic representation of the group of chief actors in the memorable scene than that in the large, almost panoramic picture (see p. 659) of the whole assembly at the Sorbonne, of which also a reproduction is exhibited. Among many other portraits the silhouettes of members of Lister's family are interesting, and particularly so is the original of the delicate and charming portrait of his mother, drawn by his father, which was reproduced in Sir Rickman Godlee's biography. The painting of Upton House, West Ham, where Lister was born, and a number of other views of the house and grounds remind us of the vast changes that have occurred in the neighbourhood of all great towns in the last hundred years. Relics of his funeral are shown, lent by the Glasgow Lister Memorial Committee.

Photographs illustrating his professional and academic career are also exhibited. Lister was an honorary fellow or member of nearly every society interested in natural science or medicine or surgery in the world, and the diplomas and certificates which accompanied these honours cover a large space of the wall of the exhibition room. Here are portraits of a large number of those whose names were best known in surgical circles in all countries in the last century, as well as of those less celebrated whose privilege it was to act as his assistants, house-surgeons, and dressers.

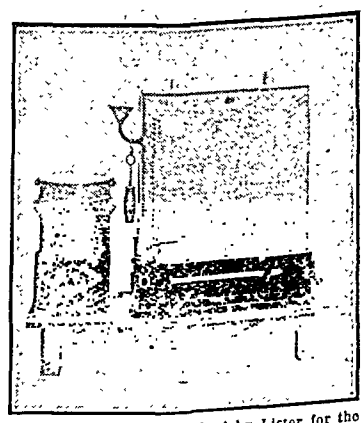

FIG. 1.—Machine as devised by Lister for the preparation of antiseptic gauzes.

Early Apparatus.

In cases on the floor and sides of the hall are some of the original apparatus which Lister used in his investigations, or facsimile reproductions of them, such as his machine for preparing sterile antiseptic gauze. By means of this apparatus, which is shown in Fig. 1, the gauze was

sterilized by heat and the antiseptic substances or liquids diffused throughout its substance. In Fig. 2 is shown the "hot-box," as Lister called it, which he devised for the incubation of microbes. This rudimentary apparatus was the forerunner of the incubator or autoclave of the present

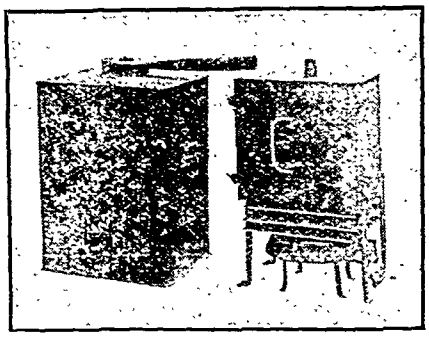

FIG. 2.—Lister's hot-box.

day. It had no thermostat by which the heat could be regulated and kept at any desired point on the thermometer. It was heated by a gas-ring, the flame of which was kept from contact with the box by several thin metal plates or false bottoms, which may be seen in the figure.

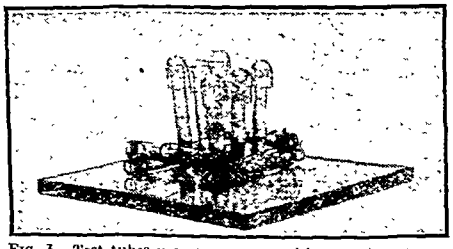

FIG. 3.—Test tubes used by Lister in his experiments on lactic fermentation.

Apparently the only means of keeping the temperature nearly constant was the tap on the gas supply. Rudimentary and rough as this apparatus was, some very good work was done with its help. Fig. 3 shows a group of glass tubes covered by loosely fitting glass caps, but not really sealed in any way. In these, after many trials, Lister succeeded in keeping milk free from fermentation without the aid of chemicals or heat. With their aid he studied the phenomena of lactic acid fermentation.

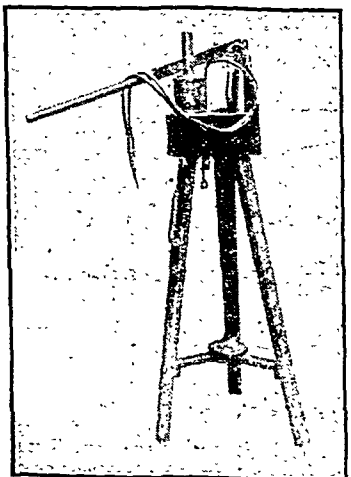

FIG. 4.—Pump spray ("donkey engine") as used by Lister.

Soon after he began to use the carbolic spray during operations, he found that the hand spray, which had been devised by Sir Benjamin Ward Richardson as an ether-freezing apparatus, was inadequate, and that it put the neuromuscular systems of his dressers to too severe a test. He then devised what became known as his "donkey engine," which is shown in Fig. 4. It will be seen that this was worked by a lever in the hands of an assistant, somewhat after the fashion of a primitive fire-engine. He also used a spray worked by foot-bellows, a specimen of which is in this exhibition. The steam spray was the last stage in this evolution, two of the earlier types of which are shown in Fig. 5. Still larger and more elaborate engines were finally employed, but they did not differ in principle from these two. Specimens of his catgut ligature containers are also among the exhibits.

We are struck by the simplicity but practical usefulness of some of these things; by studying them and the collection of dressings and chemicals the evolution of antiseptic surgery may be followed step by step. Although some, like the carbolic spray, whether worked by hand, foot, or steam, have been left behind in the ascent, yet they had their uses in the successive stages of the arduous climb towards that perfection which is not likely ever to be quite reached.

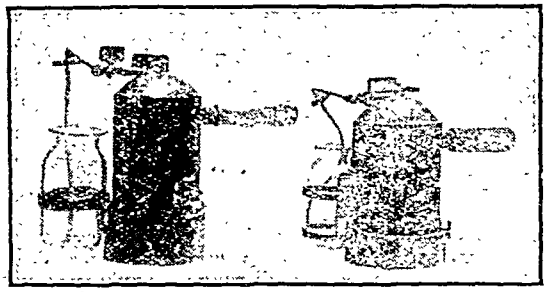

FIG. 5.—Steam sprays as used by Lister.

The Patents of Baronetcy, of Barony, and of Arms of Peerage of the Realm are also exhibited, with the proud motto: "Malo mori quam foedari," which may be freely rendered as "Death before dishonour."

The Lister Ward.

The greatest triumph of this remarkable exhibition is the reconstruction of the essential part of the Lister Ward at Glasgow out of the original materials and with much of the original furniture and equipment, which preserves indefinitely the scene where pyaemia and other hospital diseases were once rampant, where "Died" was a much commoner end of the clinical record than "Discharged" until Lister's antiseptics banished those scourges from it. Besides this section of the actual building (of which a photograph is reproduced at p. 685), a remarkably effective diorama gives the onlooker a very realistic impression of the whole ward.

We are informed that the exhibition, which on Thursday last was the scene of a reception at which Sir StClair Thomson and Professor A. Young gave addresses under the Presidency of Sir W. Watson Cheyne, is to remain open until May.

The photographs illustrating this article are the copyright of the Wellcome Historical Medical Museum.

THE LISTER INSTRUMENTS AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

This collection of instruments which had been Lister's was bequeathed to the College by his nephew and biographer, Sir Rickman Godlee. Besides the customary armamentarium of a surgeon the collection includes a number of appliances which were devised for special purposes by Lister himself. His abdominal tourniquet, which he had made for use in a case of iliac aneurysm in which he assisted his father-in-law, Syme, in Edinburgh, was very efficient, but he was not satisfied with this first pattern and modified it again and again. It was not till some time later that he found that he had been anticipated in the invention by Pancoast of Philadelphia. His sinus forceps, which has become a standard instrument, was devised for extracting small sequestra and for the introduction of drains of various kinds. These may almost be called delicate instruments, and they require excellence of material and workmanship for efficiency. His urethral forceps for the removal of calculi from the prostatic portion of the urethra was a very efficient and well devised

instrument. One of its chief merits was that when the blades were separated and the calculus was grasped, the shank took up less room in the urethra than when the blades were closed. This gave the operator more freedom of manœuvre than an ordinary forceps would allow. The lithotrite which he used was copied from one exhibited by Bigelow when he visited London. He had a special hook made, which he inserted into the tendon of the quadriceps cruris, just above the upper fragment of a fractured patella, with which he drew it down into apposition with the lower fragment before twisting his wire sutures. His work in the treatment of fractures and diseases was that of a pioneer. The long steel or iron pegs which he used as a temporary means of fixing fractured bone ends in position are remarkable from the fact of their being square in section. They were driven into round drill-holes, and he considered that they were easier to insert than round pegs or nails. Also their shape left room for the escape of blood or serum from the bone.

Lister had his own form of hernia knife and special retractors to be used in suprapubic lithotomy, which he did much to reintroduce. He devised modifications of cleft-palate needles and urethral sounds for the dilatation of strictures.

An account of these instruments at the Royal College of Surgeons of England has been written by Mr. C. J. S. Thompson for the Lister Centenary celebrations this week at Boston, Massachusetts.

A LETTER BY LISTER.

THE letter reproduced in facsimile on this page was written by Lord Lister in his own hand to the Editor of the BRITISH MEDICAL JOURNAL on the day following the publication of the *Lister Jubilee Number*, which bore date December 13th, 1902.

Joseph Lister passed the examination for the degree of Bachelor of Medicine of the University of London in November, 1852, and was admitted a Fellow of the Royal College of Surgeons of England on December 9th of that year. It was therefore thought appropriate to celebrate the jubilee of his entrance into the medical profession by publishing a special number of the BRITISH MEDICAL JOURNAL which should contain some tributes to his great service to surgery, and through it to suffering humanity, and some account of the steps by which these great results were attained. That issue included as frontispiece a reproduction of the portrait by Hugh Riviere, for which Lord Lister gave the artist several special sittings; the original is in the possession of the British Medical Association, and hangs in the Hastings Hall of its House at Tavistock Square.

Several distinguished foreign surgeons contributed valuable papers to the special issue of December 13th, 1902, including Ernst von Bergmann, Professor of Surgery in the University of Berlin; M. Lucas-Championnière, Surgeon to the Hôtel-Dieu, Paris; Oscar Bloch, Professor of Clinical Surgery in the University of Copenhagen; Professor von Mikulicz-Radecki, of the University of Breslau; and Professor Francesco Durante, Director of the Surgical Clinic in the University of Rome.

12, PARK CRESCENT,
PORTLAND PLACE.

14 Dec 1902

My dear Dr Williams.

I must tell you how very much the Jubilee number has gratified me. It pleases me not only because "dulce est laudari", but much more because it seems to me calculated not only to interest but also greatly to profit many of your readers.

Your editorial words are enough to make me blush, and you must allow me to express my admiration of the way in which you have managed this by no means easy undertaking.

Believe me
very sincerely yours
Lister

Dr Dawson Williams
British Medical Journal
429 Strand
W.C.

Other tributes to Lister and his work were contributed by Mr. Howard Marsh, Surgeon to St. Bartholomew's Hospital and afterwards Professor of Surgery at Cambridge; by Sir Alexander Ogston, Regius Professor of Surgery in the University of Aberdeen and President of the British Medical Association in 1914; by Dr. D. Berry Hart, Professor Thomas Annandale, and Professor John Chiene of Edinburgh; by Sir Hector C. Cameron of Glasgow; and by Sir William Watson Cheyne, a successor of Lister in the Chair of Clinical Surgery at King's College, London.

British Medical Journal.

SATURDAY, APRIL 9TH, 1927.

"LET US NOW PRAISE FAMOUS MEN."

THIS exhortation from the ancient commendation of benefactors has been duly observed recently. The celebration of the two hundredth anniversary of the death of that intellectual giant Newton is scarcely over when we find ourselves commemorating the centenary of the birth of Joseph Lister. Some of Newton's earlier researches were concerned with the refraction of light, the problems of achromatic vision, and the production of achromatic lenses for telescopes. It was reserved for Lord Lister's father, Joseph Jackson Lister, to solve these problems as regards the microscope, and to establish claims to scientific eminence which had been almost overlooked in the brilliance of the achievements of his distinguished son until Lord Lister himself did them justice in the *Dictionary of National Biography*. Newton and Lister were both men of modest disposition, not quarrelsome, although not to be shaken in the convictions which they had arrived at by experiment and their powers of reasoning. Lister feared no man or woman, and when Queen Victoria, by the pen of one of her court, wrote strongly urging him to denounce the practice of vivisection, he replied with an outspoken defence of experiments upon animals, couched in the plainest and most uncompromising language, which remains one of the best statements of the case for experimental physiology ever written. Newton had to contend against the overweening claims of that erratic genius Hooke and the criticism of others, but he so much disliked controversy that he long deferred publication of some important discoveries. Lister, in his long and hard struggle to convince contemporary surgeons of the truth of his contentions and the enormous value to mankind of his discoveries, did not become bitter, nor even lose that sweet reasonableness which was inherent in his disposition, and was doubtless fostered by his upbringing in the Society of Friends and by the example and teaching of his Quaker parents. The impressions of his youth were indelible, and although he formally left the Society on his marriage, he did not abandon some of their fundamental principles or their forms of speech.

Not long ago, in considering Sir Berkeley Moynihan's Hunterian Oration ("Hunter and Lister," BRITISH MEDICAL JOURNAL, February 19th, 1927, p. 343), we referred, as did Sir Berkeley Moynihan, to Lister's work in physiology, for not only was he a distinguished physiologist, but one of the founders of the modern science of bacteriology. Throughout the most active part of his career, when his time was much occupied in the practice and teaching of surgery, he, with prodigious industry, continued his exact and careful researches into the nature and growth of fungi and the problems of lactic and some other fermentations. Small wonder if, as his biographer, Sir Rickman Godlee, has told us was the case, his private practice suffered from his lack of punctuality. The number of his achievements has to some extent obscured their importance. His work as a physiologist on inflammation and on the coagulation of the blood was notable enough of itself to have secured him fame. Equally notable were his investigations in micro-pathology and fermentation. The advances he made in operative surgery, and especially in the surgery of bones and joints, were numerous and important enough to have made the reputation of any hospital surgeon; but all these were overshadowed by his great achievement in the control of diseases and septic processes, and in the invention of the aseptic absorbable ligature, the use of which made secondary haemorrhage after the tying of arteries a surgical rarity, instead of an ever to be dreaded accident in all cases of amputation.

Lister was ever ready to sacrifice his personal comfort and pecuniary advantage to what he felt to be his duty to his fellow creatures. As Professor of Clinical Surgery in Edinburgh he held a position which left little or nothing to be desired. A large private practice, a great reputation, splendid hospital opportunities, and the love and admiration of a great class of students who hung upon his words—all were his. The death of his father broke the last strong bond that bound him to London; but he doubtless felt that the leaders of surgery in London would not be converted until he could place a great object-lesson before their eyes, and that to do so he must sacrifice much in order to return to the scenes of his youth. A chilly welcome awaited him in some quarters. Instead of the crowds of enthusiastic students and practitioners who listened to him and watched his practice in Edinburgh, he had to be content with the attendance of a bare dozen at his lectures and operations. His colleagues on the staff of the hospital were at best coldly and critically courteous, and a section of the medical press was decidedly hostile; but we are proud to recall the fact that this JOURNAL urged the authorities of King's College to make the appointment, and when they had done so we wrote (BRITISH MEDICAL JOURNAL, October 6th, 1877, p. 490): "The selection which the authorities of King's College have made has done honour to their judgement and will add largely to the usefulness and lustre of their school; while it adds also to the glory and the greatness of the surgical profession in London, from which Mr. Lister sprang and to which he returns." Two years later, in commenting on the discussion opened by Sir William (then Mr.) MacCormac, at a meeting of the South London District of the Metropolitan Counties Branch of the Association, we wrote as follows: "We heartily congratulate ourselves and the profession that Mr. Lister's coming to London has been so speedily followed by a signal triumph of that great principle in surgery which had been accepted everywhere else almost before it was even listened to in London. It was with the conviction that this necessary triumph would follow that we strongly urged the authorities at King's College to put aside small traditions and petty jealousies, and to invite the great London surgeon, who had succeeded Syme in Edinburgh, to assume the mantle which had fallen from the shoulders of Fergusson in London. In doing so, the authorities of King's College had to brave much opposition, to have the courage of their opinions in the face of objections and deprecatory communications from persons eminent in professional standing; but they obeyed what we believed then, and are still convinced, to have been a sound law, and set an example which we hope will have a permanent influence in elevating the tone and strengthening the principles of responsibility in public appointments in London hospitals. Mr. Lister has been but two years in London, and already he may say that he 'came,

saw, and conquered'; for the principle of antisepticism has now so strongly asserted itself in London hospitals that it is bound to make its way and to establish itself here as firmly as elsewhere throughout the world. . . . this meeting will remain an historic event in the records of British surgery."

Glasgow, of which the hospital authorities did not show a due appreciation of Lister while they had him on the staff of the Royal Infirmary, last week celebrated his centenary with enthusiasm, tempered no doubt with regret that a few obstructives had destroyed the ward in which his first victories were won. Glasgow's loss is London's gain, for all that is left of the ward has followed its hero hither, and as reconstructed has been seen by hundreds at the Wellcome Historical Medical Museum during the celebration this week. Not only did Lister revolutionize the treatment of wounds and immeasurably enlarge the frontiers of the realm of surgery throughout the world, but we believe that he has changed the attitude of surgeons towards natural science and widened their views, so that they now approach surgical problems in a very different spirit from that of some of the leaders of the profession sixty years ago. Surgery when Lister went to Edinburgh was still, as it had been for many centuries, to a great extent a handicraft. He applied the experimental method to it and gave it an insight into the discoveries of Pasteur and an interest in scientific discovery which it has not lost, and, we feel sure, never will lose. Truly he was a great and good man, and we may say with one of his patients, W. E. Henley:

> "We hold him for another Herakles
> Battling with custom, prejudice, disease,
> As once the son of Zeus with Death and Hell."

THE MANY-SIDEDNESS OF LISTER.

THE three discourses delivered during the celebration in London of the centenary of the birth of Lister by three of our leaders in physiology, pathology, and surgery are published in the opening pages of this issue of the JOURNAL. In the article immediately preceding this we remark on the number of branches of scientific research in which Lister distinguished himself, and refer to his work in physiology, to which he made valuable contributions at an early age. It is satisfactory to find so high an authority as Sir Charles Sherrington dwelling on the importance of Lister's physiological researches and praising the skill with which he carried them out. These physiological investigations had no obvious bearing on the great work which was to follow, but they were not only evidence of his acumen, but also afforded him valuable experience and self-training in scientific method. At this time, notwithstanding the fact that he had been educated in what was then one of the most inspiring of the London medical schools, surgery had not fired him with enthusiasm. It was not until he had been some time at Edinburgh working under Syme that he wrote home to his father that he had fallen in love with surgery; but physiology was certainly his first love. In his work on the muscle of the iris, on the skin and hair follicles, and on smooth muscle, that clearness and simplicity of language and restraint of statement is evident which distinguished his work throughout his career. The Quaker training, with its respect for the injunction, "Let your communication be. Yea, yea; Nay, nay," may have had something to do with this by strengthening his innate love of precision and exact truth, and his fear of nothing except of missing the truth. His investigations into the nervous control of arteries in the living frog and bat no doubt led up to his work on inflammation and coagulation of the blood. When we remember that he also investigated pigmentation in the frog and the inhibitory action of visceral nerves, we realize how much he accomplished in the few years during which physiology claimed his attention, but by no means all his time, for he was then busily occupied in surgical work under Syme. There seems no reason to doubt that had he devoted his career to physiological research alone, his would have become one of the greatest names among the searchers out of the secrets of living structures. But this was never likely to follow, if Sir Charles Sherrington is right in thinking that all the time Lister's interest in physiology was really part of his interest in morbid processes and repair, in fact, in inflammation in its widest sense, to the study of which he afterwards devoted those qualities of insight, grasp of detail, and determination to see for himself—to take nothing on trust—which led him on to such beneficent success.

This success in the surgery of the human body has obscured some results of which Professor Sherrington reminds us. By showing the world how to get rid of suppuration in wounds intentionally inflicted he benefited physiology to an extent beyond calculation. When thereby experimental operations upon the lower animals could be undertaken with the assurance that they would heal aseptically, pain could be eliminated in such procedures, carried out, as they are in this country, under anaesthetics, for, as millions of human beings must have found, the healing of an aseptic wound is not painful. Not only has the brute and bird creation profited, but the physiologist is saved the pain and disappointment of seeing his experiments vitiated by suppuration and all its train of consequences. Pavlov's work on digestion, Ferrier's on the localization of cerebral function, and the discovery of insulin, with all that connotes, were only possible in the aseptic conditions which Lister introduced. Therefore, as Sir Charles Sherrington says, it is "with peculiar gratitude that the physiologist brings his tribute of admiration and veneration."

Professor Bulloch's discourse is of special interest, for not only is no man better qualified than he to estimate the value of Lister's work as a pathologist and bacteriologist, but he was closely associated with him for a dozen years in London. Few will gainsay his estimate of Lister, among all the distinguished men of our profession whom he has known, as *facile princeps medicorum*. In estimating Lister's achievements in pathology and in bacteriology, in which latter science he was a distinguished pioneer, it must be remembered that he had no well equipped laboratory with its instruments of precision at hand. His work was done in his study, and his instruments were largely devised by himself. His daylight hours were taken up by other work, and only in the evenings and far into the small hours of the morning could he work at his self-appointed tasks, in which he was cheerfully seconded by his devoted wife, who gave herself ungrudgingly to be his assistant and note-taker with an enthusiasm and patience which well became the daughter of James Syme. This work was undertaken, not only in search of new knowledge, but in order that he might speak to his class with first-hand knowledge of the facts he taught. The problem of the cause and process of coagulation of the blood was closely associated with that of the cause and manner of production of inflammation, for both of them

had to do with the production of suppuration. It is curious, as was remarked by Sir Rickman Godlee and others, that so acute an observer, whom little escaped, should have missed the phenomenon of diapedesis of leucocytes, which had been observed independently by two physiologists years before; their work was overlooked or forgotten till at last the process was described by Cohnheim. It is a somewhat remarkable fact that coagulation, which has been such a commonplace occurrence and has been studied for centuries, should still remain something of a mystery, so that, as Professor Bulloch tells us, it cannot now be said that we have materially advanced in a knowledge of its cause during the seventy years since the publication of Lister's work. It is always interesting to know of a great man's estimate of his own work. Professor Bulloch puts on record Lister's statement, made in 1905, that "If my works are read when I am gone, these" (on pigmentation of the frog and on inflammation) "will be the ones most highly thought of." Most of us will suspect he was mistaken, for his work on bacteriology was of great importance, and his "unsurpassed technique" enabled him to elucidate the problem of lactic acid fermentation. Yet he was not infallible, and when at Pasteur's suggestion he repeated an experiment in a different way and found his error, he freely acknowledged it, for, as he said, "Next to the promulgation of truth the best thing I can conceive that a man can do is the recantation of a published error."

In his address on Lister as a surgeon, Sir Berkeley Moynihan has enlarged on the parts which referred to Lister in [illegible] Hunterian Oration (BRITISH MEDICAL [illegible], 19th, 1927, p. 313). He recalls the state of things in the surgical world before Lister waved an enchanter's wand over the evil spirits of suppuration, pyaemia, and their train, and tells us how terrified Astley Cooper was lest erysipelas should attack George IV after the removal of an insignificant cyst from his scalp, and how helpless he was to prevent infection. This dread of erysipelas in such cases persisted long after Cooper's day. That distinguished surgeon Timothy Holmes, in his authoritative book on surgery,[1] solemnly warned his readers of the danger, related a dramatic story of a fatality, and even suggested the use of caustic instead of the knife when erysipelas was rife. It is a striking example of the backwardness of London surgeons in antisepsis that Mr. Holmes made no allusion to the method as useful in such a case, although the book was published six years after Lister left Glasgow. If such a leader as Holmes was thus blind, what could be expected of the average surgeon?

Sir Berkeley Moynihan emphasizes the important services which, owing to asepsis, surgery is now able to offer to pathology, substituting the living body for the cadaver in the mortuary. Lister, as he says, was as much the parent of asepsis as of antisepsis, if, indeed, they are really two methods. His great discovery was that of the part played by micro-organisms in the production of sepsis. Whether they are destroyed or their numbers are reduced to a negligible figure in the wound or in its immediate neighbourhood is a comparatively small detail. It is due to Lister that the great cavities of the human organism have been laid open to the surgeon and the gynaecologist, so that it is now hard to realize that only fifty years ago, in the year that he came to King's College Hospital, the governors of that institution had forbidden the staff to undertake ovariotomy. To-day the lay public recognizes the curative value of surgery, and Lister's work has brought even the dread and widespread scourge of cancer within the reach of cure by early and extensive operations, so planned as to include all diseased tissue and prevent recurrence.

There is no possibility of estimating the debt which mankind owes to Joseph Lister, and never has the Crown more truly interpreted the wishes of the nation than when it made him a peer.

[1] *Surgery: its Principles and Practice*, London, 1875, pp. 928.

DERMATOLOGY AT THE GENERAL INFIRMARY AT LEEDS.

THE development of the department for the treatment of affections of the skin at the General Infirmary at Leeds presents some points of interest, especially when viewed in connexion with the changes which have been decided upon by the board, and which include the appointment of a new honorary officer whose work will be confined to this department. When, in 1884, the appointment of assistant surgeons was followed by the appointment of assistant physicians, an informal arrangement was come to by the two newly appointed assistant physicians that the skin cases should gravitate to one and the throat cases should fall to the other. For many years the skin cases were thus seen along with the other out-patients on the days of one of the assistant officers. With the increase in the work it was found advisable to segregate the skin cases and to see them on a separate day, so that the honorary officer had three days of out-patient work, one being devoted to diseases of the skin. This plan has prevailed for about twenty-eight years, and under it the department has developed greatly, so that during the year ending December, 1926, 1,247 new cases were seen and the total attendance was 7,258. The board has now decided to appoint a physician in charge of the dermatological department. He will be required to have the qualifications necessary for a physician to the Infirmary, which are the possession of a degree in medicine of a university of the United Kingdom and either the Fellowship or Membership of the Royal College of Physicians of London. He will be placed in complete charge of the department, for which adequate accommodation is to be provided, and he will have placed at his disposal six beds for adults—three male and three female—and four cots, a total of ten to start with. In all probability the new officer will desire to see out-patients two days a week, and there is no doubt that the numbers mentioned above will tend greatly to increase, not only by the transfer of cases to a greater extent from the other departments of the Infirmary, but by an increase in the number presenting themselves for treatment at the institution. This is an almost invariable experience in connexion with similar developments of any department. The relation of the new department to the electro-therapeutic department and to the venereal department has been the subject of careful consideration. Arrangements have been made for the development of a self-contained electro-therapeutic department, so that the officer in charge may follow out the treatment of his cases without their leaving his immediate supervision, or may have them transferred to the general electro-therapeutic department. A similar arrangement is to prevail in the case of the relation with the venereal department. Facilities will also be provided for the officer to perform any operations he may desire, and he will have the services of one of the house-physicians to attend him at his ward visits and during his out-patient work. As the appointment of a special dermatologist is a new departure, the board has decided, not merely to advertise the appointment, but to put off doing so until there is reason to feel that there are one or more suitable candidates. Everyone in

connexion with the Infirmary is desirous of making the department a success, and any newcomer will be sure of a cordial welcome from his colleagues on the honorary staff.

THE CRISIS IN SHANGHAI.

THE following cable from Shanghai, received by the British Medical Association on March 31st, is, in its breathless telegraphese, more eloquent than any paraphrase or extension:

> British Medical Profession here requests your help persuade Government give no consideration Chinese assurances protect British lives property. Nationalist Army violently anti-foreign and when victorious becomes organized for plunder murder. Nationalist leaders swollenheaded by unresisted victories over Northern Army and by easy possession British concessions and property without struggle. Negotiations present time futile dangerous. Any concession regarded as signs weakness fear. Cold-blooded murder Doctor Smith Nanking and violence to women confirm opinion previously universal our only safeguard protection Navy Army against similar atrocities here.

This leaves no doubt that our brethren in Shanghai have thoroughly approved the action of the British Government in ordering out a brigade of infantry and ancillary units to reinforce the Shanghai Defence Force. In the ancillary units are included an R.A.M.C. company, a hygiene section, a sanitary section, medical mechanical transport, and a vast medical depot unit. The telegram was communicated to the press and sent at once to the Foreign Office, and the Council on April 5th directed that a telegram be sent to the profession in Shanghai informing them of the cordial sympathy of the Association and telling them what had been done.

IMPRISONMENT IN 1925-26.

THE annual report of the Prison Commissioners for 1925-26[1] contains matter of great interest in every page. Naturally certain parts—Section XIII, and Appendix No. 1, being the report of the Medical Commissioner, Dr. G. B. Griffiths, and Appendix No. 2, containing extracts from the annual reports of prison medical officers—which deal with the great problem presented by the law-breaker from the medical point of view, engage our first interest. Dr. Griffiths well describes a prison as it ought to be as "a place for hard work, discipline, and education with a view to rehabilitation on completion of sentence." When this ideal has been realized, as in time it will be, the problem must remain largely psychological as well as sociological; but to-day, as a perusal of this report shows, a considerable part still belongs to the domain of abnormal psychology. To this we return below, but first must glance at the size of the problem as revealed by official statistics. The total number of prisoners received under sentence during the year was 54,737. Truly a great number, but less by 882 than the receptions during the previous twelve months. This total, of course, does not represent the number of persons concerned, many of whom were convicted and imprisoned more than once during the year; thus, on analysis the total number of 42,844 receptions on conviction during the year represented actually 34,396 persons, the balance being caused by the repeated convictions of 6,455 persons. Nevertheless, it is gratifying to note that the decrease recorded in last year's report is continued in this, though at lessened rate. The comparative figures for the past quarter of a century, given in tabular form, are striking. The average yearly total receptions on conviction for the quinquennium ended 1903-4 amounted to 167,100; rose to 186,569 during the next five-year period; and in the five years immediately preceding the war numbered 158,782. An abrupt fall to an average of 53,068 marked the years of warfare (covered by the five years ended 1918-19), and since 1924 there has been a yearly decrease to the present figure. The Commissioners furnish a tabular comparison of the principal offences in respect of which prisoners were received in the last pre-war year, 1914, and the year under review, which shows the following remarkable decreases: Murder, manslaughter, wounding, etc., fell from 474 to 448; burglary, housebreaking, etc., from 1,960 to 1,685; larceny, embezzlement, receiving, etc., from 19,126 to 11,277; assaults from 8,666 to 3,087; drunkenness, etc., from 51,851 to 10,698; breach of police regulations from 8,661 to 1,757; prostitution from 7,952 to 1,060; and begging and sleeping out from 15,019 to 2,714; that is, the annual receptions into prisons for indictable offences have fallen since the last pre-war year from 21,560 to 13,410, and for non-indictable offences from 82,149 to 19,343. The Commissioners consider that the effects of probation, allowance of time in which to pay fines, and the operation of the Mental Deficiency Act have been the chief factors in this progressive diminution, but that industrial training during imprisonment and the increased efficiency of the agencies for the assistance of prisoners on discharge have had their effect. Of the whole number received on conviction during the year, 22,988, or 66 per cent. of the men, and 6,840, or 86 per cent. of the women, had been previously convicted, and of these 9,200 of the men and 4,583 of the women six or more times. It is again gratifying to compare these numbers with the year 1913-14, when no fewer than 28,000 men and 15,000 women had incurred six or more previous convictions. Even though the Commissioners are careful to point out that as these figures do not deal with the whole mass of recidivism in prison their value is limited, and also bearing in mind that they must be correlated with the great numbers of offenders otherwise dealt with, there seems to be room for the hopeful inference that, on the whole, we are steadily becoming a more law-abiding nation. The hope for the future lies in the increasing development of preventive measures and the treatment of the young offender. In this connexion two of many highly important matters discussed in this report may be mentioned. The first is the short sentence, which, the Commissioners again say, remains an outstanding defect in our penal system. "There is no doubt," they say, "but that the prospect of prison has a strong deterrent effect on those who have never yet passed its gates; nor that, once the disgrace of imprisonment has been incurred, much of that effect has been lost"; whilst the medical officer of Lincoln Prison says that the mere fact of committal to prison brings about a complete revolution in orientation, morally bad. The most hopeful prospect, the Commissioners say, lies in the development of the probation system, by which a point may be reached when many offenders can be so well supervised "in the open" that if they fail a period of custodial training of substantial length will be justified. The second point concerns a matter of high importance and much difficulty—the proper treatment of the mentally defective delinquent. Dr. Griffiths, in his report, refers to the application of the Mental Deficiency Act as having resulted in the permanent diminution of the prison population by a large but unknown number—possibly 200 daily; but there remains a large contingent of weak-minded habitual petty offenders who cannot be certified under the Act as it stands at present, who are unsuitably treated in prison, and who unfavourably affect the discipline, work, and training of their fellow prisoners. Medical officer after medical officer, writing with long experience of this unfortunate class of prisoner, urges the need for special provision, with due safeguards, of the indeterminate detention under non-penal conditions of these at present uncertifiable feeble-minded

[1] Report of the Commissioners of Prisons and the Directors of Convict Prisons for the year 1925-26. H.M. Stationery Office. (Pp. 83. Price 1s. 6d. net.)

offenders. To send them to the workhouse is futile, says one medical officer, and the medical officer of Holloway Prison says that if provision were made for these uncertifiable cases a large part of that establishment might be closed. They include large numbers in which the existence of mental deficiency "from an early age" cannot be proved or maintained; also cases of epilepsy and encephalitis lethargica. The need is obvious and pressing, the remedy equally obvious, and it is greatly to be hoped that if the Mental Deficiency Bill, recently introduced, becomes law, it will be found to permit the continued care and control, in non-penal institutions and colonies, of the defective prisoner who cannot be certified to-day, and whose life, spent largely between prison, workhouse, and a doubtful freedom, is a long punishment to himself, a trial to his friends and fellows, and a burden to society.

FRENCH NATIVE SCHOOLS OF MEDICINE.

THE shortage of European medical men in the oversea possessions of France has prompted the Government of that country to organize, in the colonies themselves, a staff of native assistants who are intended primarily to practise medicine among the native population. Their training for these duties is provided in native schools of medicine, of which Pondicherry, geographically situated in the presidency of Madras, is the oldest. This school confers a diploma of native health officer, which is described as equivalent to those granted by the medical schools of Madras, Calcutta, and Bombay. The number of medical students who have attended the courses since 1863 is 110, and the number of diplomas granted 65. Of the young diplomates some go into private practice; others enter the colonial service. It is now proposed to utilize them also for medical work in the French settlements of Oceania. Inoculation students and student midwives are also trained. The former are useful as vaccinators; the latter encounter some difficulty owing to questions of caste, and also because they refuse to practise abortion, but they are nevertheless making headway. The native school at Hanoi in Tongking dates from 1902. Its first head was Dr. Yersin, the discoverer of the plague bacillus. Its medical students are drawn from all the countries which constitute Indo-China. In the session of 1923-24 those who enrolled for the five years' course numbered 91. The Madagascar school is at Antananarivo. Its course is of four years' duration, preceded by two years of preliminary study. Its students are mostly Hovas. Up to 1920 diplomas as native assistant doctors had been granted to 336 students. Four diplomates have since qualified in medicine at Montpellier. One was sent to Paris to study dental surgery, and is now in practice as a dentist at Antananarivo; 208 diplomas have been issued to native midwives. The West African school is at Dakar. Its head is assisted by an advisory council presided over by the Inspector-General of Public Health. At present it has 40 students of medicine, 6 of pharmacy, 11 veterinary students, and 41 student midwives. They are drawn from Dahomey, the French Sudan, Senegal, Guinea, and the Ivory Coast. Liberians may attend, but are classed as aliens. This school is associated with an Institute of Social Health, and with the Dakar Institute of Biology, at which important work on tropical diseases is being carried on. Besides these four schools of medicine proper, subsidiary educational centres have been set up at Guadeloupe in the West Indies for midwives, and at Réunion near Madagascar for pharmacists. This record of the French native medical schools, set forth in a recent paper by the League of Nations, is one of considerable interest. Their finished product, the native health officer, though he cannot possess the experience and attainments of the graduate educated in Europe, fills nevertheless a useful place in the field of medical service. In some respects, indeed, he has special opportunities. His acquaintance with the customs and languages of the people may enable him to cope with age-long prejudices which bar the way to the European, and to diffuse some knowledge of hygienic methods of living among those with whom he has to deal. In British India, as in the French colonies, native medical assistants have done good work.

HISTORY OF THE MAYO CLINIC.

THE Mayo Clinic has been visited by so many British medical men, and is so universally known, that the *Sketch of the History of the Mayo Clinic and the Mayo Foundation*[1] will be widely welcomed. The biographical account of the Mayo family shows that it includes John Mayow (1643-1679) of Oxford, the famous physiological chemist. William Worrell Mayo (1819-1911), the father of the present famous surgeons, was born near Manchester and educated at Owens College, being a pupil of John Dalton. In 1845 he went to New York as a chemist, and, after graduating in medicine in 1854, settled the following year in Minnesota, and in 1863 moved to Rochester. A destructive cyclone in 1883 led to the establishment of a hospital, of which Dr. W. W. Mayo was in charge. Out of this grew the Mayo Clinic, which until 1900 was surgical; then Dr. H. S. Plummer organized the medical service and the *x*-ray department, and in 1905 Dr. L. B. Wilson became pathologist, and the special departments came into existence later. The figures of operations—495 in the year 1893, as compared with 23,628 in 1924—show the phenomenal growth of the activities of the famous clinic. There is a list of the medical men bearing office in the clinic. The establishment of the Mayo Foundation for Medical Education and Research and its affiliation with the University of Minnesota in 1915, which eventually involved the gift, "unique in the annals of American education," by W. and C. H. Mayo, greatly increased the facilities for graduate medical education. In 1920 the Mayo Properties Association was incorporated with the object of facilitating the use of the properties of the Mayo Clinic, which is described as "a medical democracy composed of the members of the permanent professional staff, each of whom has a vote in the management of its affairs." It is noteworthy that surplus earnings are pledged to the support of the educational and research work.

SCIENTIFIC AND INDUSTRIAL RESEARCH.

THE report of the Committee of the Privy Council for Scientific and Industrial Research for the year 1925-26[2] shows that, even in these days of economy, the Government cannot be accused of failing to support research. Estimates for expenditure, which in 1923-24 amounted to £276,863, have reached £442,877 for 1926-27. At the same time, the committee does not seem quite satisfied with the results of its efforts. It finds "some evidence that British industry has not hitherto paid sufficient attention to the need for the same accuracy of scientific control and the same spirit of research" in utilizing the results of scientific inquiries in industrial production "as are expected in the laboratory. . . . The nation will not gain anything if the department publishes the results of industrial research which our friendly foreign competitors are in a better position to take advantage of than British industry." The department wisely sets out to stimulate rather than to displace private enterprise, and to promote research which

[1] *Sketch of the History of the Mayo Clinic and the Mayo Foundation.* From the Division of Publications, Mayo Clinic. Philadelphia and London: W. B. Saunders Company. 1926. (Med. 8vo, pp. x + 185; 16 illustrations, 19 charts. Price 16s.)

[2] Cmd. 2782. London: H.M. Stationery Office, 1927. 3s. net.

is practical in aim. It encourages the formation of research associations, and gives grants both to such associations and to individual workers. During the past year a research association for the preserved food industry has been formed, to work in close co-operation with the Research Association for the Cocoa, Chocolate, Sugar Confectionery, and Jam Trades. The Advisory Council of the department is of opinion that in pure science too many men are encouraged to specialize in chemistry. Of the 700 students to whom maintenance allowances have been given during the last seven years, nearly 400 were students of chemistry. The biological sciences, on the other hand, are short of investigators; and the demand for men who combine chemistry with such subjects as agriculture, biochemistry, and botany exceeds the supply. At the same time, there is little or no sign at present of atrophy of the brain of the country in pure science. In applied science the Advisory Council finds that many prominent industrial firms are rapidly developing scientific organizations; but that in the interests of the country far greater expansion is necessary, and far greater co-ordination of effort. It is thought that these aims should be achieved either by the formation of large industrial combines or by the encouragement of co-operative research amongst small independent firms. The Advisory Council holds the opinion that in certain matters research on a national basis is necessary. Thus it welcomes the recent rapid expansion of scientific research by the service departments. In other types of research the results are not only of importance to the manufacturer and the user, but are also essential to the progress of pure science. These researches, it is said, cannot be left to private initiative. They include the maintenance and improvement of standards and methods of measurement; the determination of the fundamental properties of materials, such as iron, steel, alloys, and lubricating oils; the protective qualities of materials for the safety of *x*-ray workers; the thermal properties of non-conducting materials for refrigerating plant. Finally, the department deals with researches into such matters as fuel, forest products, building construction, and the preservation and transport of foodstuffs.

PRINCIPLES UNDERLYING TUBERCULOSIS SCHEMES.

THE County Councils Association recently adopted certain resolutions with regard to the principles on which schemes of local authorities for the treatment of tuberculosis should be conducted, and a circular (No. 771) was issued by the Ministry of Health on March 31st giving the Minister's views on the various points. The circular is addressed to county boroughs, county borough councils, and tuberculosis joint committees in England. The primary duties of tuberculosis officers should, it is stated, be diagnosis, consultations with general practitioners, search for and examination of "contacts," general supervision of patients who do not require active treatment, "following up" of those who cease attendance, advisory assistance in after-care, and education of the general public. Actual treatment should be limited to patients whose treatment requires special knowledge or technical skill, and to those who are unable to obtain adequate medical attendance. The giving of medicines and cod-liver oil should be discouraged; and stress is laid in the circular on teaching patients to value advice and hygienic instruction instead of relying on drugs. Extra nourishment should not be given to those who can pay for it themselves, or to those who should be dealt with by the machinery of the Poor Law. In the Minister's opinion, the patients most suitable for extra nourishment are those who have had adequate sanatorium treatment and, with additional food, may be expected to recover full working capacity, and those waiting for admission to sanatorium treatment in whom arrest of the disease may reasonably be anticipated. While residential treatment for a short time is frequently of value in restoring working capacity to patients with slowly progressive pulmonary tuberculosis, the Minister of Health has been advised that much importance should be attached to the provision of residential treatment for advanced and acute cases. Local authorities are reminded of their compulsory powers under Section 62 of the Public Health Act, 1925, for the removal from their homes of infectious cases of pulmonary tuberculosis. They are advised also to combine the institutional treatment of surgical tuberculosis with the treatment of crippling by other diseases in children from child welfare authorities and local education authorities, in an orthopaedic hospital which may serve the areas of several authorities. Children suspected of definite tuberculosis should only be admitted to sanatoriums for a brief period of observation with a view to the establishment of a definite diagnosis. "Pre-tuberculous" children should be left to the care of the local education authorities. The points in the circular of chief interest to the medical profession are, perhaps, the emphasis laid on residential treatment for advanced cases, and the procedures mentioned as special treatment. Both points illustrate the prevailing haziness in methods of dealing with the disease. The sanatorium superintendent is anxious to fill his institution with very early cases and to show a high percentage of cures. The Minister of Health wishes to segregate late cases to prevent infection. In either case the cost of institutional treatment is prohibitive so far as dealing with all the patients in either category in this country is concerned. As for the special treatment by tuberculin, the circular gives no indication for what cases it is used, with what object in view, how far its use is general, and under what method of dosage it is given. And we are unaware of any authoritative pronouncement on these matters from any other source.

THE BRITISH INSTITUTE OF PHILOSOPHICAL STUDIES.

THE elucidation of many problems requires a careful study of underlying principles, and speculation often paves the way for new discoveries. Both considerations are admittedly important in the advance of medical science, and therefore the letter on page 699 commending the aims of the British Institute of Philosophical Studies will have a special interest for medical practitioners. It was founded in London to bring leading exponents of the various branches of philosophy into closer contact with the general public, so that obscure issues in human life might be subjected to comprehensive consideration. Courses of lectures are delivered, tutorial classes are arranged, a quarterly philosophical journal is published, and research is encouraged. During the present session (1926-27) among the subjects under consideration are various philosophical questions, such as the relation of mind and matter; the development of philosophy since Kant; psychology, including its application to medicine, industry, and education; the world of values; and the philosophies of social life and religion. Each lecture is followed by discussion for one hour. The importance of the comprehensive view in the solution of a difficult problem needs no emphasizing at this moment, when the world is recalling with gratitude the services rendered by Lister, who by studying the process of fermentation revolutionized the practice of surgery. The medical practitioner and the student of natural philosophy are so closely akin that the present opportunity for co-operation in study cannot fail to be welcome to many; it may well prove to be fruitful in new discoveries.

THE LISTER CENTENARY CELEBRATIONS IN GLASGOW.

THE celebrations of the centenary of Lord Lister's birth, which were held at Glasgow on April 1st, were not unworthy of that great surgeon whose memory they were designed to honour, or of the town which had the singular good fortune to be the scene of his momentous discoveries. The city of Glasgow, which had already in 1908 expressed its appreciation of Lord Lister by conferring its freedom upon him, the University of Glasgow which he served with such distinction for nine eventful years, the Royal Infirmary in the wards of which his great work began, and the Established Church of the land which he adopted for a time, united with representatives of other Scottish universities, hospitals, and medical schools, with scientific and medical associations of high repute, great commercial trusts and corporations, and men of note in various departments of activity, to play their respective parts in a stately ceremonial which was aided by weather of tempered brightness appropriate to the occasion. A mild sun, warm enough to comfort, and a light breeze, sufficiently cool to promote heat-loss and stimulate metabolism, seemed to fit in well with Lord Lister's gentle spirit and keen creative mind. The season of spring, with the round of the year beginning afresh and life stirring visibly in the trees by the University where his statue is set, was aptly symbolical of his benign genius, from which, it may be said, in the world of surgery,

Magnus ab integro saeclorum nascitur ordo.

COMMEMORATIVE SERVICE IN THE CATHEDRAL.

The celebrations began with a public commemorative service held in the Cathedral of Glasgow. The representatives of public bodies assembled at 10.45 a.m., in the spacious Pathological Department of the Glasgow Royal Infirmary, and walked thence in processional order through the Infirmary by way of the South Gate to the Cathedral.

In advance of the procession went the Halberdiers of the City, followed by the Right Rev. J. D. McCallum, D.D., Moderator of the Church of Scotland, the Rev. W. M. Clow, D.D., Principal of the United Free Church College of Glasgow, and the Rev. Lauchlan MacLean Watt, D.D., Minister of Glasgow. Next came the civic mace of Glasgow and the mace of Glasgow University.

The procession in chief was headed jointly by Mr. David Mason, Lord Provost of Glasgow, and Sir Donald MacAlister, Bt., K.C.B., Principal and Vice-Chancellor of the University.

Following the Lord Provost were the Deputy Chairman of the Corporation, Councillor Stark Brown, and representative magistrates, including Bailies Mrs. Bell, Gillespie, Mrs. Barbour, Dunlop, and Archibald. Following the Principal came Sir Hector Cameron and the Court and Senate of the University. The Court was represented by Dr. David Murray, Mr. William Brodie, Dr. J. Bruce Murray, and Professor T. H. Bryce. Among members of the Senate present were Professors R. Muir (Pathology), J. Graham Kerr (Zoology), J. H. Teacher (Pathology), T. K. Monro (Medicine), W. K. Hunter [illegible] urgery), P. Paterson (Surgery), E. T. [illegible] Cormack (Engineering), and J. R. C [illegible]

Sir Thomas Paxton and Sir W. M. Montgomery attended as ex-Lord Provosts. The Royal Faculty of Physicians and Surgeons of Glasgow, represented by Dr. R. M. Buchanan (President), Mr. G. H. Edington, Dr. Freeland Fergus, and Dr. James Adams, came next in order, succeeded by the overseas delegates, including Emeritus Professor Irving H. Cameron of Toronto and Professor F. de Quervain of Lausanne. The University of St. Andrews was represented by Professor F. J. Charteris, Edinburgh University by Professors J. Lorrain Smith and John Fraser, and the University of Aberdeen by Professor Ashley Mackintosh. Professor G. M. Robertson attended as President of the Royal College of Physicians of Edinburgh, and Dr. A. Logan Turner as President of the Royal College of Surgeons of Edinburgh.

To these succeeded the delegates of the Royal Technical College of Glasgow, the Faculty of Procurators, the Institute of Accountants and Actuaries, the Clyde Navigation Trust, the Merchants' House, the Trades House, the Chamber of Commerce, the Glasgow Parish Council, the Glasgow Education Authority, and the Royal Philosophical Society of Glasgow. Among the representatives of the press was Sir Robert Bruce of the *Glasgow Herald*.

Governors and officials of the great Glasgow hospitals came next. The Glasgow Royal Infirmary was represented by Dr. James Macfarlane, chairman, and Dr. Ian Grant; the Western Infirmary by Colonel J. A. Roxburgh, V.D., D.L., LL.D., and Colonel D. J. Mackintosh, C.B., M.V.O.; the Victoria Infirmary by Mr. William Gray, chairman; the Royal Samaritan Hospital for Women by Dr. J. Nigel Stark; the Royal Maternity Hospital by Mr. James Thomson, director; the Royal Hospital for Sick Children by Professor L. Findlay; the Glasgow Eye Infirmary by Dr. A. J. Ballantyne; and the Ear, Nose, and Throat Hospital by Dr. J. Galbraith Connal.

The hospitals were succeeded by representatives of the extramural schools of medicine in Glasgow, the Anderson College and St. Mungo's College; these were followed in their turn by the Glasgow Royal Medico-Chirurgical Society, the University Medico-Chirurgical Society, the Presidents of the Students' Representative Council, the University Union, and the University Athletic Club, and representatives of the principal medical societies in Glasgow, including Dr. W. D. Macfarlane for the Obstetrical and Gynaecological Society.

The British Medical Association was represented by Dr. George A. Allan, F.R.F.P.S.G., a member of the Central Council of the Association, and the Glasgow and West of Scotland Branch of the Association by Dr. J. P. Brown, D.S.O., President, Dr. Hill, President-Elect, and Dr. J. G. McCutcheon, Secretary.

Among others who participated in the day's proceedings were Sir John Bland-Sutton, Bt., Past President of the Royal College of Surgeons of England; Emeritus Professor Murdoch Cameron of the University of Glasgow; Mr. A. E. Maylard, lately surgeon to the Victoria Infirmary; Dr. A. S. M. Macgregor, Medical Officer of Health for Glasgow; Dr. A. K. Chalmers, lately Medical Officer; Colonel T. Kay, D.S.O., representing the Royal Army Medical Corps; Sheriff Principal A. O. M. Mackenzie; Sir John S. Samuel, K.B.E.; Sir Frederick Gardiner, K.B.E.; Sir Charles Cleland, K.B.E.; and Sir D. M. Stevenson.

The service in the Cathedral, which began at 11.15, was conducted by Dr. MacLean Watt, assisted by Dr. McCallum and Principal Clow. The congregation, in prayer, thanked God for His servant Joseph Lister, commemorating now his labours.

THE CIVIC LUNCHEON.

At one o'clock the Lord Provost and Corporation of Glasgow entertained a party of 350 persons to luncheon in the City Chambers.

Sir JOHN BLAND-SUTTON, Bt., proposed the illustrious memory of Lord Lister. He recalled that in the course of the Latin war when Aeneas was wounded in the thigh the physician Iapyx, after extracting the missile, instilled into the wound a tincture, prepared from dittany and rendered potent by Venus, which stanched the blood, relieved the pain, and restored the hero to vigour. In 1866 a patient was admitted into the Glasgow Royal Infirmary with a compound fracture of the leg. The Professor of Surgery, Joseph Lister, adopted the principles of Iapyx, but instead of tincture of dittany he instilled into the wound a solution of crude carbolic acid. The issue was successful, and it was of much importance, for it laid the foundations of the glorious edifice of antiseptic surgery. The treatment adopted by Lister in that instance was no sudden inspiration. Confronted with the endemic post-operative sepsis of these times he had come to the conclusion that infection was derived from instruments, sponges, and fingers, and had selected carbolic acid for the purpose of destroying the morbific agents. Pasteur's demonstration that putrefaction was caused by the growth of microbes in putrescible substances was a welcome confirmation of his views. As Pasteur revolutionized the winepress and the brewery, so Lister transformed the methods of operative surgery. Antisepsis in due season developed into asepsis, and the surgical shambles of 1860 were now replaced by operating rooms of spotless purity, where all concerned were clothed from nose-tip to toe-tip in sterilized linen garments, and the theatrical silence was only broken by the rhythmical breathing of the patient or an occasional utterance from a nervous operator. The end, however, was not yet. Surgery must now proceed to cure morbid growths by chemotherapy and physical agents, and

there were clear signs of the dawn of such an era. Be that as it may, Lord Lister had had the rare privilege of living to see his principles adopted by surgeons throughout the world. The bronze statue in Kelvingrove Park exemplified his steadfastness in the pursuit of truth. It was an expressive tribute to the great surgeon whose influence would remain as long as surgery was practised as an art, and the conquest of sepsis would continue to be a blessing on every race of mankind.

The toast was honoured in silence.

Dr. A. LOGAN TURNER, President of the Royal College of Surgeons of Edinburgh, proposed the toast of the Medical School of Glasgow. He said that during the two hundred years which had elapsed since the Glasgow and Edinburgh medical schools were founded there had been a number of happy interchanges of personnel, thus forging links of mutual benefit. Yet the closest bond of union was formed in the person of him whose ineffaceable memory they were met to do homage to. The same spirit which in the industrial world had given to Glasgow such proud distinction had conferred upon her medical school a foremost place in the development of medical services.

Principal Sir DONALD MACALISTER, who replied, said that he was bred to the medical profession in Cambridge and London and not in Glasgow, and so could view the medical school of Glasgow from a comparatively detached standpoint. The almost unbiased verdict was that the Glasgow school was not inferior to any in the country. With ten or eleven clinical hospitals, voluntary and municipal, at its disposal for clinical instruction, it was in that respect perhaps superior to any. Every year added to its resources in equipment and in staff, thanks to the liberality and generous devotion of Glasgow's citizens. Its motto was "Science with practice." Pasteur's science, combined with Lister's practice, had transformed the surgery of the world. The Royal Infirmary was fully re-established as a clinical school of the first order, and all mankind was united in acclaiming the birthday of the benefactor whose untiring devotion to the improvement of the surgical practice of his time, and whose unfaltering faith in science as a foundation, made the medical school of Glasgow the seed-bed of a mighty harvest for the healing of the nations.

Dr. R. M. BUCHANAN, President of the Royal Faculty of Physicians and Surgeons of Glasgow, proposed the toast of the Corporation of Glasgow. He referred to the part played by the magistrates and corporation of Glasgow in facing the great epidemic scourges of other days, now happily under control. The beds for infectious disease in Glasgow now were ten times the number available in Lister's time. Lister in his work observed three principles: prevention of infection, elimination of infection, should it occur, and the maintenance of the non-infected state. These same principles were applied by the corporation in the field of public health, and he expressed the hope that the results of their efforts would at no distant date be as substantial as those achieved by Lord Lister.

The LORD PROVOST, in reply, said that it was fitting that the corporation should honour the memory of Lord Lister, whose wonderful experiments, carried on in the city, had ripened into a glorious success.

THE LISTER STATUE IN KELVINGROVE PARK, GLASGOW.

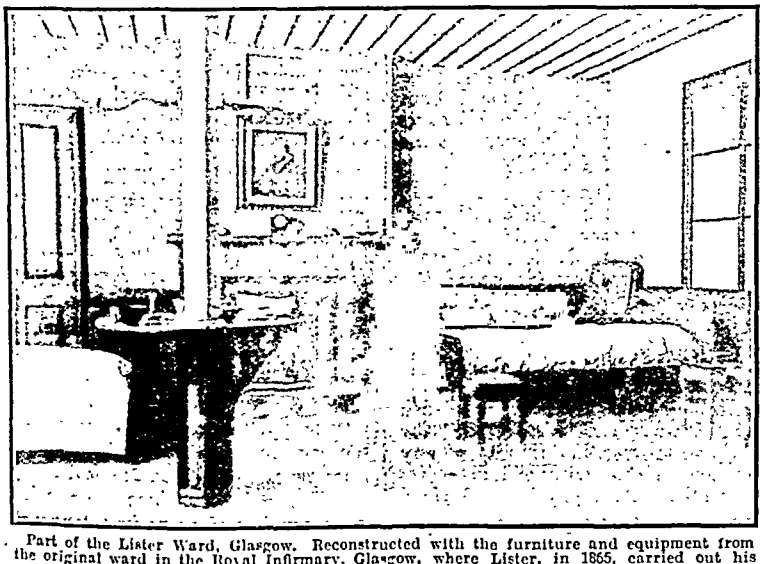
CEREMONY IN KELVINGROVE PARK.

After the luncheon there was an impressive ceremony at Lord Lister's statue, an imposing seated figure on a granite pedestal, placed in Kelvingrove Park near the right bank of the River Kelvin. The rising ground behind the statue is crowned with a fringe of trees which showed a faint veil of green. Beyond the trees the high tower of the University looked down on the memorial of her world-famed teacher. The representatives of various bodies paying homage to Lord Lister's memory took up their position in front of the statue. The Lord Provost placed a wreath at the base of the statue on behalf of the corporation and citizens. Sir Donald MacAlister performed a similar office in the name of the University of Glasgow; and other wreaths were placed in position by representatives of the Royal Faculty of Physicians and Surgeons of Glasgow, the Royal Army Medical Corps, the Royal College of Surgeons of Edinburgh, the British Medical Association, the Royal Infirmary of Glasgow, the Faculty of Procurators of Glasgow, and the Royal Philosophical Society of Glasgow.

RECEPTION AT THE UNIVERSITY.

At 8.30 p.m. a reception was held in the Bute Hall of the University. The occasion was remarkable for its personal links with the memory and work of the master. Short addresses were delivered by Sir Donald MacAlister, Bt., K.C.B., Principal of the University; Sir Hector Cameron, C.B.E., sometime Lord Lister's house-surgeon in Glasgow; Sir George Beatson, K.C.B., sometime his house-surgeon in Edinburgh; Professor Irving H. Cameron, Toronto; Emeritus Professor Murdoch Cameron, sometime Lord Lister's dresser in Glasgow; and Professor Archibald Young, the Regius Professor of Surgery.

Sir DONALD MACALISTER said:



It is my privilege, in the name of the whole University, to offer a grateful welcome to the guests who to-night join with us, Lister's contemporaries and Lister's heirs, in celebrating his hundredth birthday, and, in common with the whole world, offering our tribute of blessing and honour to his venerated name. By four days we anticipate his actual centenary, but I do not apologize for that. It is fitting that Glasgow, which saw the first beginnings of his beneficent labours in the Regius Chair of Surgery and in the wards of the Royal Infirmary, should give a lead to other cities and universities in voicing his praise.

Here he sowed the rich harvest which all mankind has reaped and is still reaping. Here, in ground that was not without its storms and stones, he planted in faith the seed which has multiplied a hundredfold in every region of the earth where the art of healing is practised with knowledge. Here he elaborated with patience, and with conviction that his foundations were well and truly laid on the bedrock of scientific truth, the method of treatment which transformed surgery from a perilous adventure into a safe and saving intervention in aid of *vis medicatrix naturae*.

And note that Lister's innovation did much more than

ensure the clean healing of such wounds as accident or the merciful knife inflicted under the limitations to which surgery was then subject. He dispelled what were regarded as the inevitable dangers, not of the operating table, but of the ward set apart for recovery. He wrought hope of healing to old regions that were too often but valleys of the shadow of death. But, in addition, he opened up, like a surgical Columbus, whole continents for surgical exploration and life-saving endeavour. The surgeons of his day knew well that in the brain, in the abdominal cavity, in the limbs and joints, the seeds of death and disablement were lurking, and in due time would bear their fatal fruit. If only these weeds could be extirpated in time, life and health might still be saved. But to the pre-Listerian operator these regions were barred as by a flaming sword—the deadly sword of septic inflammation. The needful operation might be dared in half despair, but none was so bold as to promise either to himself or to his patient that recovery would ensue. Lister turned aside and quenched the flaming sword, and to-day the village doctor in the cottage home, the ship surgeon in a tossing cabin, can venture into the arcana of our frame with hope and confidence, and snatch a life from the very jaws of death.

In the weeks to come the work of Lister will be rehearsed in many lands and in many tongues. Of our guests here many will proceed to other centres to take part in these commemorative festivals, whose testimony will be borne to the vast sweep of Lister's discoveries and their influence on the relief of human suffering. These guests and delegates will be able, by reason of their own slightly ante-natal commemoration, there to testify also that in Glasgow, where Lister's revolution was cradled, the inheritors of his teaching were the first to raise the chorus of thanksgiving and veneration in this centennial year; that here, in the city of which he was a freeman and in the University in which he first held a professorial chair, his name and fame are cherished with pride and enthusiastic gratitude.

Part of the Lister Ward, Glasgow. Reconstructed with the furniture and equipment from the original ward in the Royal Infirmary, Glasgow, where Lister, in 1865, carried out his researches and first put into practice his antiseptic principles. (Wellcome Historical Medical Museum copyright.)

In the halls of the University of Glasgow are set up the memorial images of the benefactors of mankind and of human civilization whereof we make our special boast—Adam Smith, James Watt, Lord Kelvin, Lord Lister, these four: but the greatest of these, for us here and now, is Lord Lister.

Sir HECTOR CAMERON, Lord Lister's beloved disciple, who quoted from Ecclesiasticus, "Let us now praise famous men," asked what there had been in Lister's life-work and its consequences to warrant such a universal and unanimous acclaim. Had he added to the armamentarium of surgery or to its usefulness as a beneficent art? Yes, but many others had done the same. Was he a more deft operator than others? Many, he believed, were more skilful exhibitors of what he might call surgical carpentry. The reason was that by his genius he had introduced an absolutely new era of surgery, changing its character from the very bottom upwards. When, many years ago, a great French surgeon, Dr. Lucas-Championnière, stated that there were only two eras in surgery, that before Lister and that after him, everyone recognized the truth of the pronouncement. He accomplished that which all the centuries that preceded him had failed to do. Lucas-Championnière came to Glasgow in 1868 when a very young man, when Sir Hector was house-surgeon to Lister. He later became a surgeon of the old Hôtel-Dieu, and succeeded in changing the character of his wards by banishing sepsis from them. Another youthful visitor who came to Glasgow in 1869 was Dr. Warren Collins of Boston, who about two years ago wrote him of his contact with Listerian principles that "after studying medicine and surgery at the great sources for three years he had been confronted with a new doctrine which necessitated a complete revision of medical science. It had been, as it were, like suddenly stepping out through a door from an old era into a new one." Thus was the revolution seen at an early period, and recognized almost at sight, by two particularly well educated young foreigners. Since those days great progress had been made, until now the avoidance of sepsis and its consequences in all wounds was a matter fully understood by every surgeon. No human mind, however, could compute the pains which had been relieved, the lives which had been saved, or the tears which had been averted. Lister had studied sepsis before 1860, during the currency of Liebig's view which implicated the oxygen of the air. This hypothesis he could not accept, but Pasteur's researches suggested to his mind the likelihood of a microbic origin. Pasteur furnished him with the scientific clue, following which he instituted the methods of treatment which have made his name renowned. But, as Clifford Allbutt had observed, "he saw the importance of Pasteur's work because he was watching on the heights, and watching there alone." Lister reposed a steady confidence in the mind of youth. In his hours of trial, when surrounded by hostility, he felt sure that his students would carry on his principles. "I have always," he used to say, "had youth on my side." When God smote him he threw his torch to the youth of the world. The problem of cancer awaited solution. It was for youth to assail it. As they followed the quest let them emulate Lister in his truthfulness, modesty, avoidance of contention, perseverance, and patience.

Sir GEORGE T. BEATSON said that when Lister went to Edinburgh from Glasgow in 1869 he had three objects in view. The first was to perfect a simple and efficient dressing; the second, to enlarge the field of operative surgery; and the third, to convince the medical profession that his antiseptic system was sound. He found his surgical colleagues in Edinburgh as sceptical as those whom he had left behind. The *odium medicum* against him was strong among the wise men of the east, and one professor dismissed his claims with the comment that his work would be found unreliable, as he was swayed by the bias of a fixed theoretical preconception. In 1871, 1872, and 1873 Sir George worked under Lister as his dresser, clerk, and house-surgeon. He saw the gauze absorbent dressing and was familiar with the carbolized spray. Henley was in the wards during his term of office. He had lost one foot from tuberculosis and the other had been condemned. Lister operated with success, and the grateful patient enshrined his benefactor in his vivid and well known verses. Sir George Beatson recalled Lister's unflinching courage, his enthusiasm, his modesty, his unruffled temper, and his handsome, thought-lined face. He appeared to stand,

like Aaron, between the dead and the living. Through his great work the art of surgery entered on a new career.

Dr. IRVING H. CAMERON, Emeritus Professor of Surgery at the University of Toronto, stated that while his seniors had scouted antisepsis he himself had been one of its early supporters. He referred to the two visits paid by Lord Lister to Canada and the United States. He quoted a number of interesting extracts relating to Lord Lister from a Canadian medical journal.

Emeritus Professor MURDOCH CAMERON, who had been one of Lister's dressers in the Glasgow Royal Infirmary in 1867-69, described in picturesque terms the internal conditions and surroundings of the Infirmary at that time. He spoke of the ravages of typhus fever, and of knives handed direct from the sharpening stone to the surgeon. He recalled, he said, with special pleasure a letter which he had received from Lord Lister in later years, congratulating him upon his Caesarean sections, and inquiring what methods he had pursued. His reply had been, "I pursued the methods which I had learned in your wards." Lister's sympathy was wide and human, and his pity tender and true. The death of his coachman, who was killed in front of his ward, had affected him most profoundly.

Professor ARCHIBALD YOUNG, Lord Lister's successor in the Regius Chair of Surgery, proposed a vote of thanks to the previous speakers, who had helped him to see Lister plainer, and paid homage to the master and Sir Hector Cameron, his beloved disciple.

The processional and other arrangements of the day were made and supervised by Sir John S. Samuel, K.B.E., and Mr. G. H. Edington, surgeon to the Western Infirmary and lecturer in surgery at the University, who acted as joint honorary secretaries of the organizing committee, and to whom much credit was properly ascribed by all, for the precision and smoothness of the proceedings.

THE LISTER CENTENARY CELEBRATIONS IN LONDON.

RECEPTION OF DELEGATES BY THE KING.

THE first event in the official ceremonies of the celebration in London of the centenary of Lord Lister's birth was the reception by the King in the Throne Room of Buckingham Palace of the delegates who have assembled from all parts of the civilized world. The Minister in attendance was the Home Secretary.

ADDRESS BY THE ROYAL SOCIETY.

After the King had received and shaken hands with each delegate an address was presented by the President of the Royal Society (Sir Ernest Rutherford). In it Lord Lister was described as one of the greatest benefactors of the human race. His brilliant powers as an investigator and his single-minded devotion to science had enabled him, in applying to the problems of surgery the discoveries of his great contemporary Louis Pasteur, to lay bare the hidden causes of septic inflammation, and to discover means for its prevention, thereby inaugurating a new epoch in the science and practice of surgery. "It may well be doubted," the address continued, "whether the scientific activity of any one man had achieved so much for the saving of human life and for the prevention and relief of the physical sufferings which afflict mankind."

THE KING'S REPLY.

I thank you for the address which you have presented. It is with pleasure that I receive the delegates who are present here to-day, and so take part in the centenary commemoration of Lord Lister's birth. Any country might be proud to claim Lord Lister as its citizen; and I and my people heartily welcome the representatives of medical and surgical science, both from the Overseas Dominions and from all parts of the civilized world, who have come to join us in honouring his memory.

You have truly said that Lister ranks among the greatest benefactors to mankind. Of all the many changes in the last hundred years, none is more striking than the revolution in thought concerning surgery. It is hard now to realize the dread and apprehension with which formerly even a minor surgical operation was regarded. This change in our ideas is due partly to the discovery of anaesthetics and perhaps even more to Lister's work. Lister removed the horror of sepsis from surgical operations, and for this he is rightly described as the father of modern surgery. The principles discovered and laid down by him are to-day being worked out by his successors and are still fruitful of new applications.

Naturally a layman looks first at the ultimate success and beneficent effects of Lister's work. These, however, were not the outcome of happy accident or sudden inspiration, but of long and patient study, of continuous experiment, and finally of a wide knowledge and penetrating insight, enabling him to discern the importance and practical bearing of observations which, to some minds, might have remained a piece of academic research.

It is my earnest desire and hope that the Lister centenary celebrations may be in every way successful, and that this gathering of men of science from every quarter of the globe may conduce to foster and to strengthen the co-operation of all nations in the accumulation of scientific knowledge for the common benefit of the human race.

RECEPTION OF DELEGATES AT BRITISH MEDICAL ASSOCIATION HOUSE.

THE PRIME MINISTER'S TRIBUTE.

THE Great Hall of the British Medical Association House in Tavistock Square was a fitting scene for the reception by the Prime Minister on Tuesday morning of the delegates attending the Lister celebration. The official delegates themselves formed a considerable audience, but many other members of the profession and the public were present, and the fact that the date coincided with that of the Council meeting of the British Medical Association made it possible for most of the members of Council to be present. A very large number of those in attendance wore academic dress, and the costume of some of the delegates from foreign universities struck an unusual, almost a gorgeous, note.

The chair was taken by Sir ERNEST RUTHERFORD, O.M., President of the Royal Society, and chairman of the General Committee of the celebration. He was supported by Mr. Robert Hogarth, C.B.E., President of the British Medical Association, Sir John Rose Bradford, President of the Royal College of Physicians, and chairman of the executive committee in charge of the arrangements, Sir Berkeley Moynihan, President of the Royal College of Surgeons, Sir James Berry, President of the Royal Society of Medicine, Sir Charles Sherrington, Sir Humphry Rolleston, and others.

Mr. Baldwin, who was very cordially received, delivered a brief but eloquent appreciation of Lister, and afterwards shook hands with not far short of one hundred official delegates, and listened to two discourses, by a distinguished Frenchman and a distinguished German, dealing with the effect of Lister's work on surgical and pathological science and practice in their respective countries.

CHAIRMAN'S INTRODUCTION.

Sir ERNEST RUTHERFORD welcomed Mr. Baldwin, whose presence at that gathering, he said, showed that the State was not unmindful of the debt it owed to one of its greatest sons. This was a memorable occasion on which honour was being done to the memory of one of the greatest figures in the history of the application of science to surgery. It fell to few men to leave behind them, as

Lord Lister had done, such a splendid and permanent memorial of personal achievement. In the course of the celebrations some of the most distinguished men in the field of science in which Lister laboured would give appreciations of Lister's services to science and humanity. He himself had no claim to speak with authority on these matters, but it was not necessary to be a specialist to recognize what a debt the whole world owed to the discoveries of Lister and to his single-minded devotion to the cause of suffering humanity. As President of the Royal Society—an office which Lister himself filled with such distinction—he valued very highly the privilege of presiding on that occasion, and of extending a cordial welcome to the delegates who had assembled from many quarters to do honour to Lister. In addition to the addresses which would be presented formally by the delegates, some messages had come to hand from others who, by reason of distance, were not able to attend.

Those telegraphing messages of congratulation and homage included the following:

From the Imperial Academy of Tokyo,
From the State Institute of Experimental Medicine, Leningrad, and
From Semmelweis's Fatherland (sent by Dr. Emile de Grosz, President of the Hungarian Post-Graduate Committee).

MR. BALDWIN ON "A MAN OF REAL GREATNESS."

The PRIME MINISTER said:

Sir Ernest Rutherford, you have bestowed upon me a very high honour to-day in asking me to be present to receive the delegates who have come from all parts of the world to do honour to one of the greatest Englishmen of all time. In welcoming the delegates, I would say only a few words to them before I have the pleasure of receiving them personally. To-day the boundaries of all the nations are broken down in this hall. It is only fifty years ago that Joseph Lister came to London to convert his own people. It was two years after that, before he had attained that recognition here which subsequently was lavished upon him, that at an international congress in Amsterdam he was greeted by his colleagues in the profession from all over Europe in words uttered by the chairman on that occasion which we may well recall to-day: "Professor Lister, it is not only our admiration that we offer you, it is our gratitude and that of the nation to which we belong." These are words which found their echo years afterwards, not from the lips of an Englishman, but from the lips of a great American, showing how world-wide was his constituency, when at a dinner of the Royal Society that great ambassador, Mr. Bayard, in proposing Lister's health, said: "My lord, it is not a profession, it is not a nation, it is humanity itself which with uncovered head salutes you."

I cannot think that such a gathering as this would have been possible had it not been that in Lister there were all the complementary parts that go to make a man of real greatness. There was in him that to which you can testify with more authority and with more knowledge than I. I come here to greet the memory of the great master workman in his own craft, the man who pursued his science empirically and also by applying the newly discovered knowledge of his age to practical problems, and by devoting years of his life in that pursuit—the master workman who by that work of his brought more relief, more comfort, to the human race than almost any man who has ever lived. But there is also the other side—there is the man himself. To that I think it is allowable for a statesman to pay his tribute as much as for anyone of Lister's own profession, because in him there were those very things we most admire when we see humanity raised to its highest point. There was the wonderful simplicity and integrity of his nature—a man truth-loving, truth-seeking, and truth-living, a gentle man, filled with charity and with devotion, a man with never a mean thought. These things we find allied and brought to supremacy in his own work.

I would say only this further, that no more fitting words could have been uttered of him than the words which were sung at the great memorial service in Westminster Abbey fifteen years ago, to the music of one who himself brought the nations together—the great Handel, who might be called both a German and an Englishman. The words were these:

"When the ear heard him then it blest him, and when the eye saw him it gave witness of him. He delivered the poor that cried, the fatherless, and him that had none to help him. Kindness, meekness, and comfort were on his tongue. If there was any virtue, and if there was any praise, he thought on these things. His body is buried in peace, but his name liveth for evermore." (Loud applause.)

RECEPTION OF DELEGATES.

The following delegates, representing foreign countries, overseas dominions, and British seats of learning, medical societies, and hospitals, were then presented to the Prime Minister, to whom many of them handed addresses from their respective bodies commemorative of Lister's work:

Dr. Otto Stapf (Austria), Professor A. Krogius (Finland), Dr. P. Bazy, Professor Hartmann, and Dr. P. Vallery-Radot (France), Professor von Gruber, Professor A. Kossel, and Professor Max Rubner (Germany), Professor C. F. A. Koch (Holland), Professor Johan Nicolaysen (Norway), Professor C. Kostanecki (Poland), Sir Arthur Schuster (Spain), Professor S. G. Hedin (Sweden), Professor de Quervain (Switzerland), Professor Melvin S. Henderson, Professor de Witt Lewis, and Professor W. G. Maccallum (United States).

Professor Kerr Grant and Mr. Hamilton Russell (Australia), Professor Irving Cameron and Professor S. B. Whitnall (Canada), Major-General J. B. Smith (India), Professor D. Colquhoun (New Zealand), Dr. Watkins Pitchford (South Africa).

Sir John Rose Bradford (Royal College of Physicians, London), Sir Charles Sherrington (Royal Society), Sir Berkeley Moynihan (Royal College of Surgeons of England), Professor G. M. Robertson (Royal College of Physicians, Edinburgh), Mr. Logan Turner (Royal College of Surgeons, Edinburgh), Professor Andrew Fullerton (Royal College of Surgeons in Ireland), Dr. G. H. Edington (Royal Faculty of Physicians and Surgeons of Glasgow), Sir George Newman (Royal Society of Edinburgh and Ministry of Health), Professor Graham Kerr (Royal Philosophical Society of Glasgow).

The following representatives of Universities: Sir Archibald Garrod (Oxford), Sir Humphry Rolleston (Cambridge), Professor Percy Herring (St. Andrews), Professor Archibald Young (Glasgow), Professor John Marnoch (Aberdeen), Sir Harold Stiles (Edinburgh), Sir William Taylor (Dublin), Sir Holburt Waring (London), Mr. Grey Turner (Durham), Professor Craven Moore (Manchester), Professor A. W. Sheen (Wales), Professor Leonard Gamgee (Birmingham), Professor Thelwall Thomas (Liverpool), Professor Kay Jamieson (Leeds), Professor E. Mellanby (Sheffield), Professor E. Fawcett (Bristol).

Surgeon Vice-Admiral Sir J. Chambers (Navy Medical Service), Lieut.-General Sir Matthew Fell (Army Medical Services), Air Vice-Marshal D. Munro (Royal Air Force Medical Services).

Sir Walter Morley Fletcher (Medical Research Council), Lord Somerleyton (King Edward's Hospital Fund for London), Dr. E. M. Callender (Medical Society of London), Mr. R. G. Hogarth (British Medical Association), Sir James Berry (Royal Society of Medicine), Sir Cuthbert Wallace (Association of Surgeons of Great Britain), Professor E. H. Starling (Lister Institute), Sir Frederick Andrewes (Pathological Society), Sir David Wallace (Medico-Chirurgical Society of Edinburgh), Dr. J. A. Murray (Royal Microscopical Society), Sir Frederick Fry (Merchant Taylors Company), Mr. Alfred Hepburn (Society of Apothecaries), Professor J. P. Hill (University College, London), Dr. Ernest Barker (King's College, London).

Also the following representatives of hospitals: Dr. H. Morley Fletcher (St. Bartholomew's), Mr. Charles Gibbs (Charing Cross), Mr. Walter Fedden (St. George's), Mr. F. J. Steward (Guy's), Mr. Arthur Cheatle (King's College), Professor W. Bulloch (London), Dr. C. M. Wilson (St. Mary's), Dr. E. Pearce Gould (Middlesex), Mr. Cyril Nitch (St. Thomas's), Dr. A. M. H. Gray (University College), Mr. William Turner (Westminster), Lady Barrett (London School of Medicine for Women), Dr. George Mackay (Edinburgh Royal Infirmary), Dr. W. G. Black (Glasgow Royal Infirmary), and Colonel Donald Mackintosh (Western Infirmary, Glasgow).

A FRENCH APPRECIATION.

Two discourses by eminent foreign delegates, one from France and the other from Germany, were then delivered.

Professor HENRI HARTMANN of Paris, who addressed the gathering in French, said that when the Académie de

Médecine appointed him to represent it at the centenary of Lord Lister he gladly accepted the honour because of the opportunity it gave him of expressing the homage of the French medical profession to one who had wrought a revolution in surgery. In the middle of the last century one of their greatest surgeons, Nélaton, wrote that if a man could discover a means of suppressing purulent infection he would deserve a statue of gold. Such a statue Lister had merited. Before his work all interventions with the knife were threatened by the most dangerous complications. The fear of erysipelas caused the surgeon even to refrain from incising an abscess; he preferred to await its spontaneous opening. But from the day when the ideas of Lister came into practice the aspect changed completely—interventions with the knife lost their immense risk, and surgical procedure was revolutionized.

Previous to Lister several French workers, Déclat, Lemaire, Maisonneuve, Demarquay, had been using carbolic acid in the dressing of wounds. The results obtained had been mediocre. But Joseph Lister, employing the same agent, the disinfecting action of which on sewage had already been proved, obtained results beyond anything which had been suspected, and the method as he employed it was not an empirical one, but rested upon a scientific basis.

From 1860 to 1866 Pasteur, by a series of carefully conducted experiments, had established his great work on fermentation—had shown that the various fermentations, instead of having a spontaneous generation, depended upon organisms conveyed in the air. To Lister must be given the immense credit of seeing the value of these experiments in their application to the treatment of wounds. Adopting the ideas of Pasteur, and repeating his experiments in a somewhat modified form, he came to the conclusion that the complications seen in wounds were due to infection by germs introduced in this way.

In 1867 he began the series of papers which immortalized his name. He had not simply come upon an effective disinfecting agent; he had constructed a method. He showed that to avoid wound infection the wound must be protected from the entrance of germs, that care must be taken to disinfect everything that touched the wound—the hands, the instruments, the sponges, the dressings—also that by the operation of a carbolic spray the germs in the surrounding air must as far as possible be destroyed. At the same time, he substituted for the ligatures formerly in use a new absorbent ligature, and he followed a carefully thought out practice with regard to reunion of the wound and to drainage. The results were now a matter of history. In the Glasgow Royal Infirmary the mortality following compound fractures fell on the adoption of the Lister method from 40 to 3 per cent. Erysipelas, purulent infection, septicaemia, hospital gangrene, and other complications disappeared from the wards.

An Ardent French Disciple.

A year after the publication of Lister's first paper (continued Professor Hartmann) a young hospital resident physician of Paris, Just Lucas-Championnière, visited Glasgow. He saw there, to his great astonishment, wounds healing without suppuration, reunion obtained by first intention, with a rapidity which he had not thought possible. He saw no erysipelas, no septicaemia, no purulent infection, no hospital gangrene, no suppuration even. *Returning full of enthusiasm, he published, in January,* 1869, the first French article on Lister's method, then unknown in most countries. Subsequently he preached Listerism and succeeded in inducing a number of surgeons to follow the practice of Lister in their hospitals. When Lucas-Championnière himself became the head of a hospital service he applied in the most exact manner the Lister method. The difference between the results of the old method and of the new was apparent to all eyes. In 1876 this disciple published his *Chirurgie antiseptique*, the first didactic work to appear on the method of Lister. Thus France was one of the countries where the method of Lister was most rapidly accepted.

Its adoption made a veritable revolution in surgery. This could be gathered from a study of the Bulletins of the Société de Chirurgie, which furnished a record of surgical progress in France. From the year 1875 the discussions differed altogether from those which had appeared previously. The procedures of surgical intervention with the knife in various directions entered upon a new phase. Surgery was wholly transformed by the safety of the Lister method. The new fields which opened out in consequence were the subject of numerous communications to the society, and the successes obtained by surgeon after surgeon appeared the more astonishing when contrasted with what had taken place before.

After recalling how Lister was acclaimed in Paris when he visited that city, and what eagerness there was to see the man who had so profoundly modified the practice of surgery, the speaker mentioned that in 1882, when he himself was a resident physician in a hospital, he made a pilgrimage to this country, as Lucas-Championnière had done fifteen years before, and saw Lister, who was then at King's College Hospital. He would ever retain the feeling of admiration which he, a young student, felt at that time for this great master.

Surgery, since Lister's discovery, had continued to evolve. Asepsis had succeeded antisepsis. For the destruction of germs by carbolic acid there had been substituted their destruction by heat, which produced an absolute sterilization, and was free from the inconveniences which attended, in certain circumstances, the contact of the antiseptic with the living tissue, and less importance was attached now than formerly to germs contained in the air. Nevertheless the principles propounded by Lister remained, a permanent acquisition.

In conclusion Professor Hartmann said:

"Aussi le nom de Lister restera-t-il dans l'histoire comme celui de l'homme de génie qui, en appliquant au traitement des plaies un méthode reposant sur un base scientifique, a permis à la chirurgie de faire, en une courte période d'années, des progrès tels qu'on n'en avait jamais vu de pareils dans les siècles antérieurs." (Loud applause.)

Listerism in Germany.

The second discourse was delivered by Professor Max Ritter von Gruber of Munich.

Professor von Gruber said that the work of Lister was a memorial which proclaimed more impressively than any other achievement the blessings of science, and disclosed to the eyes of all nations what immeasurable advantage scientific discovery and method in a humane direction could bestow upon the world. The greatest triumphs in the prevention of disease and its eradication were the introduction of vaccination by Jenner, the work done on puerperal fever by Semmelweis, and the antiseptic treatment of wounds by Lister. Lister's achievement, over and above its immediate practical utility, represented also a great gain from the point of view of intellectual development. While the first two achievements just mentioned were the result of empirical discovery, Lister's method was the result of theoretical insight following from the deductions of experimental natural philosophy. Lister's glory was also the glory of Pasteur, for Lister built his practice upon the scientific foundations which Pasteur had laid. Pasteur proved that materials liable to putrefaction never putrefied by themselves, but only when microbes multiplied in them, and that these microbes were originally introduced from without. He proved also that when materials liable to putrefaction came into contact with the air and putrefied, the cause was not the oxygen or other constituents of the air, but the germs which the air contained. These facts, established by Pasteur, convinced Lister that putrefaction in wounds was due to the entrance of germs, and that therefore it must be possible to take measures to prevent such complications. The report from Carlisle regarding the treatment of sewage by carbolic acid led Lister to employ this agent in order to cleanse the wounds of germs which might be already present and to disinfect the surrounding parts, the hands of the operator, the instruments, and the dressings. At the same time he tried to protect the wound from invasion of micro-organisms from without

by the use of special dressings. After many years of tireless work Lister perfected his method, which he thought out to the minutest details. The results of his meditations and endeavours surpassed his boldest hopes.

No doubt very few of those present had seen, as the speaker had seen, a surgical ward where the old-fashioned pre-Listerian methods were employed. Those who had not had that experience could scarcely imagine what awful things there met the eye. Only the great war brought back a resemblance to those long-forgotten horrors. In those old days nobody ever expected any large wound to heal without lengthy suppuration and copious scar-formation. So long as nothing worse than this happened the surgeon was satisfied and happy. He (Professor von Gruber) could see those patients still before his eyes, the septicaemic, the pyaemic, the tetanic, the patients with erysipelas, their heads and faces irrecognizably swollen. He could see the pads of lint dripping with pus taken out of the large caverns of the abscesses, the glowing iron by the help of which the surgeon tried to master the gangrene of the wound while sacrificing sound tissues irretrievably. And the people thus suffering were not by any means all of them old and debilitated; many were young soldiers, and not all of them had extensive lacerations of open bone fractures or other wounds which in all circumstances, and even to-day, were dangerous from the point of view of infection; most of them had been carefully operated upon. Even this was not the worst that might happen. Hospital gangrene might claim large numbers of cases. He recalled how it raged in the Munich surgical hospital in the early seventies. In 1874 no less than 80 per cent. of all those wounded or operated upon fell victims to gangrene. The smallest puncture, a corn-cut which had gone a little too deep, a cupping spot, a leech-bite, even a blister produced by a vesicant, could become gravely dangerous for limb and even for life. Out of sixteen amputation cases eleven died of pyaemia. And yet in that very same hospital Professor von Nussbaum could show his students, one day in 1875, but a few weeks after he had begun to "lister," as they said in Germany, that at the moment there was not one new case of pyaemia or of gangrene there, but that all the wounds were healing faultlessly and quickly.

The Slow Progress of Lister's Method.

Perhaps the present audience (Professor von Gruber continued) might be surprised to hear that in 1874, seven years after Lister's first publication, his method was not employed everywhere in Germany. But even in Great Britain things were not very different. That many years had to elapse before Lister's discovery came to be universally put into practice was not to be attributed merely to human blindness in the face of all that was new, or to vanity and jealousy of colleagues; there were more substantial reasons. The corroboration by microscopical or cultural proof of Lister's teaching as to certain micro-organisms being the cause of wound infections was not forthcoming for a long time. A still greater hindrance was the fact that Lister's method as first published was not the fully developed method; it was improved and developed by Lister himself when he brought forward his so-called permanent dressing in 1871. The subtle manipulations which his method required had to be learned most exactly and carried out most punctiliously, for defective execution brought many failures. The procedure was also very expensive. The use of concentrated solutions of carbolic acid produced severe poisoning, and even the inevitable breathing in the carbolic vapour was dangerous. For all these reasons the new treatment of wounds only slowly won its way.

Some prominent German surgeons were among the first to appreciate the greatness of Lister's invention. In 1871 Surgeon Major A. W. Schultze visited Lister in Edinburgh to learn his method at first hand, and in the following year, in the *Deutsche militärärztliche Zeitschrift*, he reported what he had seen there. It was the first time that exact details about the new treatment were made known in Germany. Professor v. Bardeleben, in Berlin, and Professor Volkmann, in Halle, were the first to begin at once to treat according to Lister's prescriptions. The latter in 1871 had been so distressed by the cases he had seen in his own hospital that in despair he was considering closing his hospital altogether. Professor von Nussbaum was the third clinician to take up the method after his assistant Lindpaintner had been Lister's scholar in Edinburgh.

The town from which the speaker came, Munich, was the first to proclaim the immortal glory of Lister. He was received there in 1875, and reverence was paid to him then as one of the greatest benefactors of mankind.

The Triumphal March of Listerian Surgery.

It would be erroneous to suppose that previous to Lister no means of preventing these wound infections was known. When he himself was a student in Billroth's clinics in Vienna the so-called "open-wound treatment" by Weber and Billroth was practised for years, and worked excellently in the treatment of such operations as could be ventured in those days. It was in itself a kind of antiseptic method. But what did the boldest surgeon venture at that time? To-day the great probability—almost the certainty—of avoiding wound infection by careful operation had opened fields to surgery which were undreamed of fifty years ago. Under Lister's banner surgery began an incomparable triumphal march, and greater conquests were made in two decades than had been made in two millenniums before. True, many of the original precautions practised by Lister in the treatment of fresh wounds had proved to be superfluous. Infection from the dust in the air was not so greatly feared, and the aseptic method, which avoided as far as possible the contact of the wound with chemicals, had been substituted for the antiseptic. But the principles of Lister remained unshaken. His discovery was and would be the ground-work of all wound treatment. It was also of great biological importance. Formerly the living organism had seemed to be a very frail structure, its organs extremely susceptible to mechanical disturbance. Only after Lister's work did it become evident to what an astonishing extent the organism reacted in the direction of the preservation of life, and how capable it was of regeneration.

In conclusion, Professor von Gruber said that thirty years ago he had the fortune to enjoy close intercourse with Lord Lister for some days. The thought that he had been of use to mankind was the greatest happiness of Lister's life. The beauty and nobleness of his appearance were in complete accord with the harmony and magnanimity of his character. The tender glance of his blue eyes was not to be forgotten by any who met it. Lister was one of the most glorious blossoms the tree of mankind had ever borne. He believed, and worked in the belief, that there was no more sublime aim for human striving than to discover ways and means to diminish the sum of sufferings and augment the joys of mankind. Very often when they felt driven to despair in the face of human vileness the memory of Lister came before the mind as a shield from pessimism. The thought of this great and pure soul would always make them hope anew. (Loud applause.)

VOTES OF THANKS.

Sir ERNEST RUTHERFORD, in thanking the Prime Minister, said that he did not know whether Mr. Baldwin ever met Lord Lister, but he was sure they would have delighted in one another's company. He also thanked the two speakers. All those present were sensible of the great debt which the whole world, and Lister himself, owed to the great Frenchman Pasteur. Lister knew that his own work rested on the pioneer experiments of Pasteur on fermentation. They also appreciated the debt that admirers of Lister owed to Germany and to France for the way in which those countries took up at an early date Lister's discoveries. Further, he had to thank Mr. Hogarth, as President of the British Medical Association, for lending the beautiful and appropriate hall of the Association for the ceremony.

MEMORIAL MEETING AT KING'S COLLEGE HOSPITAL.

TRIBUTES BY FORMER PUPILS.

THE Listerian Society at King's College Hospital, London, of which Lister was President in 1877, just fifty years ago, celebrated the centenary at a large meeting on Monday afternoon, when addresses were given by Sir W. Watson Cheyne, Bt., and eight or nine others who had been closely associated with Lister, especially during the years at King's College. The chair was taken by Mr. ARTHUR CHEATLE, president of the society, who said that King's College Hospital kept that day with gratitude and pride—gratitude that such a man as Lister was ever born into the world, and pride because he was a fellow-countryman and closely attached to the hospital as surgeon and consulting surgeon for thirty-five years. To help them celebrate their centenary they welcomed Sir Watson Cheyne, Lister's chief apostle and a "King's" man.

Sir WATSON CHEYNE spoke of Lister as a man rather than as a scientist. Fifty years ago Lister received an urgent invitation from the authorities of King's College Hospital, then in the vicinity of Lincoln's Inn Fields, to come to London to fill the place in that hospital vacant by the death of Sir William Fergusson in the preceding year. The request came as a thunderbolt to Lister. He had settled down in Edinburgh, and was supremely happy there, where he had friends who loved and admired him, and where he had very large classes of enthusiastic students whom it was his joy to teach. At first he declined the proposal, but renewed requests were made, and he ultimately agreed to come to London, being chiefly influenced by the argument that his views and methods of treatment would spread more quickly from the metropolis than from Edinburgh, and by the fact that, although eleven years had elapsed since his first publications, really very few surgeons in London had taken up his methods. Before Lister made his final decision he came to the Infirmary early one morning and woke up his house-surgeon (the present speaker) to ask him whether he would go to London with him. Three other students were also asked to go as clerk and dressers, and the four of them were naturally very much excited and pleased at the prospect of following the master. They felt very much as the old crusaders must have felt. In London Lister missed sorely the numbers of students who followed him and filled the lecture room at Edinburgh. When the students at King's, at that time quite a small school, attended his lectures in small numbers and looked bored, he was very pessimistic, and for some years the speaker tried to attend his lectures whenever he could manage to do so because he knew how much the presence of senior men pleased and comforted him. For some time it appeared as if they had struck a poor type of student at King's, but later it was discovered that the examining bodies did not favour "Listerism," and that the students were afraid to introduce the subject, desiring, in fact, not to learn Lister's views until they had passed their examinations. One of the greatest characteristics of Lister was his extreme conscientiousness. His care in his papers and addresses to ensure as great accuracy as possible had the curious result that when he had to deliver any important address he was almost certain to arrive late at the meeting, the explanation being that, on going over the points of his discourse before leaving home, something had occurred to him as not sufficiently proven to justify a positive statement, and he would, even at the last moment, set to work to look into the matter. When about to deliver before the Royal Society the Croonian Oration on the coagulation of blood, it was said that a point struck him after he had left his house, and he turned into a slaughterhouse and had an animal bled in order that he might make the necessary observation. His conscientiousness was shown also with his patients. If they complained of pain or discomfort he would set to work to rearrange dressings, splints, and pillows, irrespective of other engagements, thereby making himself late for appointments. For this reason—the likelihood of appointments with busy practitioners not being punctually kept by him—he never had a large private practice. When asked to give an opinion in a case on which he was not himself to operate he was troubled a great deal. In many cases the opinion that he felt to be the correct one might depend entirely on whether the wound would remain aseptic or not. If he advised an operation in which asepsis was essential, and the operation was not done by him, or by someone who believed in and practised asepsis, his opinion, if acted on, might practically condemn the patient to death. In this transition period, therefore, he quite rightly looked on an opinion given by a surgeon as applying only to his own handling of the case afterwards, and he was very much against those who gave advice after they had ceased to operate. The speaker also mentioned Lister's sympathy with sufferers, and his readiness to help, sometimes much abused. In spite of numerous ovations, Lister remained throughout life a humble and unaffected man. He appreciated all his honours, but they made no difference in his relations with other people, nor did he show that he was conscious of meriting any special respect.

Sir GEORGE LENTHAL CHEATLE said that Lister was in every way the greatest man he had met. Lister's devotion to his work and his great courtesy had caused all who had come in contact with him to revere him. To Lister the hospital was a temple, and he would endure no infringement of its sanctity. On one occasion he performed a brilliant operation in thirty-two seconds, and when the onlookers cheered him he turned round and said, "Gentlemen, remember where you are." Lister would not tolerate inefficiency, and had never made an inaccurate statement. On one occasion he told the speaker that he did not wish to retract anything he had said or written. The legacy which Lister had left to mankind would be everlasting. Those of his fellow-men who had felt his personal influence knew that the place filled at his birth and left vacant at his death could never be filled by anyone else.

Colonel BOND told many personal reminiscences of Lister, and gave instances of how he had benefited by having learned at his feet. He recalled how at the Medical Congress of 1881 well known surgeons from all parts of the world had come to listen to Lister, and described how, by the use of Lister's methods, Sir Thomas Crawford and himself had saved numbers of cases in the Egyptian campaign and the Boer war which otherwise would have surely proved fatal. No proof was needed of the boon and blessing which Lister had been to surgery.

Sir STCLAIR THOMSON said the "old antiques" on the platform could go back to the time when most of the hospitals in the country reeked with the stench of putrefaction, and he himself could remember when he had been temporary house-surgeon at King's Lynn, at which time the only operations carried out there had been amputations, and underneath each stump used to be placed a tin tray to collect the dripping pus. The wounds were dressed with oakum, and from the gaping wound there used to hang the hemp ligatures, used before the days of catgut. Those who came in contact with Lister for ever remembered his magical influence and extreme modesty. Like all great men, Lister was very particular about details. He used to show students how, in bandaging a chest, the turns of the bandage above and below the breast had to be fixed with a safety-pin; otherwise they drifted apart, and, in order to impress that upon his hearers, he used to tell the incident of how he had had on one occasion to open an abscess in the axilla for Queen Victoria. All had gone well, but on reaching the railway station to go home he suddenly remembered that he had forgotten the safety-pin. He immediately returned to Balmoral Castle, and explained the oversight to Queen Victoria and the necessity for making her undress so that he might put in the safety-pin. Some surgeons would perhaps have chanced that safety pin.

Mr. R. HAMILTON RUSSELL, F.R.C.S. (Melbourne), remarked that Lister appeared to one in various guises—first, as an operating surgeon, secondly, as a most delightfully lucid lecturer, and thirdly, and greatest of all, as supreme and without rival as a dresser of wounds at the bedside. He had been putting together a short time ago a few reminiscences for the Edinburgh Memorial Volume, and it had occurred to him to estimate what

proportion of Lister's teachings to his students had consisted of the art of dressing wounds; he had come to the conclusion that, on a rough calculation, 75 per cent. of Lister's teaching had been devoted to that art, and 25 per cent. to what might be called ordinary textbook surgery. It was very rarely nowadays that the Lister anæsthesia was referred to; it had been a side-interest of Lister's, which had been completely obliterated by the greatness of his supreme achievement. Nevertheless, Lister had been a great scientific experimenter in anæsthetization; he had written in Holmes's *System of Surgery*, 1883, the best articles on the practical administration of chloroform that had ever been published. Sir Watson Cheyne had put the question, In what did the genius of a man like Lister consist? It was exceedingly difficult to answer such a question, but whenever one met a man with superlative ability of intellect or nobility of spirit, or both combined, as in the case of Lister, one was certain to experience extraordinary interest and great moments. In reply to a compliment, Lister had once said, "Yes, that is a thing which will rejoice the heart of any man who loves his fellow-men," and he had never known any man other than Lister who could have said that and have conveyed conviction of the genuineness of his feelings on the subject. Lister had really loved his fellow-men; he had had, in fact, the philanthropic temperament. He was a great lover of children. At a clinical lecture Lister was once discussing the treatment of the patient, who happened to be a little child, and he said, "We must always remember that when the patient is a child it adds to our responsibilities. An adult is able to decline any treatment suggested, and the patient, therefore, in that case can share the responsibility with the surgeon; but in the case of a little child it is absolutely at our mercy, and that should make us all the more cautious about anything we undertake to do to their sacred little bodies."

Dr. H. P. WARD said he well remembered his first impression of Lister's outstanding personality, and his fine physique and noble physiognomy. All knew what strength he could exert if necessary, and his powers of endurance. When one studied his features, who could doubt that there was intellect above the average? His strength of mind and purpose was indicated by his noble spreading forehead, his deep clear eyes, and thoughtful but benign expression of countenance. Work had been Lister's life occupation —work done with the noblest of all objects, namely, the relief of human suffering. To his example and teaching of truth and sincerity and the sacredness of human life, his kindness and consideration to all his patients, his hard work and attention to detail, those who were his pupils owed whatever of those excellent qualities they had exhibited during their professional careers. He for one looked back on his years of guidance under Lister as his most precious years of experience, and he voiced his sincere gratitude to his teaching and influence.

Mr. L. V. CARGILL called to mind Lister's noble presence, his quiet dignity, and his earnest teaching and constant example, which created amongst those who worked with him an atmosphere which brought out one's best efforts to attain the sort of standard and high ideals and unstinted service which Lister would wish. Remarks had been made about examination and teaching. He could recall how Lister used to regret the time which men seemed to find it necessary to give to that form of teaching which was specially adapted for the examination room. The teaching that Lister gave was of a kind which was of the greatest use to his pupils, not perhaps for the mere purpose of examination, but for the purposes of life after the examination was concluded. Lister reminded him of Shakespeare's lines:

> "What a piece of work is man! How noble in reason! how infinite in faculties! in form and moving, how express and admirable! in action, how like an angel! in apprehension, how like a god!"

Dr. H. DISTIN described how being attached to Lister used to have its drawbacks. His fellow-students used to say that if one dressed for Lister one never learned anything, because he did not teach one any surgery; that whereas the other surgeons in the hospital did brilliant operations, Lister's cases were all chronic patients whom he kept in the ward for six or nine months. Time had proved that such scepticism of Lister's principles had been wrong, and no one would say now that Lister had not taught surgery. It had certainly been trying for anyone attached to Lister to have to go round the wards with him accompanied by only the dressers while other surgeons were accompanied by crowds of students. But besides his dressers Lister used to be accompanied by numbers of German and French doctors, who treated Lister as a sort of god. The dressers used to have to listen to long dissertations in French and German by Lister, and as few of the students understood a word of it that was probably one reason for the prevailing unpopularity of serving with Lister. Lister had taken a long time to become popular owing, among other reasons, to the ultra-conservatism of the London surgeons, who could never learn anything from the provinces or other places. An incident which showed Lister's strength of character was as follows. The anti-vivisectionists of the day had induced Queen Victoria to instruct her secretary to write to Lister, asking him to denounce vivisection. If anyone desired to read Lister's courageous reply they could do so in Sir Rickman Godlee's *Life of Lister*, where they would see how he had said that he would be lacking in his duty to humanity if he protested against animals being experimented on. When it came to a question of conviction Lister was no courtier, and he had simply told Queen Victoria that he would not

do what she asked him to do. Just as the history of England was written in two parts—the nebulous part prior to the Norman conquest, and the more precise part since, so the history of British surgery would be divided into two parts—the pre-Listerian era and the period subsequent to that time.

Dr. H. PERRY paid a tribute to Lister's outstanding charm of personality. He was a man of very deep religious convictions, but absolutely free from any form of bigotry. He had said on one occasion that if a man did his duty on this earth he had nothing to fear elsewhere. He was a brave man, but infinitely cautious, studying a major operation as though he had never done such an operation before. Personally he sometimes wondered whether Lister's personality was not even greater than his vast achievements.

Dr. A. BOUSFIELD said he had come in contact with Lister at the very end of his active hospital career, but his interest in every detail of his cases had not abated in the very least on the last day he went round the wards.

The CHAIRMAN, before closing the meeting, announced that he held in his hand a unique record of Lister—namely, an *x*-ray picture of Lister's hand. It was the most intimate relic existing of Lister.

UNIVERSITY COLLEGE HOSPITAL.

Two laurel wreaths were placed over the Lister memorial tablet at the main entrance of University College Hospital on the morning of April 5th, as tributes from the general committee and the Medical Society. Sir ERNEST HATCH, chairman of the hospital, who presided over the ceremony, gave a short account of Lister's connexion with the hospital, which he entered in 1844. Five years later he was appointed house-physician, and the year 1851, when he became house-surgeon, brought with it the fulfilment of the desire Lister had expressed in boyhood—namely, that he wanted to be a surgeon. He published two important papers in early life; one was written in the hospital in 1853, and received high commendation by distinguished authorities. The first operation in London under an anaesthetic was performed by Robert Liston, another member of University College Hospital, and Lister was invited to be present. Soon after this he left the hospital to pursue his life's ambition in Edinburgh, and, later, in Glasgow. Sir Ernest Hatch added that while Lister was at University College Hospital he had the good fortune to be instructed by Wharton Jones, professor of surgery, and William Sharpey, professor of physiology, the former of whom was then making his celebrated investigations into the circulation of the blood and the phenomenon of inflammation. Sir Ernest Hatch expressed his belief that these two great professors were the presiding geniuses over Lister's early career and the inspirers of his subsequent triumph.

ROYAL SOCIETY OF MEDICINE.

A SOCIAL evening was held at the Royal Society of Medicine in connexion with the Lister centenary, when the numerous guests were received by the President and Lady Berry. Relatives of Lister were present, and delegates from the United States and Continental countries. Sir STCLAIR THOMSON delivered an eloquent address based on his recollections of his experience as one of Lister's house-surgeons. This address, which is published at page 659, was illustrated by a series of photographs of Lister at different ages, and of some of the institutions where he worked, a pleasant feature being the careful arrangement by which demonstration of the lantern slides did not interrupt the speech, but served to illustrate its cardinal points. Various exhibits lent by the Wellcome Historical Medical Museum were on view in the library.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A CONVERSAZIONE given by the Royal College of Surgeons of England at Lincoln's Inn Fields on the afternoon of April 5th was largely attended. Among the guests were a number of delegates who had been presented to the Prime Minister in the morning. Besides the library and the portraits and busts which much interested the visitors, the collection of instruments once belonging to Lister, and of his letters and notebooks and other documents, attracted a crowd of surgeons and their friends. The instruments are referred to in some detail in another part of this issue (p. 675).

MERCHANT TAYLORS' COMPANY.

IN 1903 the Merchant Taylors' Company, the successor of the Guild of Merchant Taylors of the Fraternity of St. John the Baptist in the City of London, admitted Lord Lister to its honorary freedom, in recognition of the long and valuable services rendered by him to the country, and particularly to surgery, by the discovery and application of the antiseptic treatment. It was appropriate, therefore, that the Company should take a share in the celebrations of this week. On Tuesday evening it entertained a large company to dinner in its beautiful hall, which still stands on the site in Threadneedle Street which the Guild acquired in 1347. After the Master, Mr. A. L. F. Cook, had given the loyal toasts, he proposed the health of the Lord Mayor, Sir Rowland Blades, Bt., M.P., who, in replying, spoke warmly and with knowledge of the great services Lister had rendered to surgery. The "Memory of Lord Lister," briefly proposed by the Master, was drunk in silence. The Earl of Crawford and Balcarres, K.T., F.R.S., then proposed the toast of "The Delegates," who, he said, had come from all parts of the world to recognize Lister's great work in physiology and pathology. Within the lifetime of many of them, he continued, there had been very great progress, both in medical science and the philosophy of the hospital. All present were proud to belong to an age which had witnessed marvels in the relief of human suffering and their diffusion throughout the world. Speaking for the public, he would say that it wished the surgeons, physicians, and pathologists who were concerned in that progress all success in the future. The toast was acknowledged by Professor J. Nicolaysen of Oslo (Norway), who, after some general observations, said that Lister's methods had been an inspiration to all in all countries and had stood the test of the war. Dr. Irving H. Cameron, Emeritus Professor of Surgery in the University of Toronto, also responded; he said that the cogency of Lister's observations and the theory founded upon them had received early recognition in Canada. Finally, Sir John Rose Bradford, President of the Royal College of Physicians of London, and chairman of the executive committee by which the arrangements for the celebration had been so well made, proposed the toast of "The Master." The occasion, he said, had received recognition at all hands: first by the King, who had received the delegates on Monday morning; then, that morning, by the large medical audience which assembled in the Hall of the British Medical Association to witness the reception of the delegates by the Prime Minister; and next by the chief magistrate of the City of London, who had addressed the company that evening in the ancient and beautiful hall of one of the oldest and greatest of the city companies. The Master, in a brief reply, expressed his own pleasure and that of the Company he represented in being able to pay a tribute to Lord Lister, who had been one of its most distinguished members. Among the company, in addition to those whose names have been mentioned above, were many representatives of science, medicine, and literature, including, in addition to the foreign delegates, the Minister of Health (Mr. Neville Chamberlain), the President of the Royal Society (Sir E. Rutherford, O.M.), the President of the British Medical Association, Sir Watson Cheyne, Sir Berkeley Moynihan, Dr. Andrew Fullerton (President of the Royal College of Surgeons in Ireland), Sir Arthur Keith, Sir George Makins, Sir Charles Sherrington, Sir Walter Fletcher, Professor G. M. Robertson (President of the Royal College of Physicians, Edinburgh), Dr. R. M. Buchanan (President of the Royal Faculty of Physicians and Surgeons of Glasgow), Sir William Taylor (Dublin), the Bishop of Birmingham, the Lord Provost of Glasgow, Sir Edward Gosse, Sir George Frampton, R.A., Professor E. H.

Starling, Sir R. Havelock Charles, Major-General J. B. Smith (I.M.S.), Sir David Prain (Treasurer of the Royal Society), Sir Richard Gregory (editor of *Nature*), Sir James Berry (President of the Royal Society of Medicine), Sir Thomas Barlow, Bt., M.D., Professor J. Marnoch (Aberdeen), Professor A. W. Sheen (Cardiff), Sir George Newman, and Professor Elliot Smith.

MEMORIAL SERVICE IN WESTMINSTER ABBEY.

ADDRESS BY THE BISHOP OF BIRMINGHAM.

THE memorial service in Westminster Abbey on Wednesday morning, at which an address was given by the Lord Bishop of Birmingham (Right Rev. E. W. Barnes, F.R.S.) was attended by the official delegates, most of whom wore academic costume and were accommodated in the nave, and the rest of the building was filled in every part by members of the general public. Viscount Hampden attended as the representative of H.M. the King.

The service included Handel's anthem, "When the ear heard him," which had been rendered fifteen years previously on the occasion of Lister's funeral. The Prime Minister had quoted the words of this anthem in his speech on the previous day. A special collect was said for the Presidents, Councils, and Fellows of the Royal Societies, and the lesson, read by the Dean of Westminster, was from St. Luke ix, 19-23, in which is described Christ's commendation of His miracles of healing to John the Baptist as evidence of His divine mission.

The BISHOP OF BIRMINGHAM said that they had met in the Abbey, where but for his own desire Lister might have been buried, to give thanks to God for the benefit which this great surgeon had conferred upon humanity. That was not the occasion on which to discuss the technical aspects of his discoveries or to delimit the range of his genius. Such a task was more rightly undertaken by members of Lister's own profession. He was more concerned to commemorate the personal qualities of the man, the religious principles which fortified his character and guided his actions, the patient enthusiasm which served his genius, and especially the inestimable value to humanity of his life-work.

The steady persistence with which Lister pursued a single great aim throughout his career was remarkable. As a medical student at University College, London, he read a paper on hospital gangrene; and at the end of his professional life he was still endeavouring to perfect the details of the great aseptic method of treatment which had revolutionized modern surgery. Lesser men might have been intoxicated by fame, but Lister preserved a humility which was singularly attractive; he sought truth patiently; he was ever willing to examine the new theories and methods which might lead him to modify his earlier conclusions; he had, in a word, the true scientific spirit, and with it the insight of genius. Whence came his quiet pertinacity, his steady trustworthiness? He owed much to his Quaker ancestry. It was not fanciful to see in the practical ability of his father and the gifted imagination of his mother the sources of some of his own remarkable qualities. In his early home life, with its traditions of self-discipline and high endeavour, there were influences which made his character the worthy servant of his mental gifts. He combined piety, gravity, reverence, and hopefulness; he was pure-minded and conscientious, convinced of the power of goodness, and a loyal servant of truth; and he who could show such qualities and preserve such an attitude of mind was not far from the Kingdom of God.

The preacher then passed in brief review the principal features of Lister's career, touching also upon the discovery of chloroform by Simpson. Even after Simpson the operation table remained as dangerous as the field of battle until Lister worked out his great discovery. He was led to his experimental use of carbolic acid as a dressing for wounds by a study of Pasteur's work. To praise Lister was in no respect to belittle Pasteur. By 1865 the idea of antiseptic treatment seemed to have shaped itself in Lister's mind. The scientific principle which guided him was of transcendent importance. The chemical substances he used were but a means to an end, and had now to some extent gone out of use; but the change from antisepsis to asepsis was an improvement in technique rather than an alteration in principle. From Germany, subsequent to the Franco-Prussian war, came a new type of hospital cleanliness and method which made its way to England, and when it arrived in this country there were some who, eagerly embracing the new methods, excused their indifference to Lister's teaching by proclaiming the inferiority of antisepsis to asepsis. But on the Continent the leaders of medical thought and progress had no hesitation in assigning to Lister the praises which he merited. London was for a time apathetic. Once again it appeared that a prophet was not without honour save in his own country. But after the triumphant welcome and enthusiastic homage which Lister received in 1879 at the International Medical Congress in Amsterdam his fame was secure. Thenceforth to disparage Lister or to belittle his achievements was to confess oneself prejudiced and ignorant. Of the new era Lister was hero and pioneer. It might with truth be said that he made surgery safe for humanity. Henceforth he was to receive almost every honour the gratitude of society or the esteem of men of science could confer.

"When we think of such a discovery as we associate with the name of Lister," said Dr. Barnes in conclusion, "we wonder how many more such discoveries shall yet be made by humanity. Thanks to Lister, the surgeon and the physiologist can now work hand in hand. The origin of pathological changes can be investigated. Shall we in the end discover how we may prevent the onset of disease? The question cannot be answered, but we need not hesitate to affirm that man's future triumphs in the war against disease will surpass the victories already won. Sometimes when we speculate on the future of humanity we think of the highly evolved forms of life that lorded this earth in past ages and disappeared. Why did they disappear? Probably, I suppose, minute organisms swept them away. Either the virulence of such organisms increased, or the animals attacked lost their power of resistance. Is such an end to be the fate of humanity? Many a zoologist would say so. Yet man differs from all other animals that have come from earth's teeming womb in the characteristic development of the powers of his mind, in some quality of personality and survival value different from that of the lower animals. Is it possible that by virtue of those same mental powers with which he is endowed man will in the end conquer disease and pain, and thus prepare the way for the Kingdom of God upon earth? Will physical and moral victories combine to make human life nearer to human hopes and dreams? None can say. We build for an unknown future. Yet the achievements of the leaders of human progress give substance to our hopes. We thank God for the master builders whom He raises up. We believe that there is something in their work which will never perish. To-day we thank God for Lister, for the relief from pain and disease which he brought to mankind; and no less do we give thanks for his single-minded devotion to science, which will inspire others following his work for the welfare of the human race." After the sermon the choir and congregation joined with fervour in the hymn "Now thank we all our God," the English version of Martin Rinckart's fine song of praise.

Although it was not found possible to arrange for the Council of the British Medical Association to attend the Abbey as a body, the President, Mr. R. G. Hogarth, was present as representative of the Association, and some other members of Council attended in their individual capacities. On behalf of the Association Mr. Hogarth placed a beautiful wreath beneath the medallion of Lister.

LISTER MEETING OF THE ROYAL SOCIETY.

THE THREE DISCOURSES.

THE Barnes Hall of the Royal Society of Medicine was crowded by the Fellows of the Royal Society and their friends, who met together on Wednesday afternoon to listen to the three discourses with which this issue opens. No orators could have been selected so well fitted—none certainly more fitted—for the tasks assigned to them. It would be difficult to ascribe to any one of the three

ascendancy over his fellow speakers. The discourses of Sir Charles Sherrington and Professor Bulloch were both of great literary merit as well as of high scientific value, and Sir Berkeley Moynihan concluded his discourse with a peroration couched in beautiful English and inspired by the brightest hopes for the future of medicine and surgery.

The President of the Royal Society, Sir Ernest Rutherford, in introducing the speakers, said that he would point out, and indeed emphasize, that Lister's establishment of antiseptic surgery was one of the most striking examples of the power of the scientific methods in advancing knowledge and also one of the most useful illustrations of the mental and moral qualities required to wrest secrets from nature. Professor Nicolaysen, on the previous evening, had said that the idea on which Lister worked did not in a sense come as a haphazard inspiration. Lister, even in his undergraduate days, had been greatly interested in the subject of hospital gangrene, and later, when he became professor of surgery, he continued to give a great deal of time and thought to experiment on the problem that impressed him—namely, inflammation and suppuration and the methods of controlling them. After many years of patient thought and experiment there came the illuminating results. Starting from Pasteur's work on micro-organisms as the cause of fermentation, Lister at once saw the possibility of the theory that the cause of suppuration was the introduction of some unknown micro-organism, and guided by that idea he subsequently developed his wonderful method. While he continued his investigations to prove the truth of this hypothesis he at the same time developed the technical methods to ensure success. In Lister there was the most unusual combination of a man of philosophic outlook endowed with great power of experiment and having the direct command of technique which was essential if his method was to be successful.

At the end of the discourses Sir Ernest Rutherford said that, like himself, the audience, he felt sure, had never passed a more interesting and enthralling afternoon. He thanked Sir Charles Sherrington, a great leader in physiology, for his address. The audience had been fortunate, too, in having Professor Bulloch, who knew Lister well owing to the position he held at the Lister Institute in the early days; the audience were grateful for the way in which he had treated the subject. What, he asked, could he say of Sir Berkeley Moynihan, of his eloquent address, and of the great knowledge he displayed of the possibilities and limitations of the art in which he excelled so much? On behalf of all present he desired to thank the three orators for their addresses.

THE ROYAL SOCIETY'S CONVERSAZIONE.

THE Royal Society held a conversazione on Wednesday evening (April 6th), which was attended by a very large number of guests, who had an opportunity of seeing many things of interest, old and new, for the Society displayed a selection from its muniment room. Of the new things the most striking was the cinematograph film shown by Dr. R. G. Canti of St. Bartholomew's Hospital. Two audiences witnessed in this film the behaviour of the living cells cultivated *in vitro*. The photographs were taken from connective tissue (periosteum of the chick) and cancer tissue (Jensen's rat sarcoma). The method is being employed to investigate the effect of irradiation on tissue cells. The pictures showed the migration of the cells from the original implant, the intracellular structures, and mitotic division. Dr. Canti described the method employed for the production of the film, to which great labour had gone. Exhibits from the Strangeways Research Hospital at Cambridge further illustrated work of this nature. Dr. J. A. Andrews and Dr. Honor B. Fell demonstrated the method of dark illumination of tissue cultures *in vitro*. The intracellular structures were well shown, and the active movements of the cells grown from malignant tissues could be compared with the slow movements of fibroblasts. Dr. Canti and Dr. Malcolm Donaldson illustrated the effect of radium on mitosis by tissue cultures exposed to the gamma rays of radium in a lead incubator. The earliest observable effect is the cessation of mitosis; this is followed by the appearance of "breaking down" cells, arrest of outwandering, and the death of the tissue. Dr. F. G. Spear and Miss D. Strangeways exhibited diagrams illustrating the quantitative effect of radium irradiation on mitosis of cells grown *in vitro*. It appeared that in order to obtain the same biological effect with a small intensity of irradiation as with a large one, it is necessary to increase the time of exposure more than would be expected by physical considerations. The apparatus used for these investigations was shown. Dr. Fell also exhibited stained microscopic specimens of the cytology of Jensen's rat sarcoma cultivated *in vitro*. Sir Almroth Wright with Mr. Alexander Fleming, F.R.C.S., and Dr. Leonard Colebrook demonstrated the methods of studying the defensive powers of the organism and testing the effect of therapeutic agents. It was pointed out that serum fails to furnish cultures when implanted with ordinary (non-serophytic) microbes, and exerts a bactericidal effect upon some of them; on the other hand, it furnishes a favourable culture medium for a special class of microbes (serophytic microbes), which are killed by blood containing leucocytes. The demonstration included an account of the agencies which can be employed to reinforce or replace the bactericidal powers of the organism; these were: first, immunization with vaccines by the administration of chemical agents which increase the number of leucocytes, and light treatment; secondly, the use of antiseptics which destroy the bactericidal power of the leucocytes, blood fluids, and blood; and thirdly, chemotherapeutical agents, which can confer bactericidal power for serophytes upon the blood fluids, and may, when the dose administered is tolerated by the leucocytes, increase the bactericidal power of the blood. A new type of electric discharge was shown by the British Thomson-Houston Company; Dr. Langmuir and his fellow workers had discovered that when into an arc produced in a hot cathode discharge tube tungsten vapour was introduced, special phenomena appeared. The British Museum had a display of oceanic angler fishes by Mr. C. Tate Regan, F.R.S., and of mimicry in insects by Mr. G. J. Arrow. Among the exhibits of historical interest from the collection of the Royal Society itself were the mace of the Society, presented to it by Charles II in 1663; the Charter Book of the Society containing the signatures of founder, patrons, and Fellows from 1662 to the present day; the official certificate of candidature for Fellowship of the Royal Society in favour of Lord Lister (1860); and the medals of the Society, including the Copley, awarded to Lister in 1902, and the Royal, given to him in 1885. Among other exhibits of this order were copies of telescopes made and used by Galileo; a set of Napier's bones, either used by Napier of Merchiston or early copies; a line-dividing engine made by James Watt in 1774; Joule's original electro-magnet and his water friction apparatus for determining the mechanical equivalent of heat; and, bringing things down almost to the present day, a set of apparatus illustrating the development of the microphone.

COMMEMORATION AT LISTER'S BIRTHPLACE.

UPTON HOUSE at Upton in Essex, where Joseph Lister was born on April 5th, 1827, is now the vicarage of St. Peter's, Upton Cross, in the County Borough of West Ham, and on the afternoon of Tuesday, April 5th, 1927, a commemoration service was held in the church.

The procession, headed by choir and clergy, which formed at the vicarage, included the Lord Provost of Glasgow, the mayors of West Ham and other Essex boroughs, with their town clerks and medical officers of health, the chairmen of neighbouring urban district councils, and justices of the peace, the chairman of the Essex County Council Public Health Committee, and the county medical officer of health, together with many members of the medical profession and representatives of the hospitals in the district. The service was taken by the Vicar of St. Peter's, the Rev. A. J. Parry, assisted by the Vicar of West Ham; the Rev. R. Rowntree Clifford (President of the West Ham Free Church Council) read the lesson from Ecclesiasticus xxxviii. The sermon was preached by the Right Rev. Guy Warman, D.D., Bishop of Chelmsford, and Sir Humphry Rolleston, Bt., K.C.B., Regius Professor of Physic in the University of Cambridge, delivered an address.

The BISHOP OF CHELMSFORD described Lister as a teacher of hope and an inspirer of love for the age in which he lived. He was also a man of faith; his faith in the discovery he had made was part of a greater faith, for his religion was part of the working apparatus of his life. Lister was also a man of persistent toil, and he found life hard work; with him, as with others, the reward of a thing well done was to have done it.

Sir HUMPHRY ROLLESTON, after recalling briefly the parentage of Lister and the early influences that surrounded him, said that the two great events in the history of surgery were the introduction in 1846 of anæsthetics, which made surgery possible, and had been called "the death of pain," and the discovery of the antiseptic and aseptic method, dating from 1867, which made surgery safe for humanity, and might, in like manner, be termed "the death of infection." Lister had long been thinking and preparing how to obviate the risks of the diseases which attacked patients after operations, but the discovery in 1864 that germs of micro-organisms caused putrefaction was made by the great Louis Pasteur. Most surgeons, if they heard of Pasteur's researches, would have been mildly interested in them, but Lister was able to grasp their significance, and henceforth devoted his life to applying this principle to the prevention of post-operative infection. His brilliant imagination, philosophic insight, untiring industry, and unflinching courage overcame the antagonism, not to mention ridicule, that his life-saving work provoked, and he finished his task. In 1867 Lister published his first papers on antiseptic surgery, and from that time he continued by most careful and indomitable research to improve the methods. The history of surgery had indeed been divided into two periods—that before and that after Lister's methods became adopted. Before his discovery as few operations as possible were done because of the risk that they would be followed by erysipelas, blood poisoning, pyæmia, hospital gangrene, tetanus, and death; abdominal operations, such as are so constantly done now for appendicitis, were practically unknown; to open a large abscess was almost certainly to sign the patient's death warrant. Hospitals, indeed, were spoken of as "houses of death." Lister, who was Professor of Surgery in Glasgow from 1860 to 1869, became Professor of Clinical Surgery in Edinburgh, and there continued to practise, preach, and perfect the doctrine of antiseptic surgery. Like most great advances and reforms, this life-saving discovery met with much opposition and criticism, and in order to overcome these adverse influences, and to spread the knowledge of the correct method of carrying out the antiseptic treatment, he accepted in 1877, when 50 years of age, an invitation to be Professor of Clinical Surgery in King's College, London, for, be it said with regret, his native city was the stronghold of antagonism. His London life fell into two almost equal periods: From 1877 to 1893 he was a busy hospital surgeon, gradually convincing all of the inestimable value of the antiseptic methods; in 1893 his retirement from the hospital, on account of age, and the sudden death of his devoted wife, leaving him a childless widower, entirely altered his life. Henceforth, with rare nobility of character, he devoted himself to public duties until his death on February 10th, 1912.

"Like Pasteur," said Sir Humphry Rolleston in conclusion, "and more fortunate than many reformers and pioneers, Lister lived to see his work bear fruit exceedingly, and died full of years and loaded with honours from all countries; but it is as the greatest material benefactor of the human race, who made surgery safe, and thereby did more than any other man to prevent suffering and save life, that we regard him with deep gratitude and thankfulness."

SOME OTHER CENTENARY CELEBRATIONS.

WE have received brief notes of celebrations of the centenary of Lord Lister from other places, and we feel sure that there are more to come. We are indebted to Professor I. H. Cameron for the information that on Tuesday last Dr. William James Mayo, surgeon and chief of the staff of the clinic which bears that name, was to deliver a lecture in Toronto, in which he proposed to commemorate the centenary of Lister and to discuss the relation of the basic sciences to surgery. Dr. Donald C. Balfour, who graduated at the University of Toronto in 1914, and is now specialist in the surgery of the stomach at the Mayo Clinic, recently endowed an annual lectureship, and this was the first of the series.

At Carlisle last week Dr. Norman Maclaren, surgeon to the Cumberland Infirmary, delivered an address to the Rotary Club, in the course of which he dealt with the achievements of Lord Lister, who, he said, belonged to a family settled in Bingley in Yorkshire. His mother, who was born at Maryport, Cumberland, was the daughter of Anthony Harris, a member of a family which came from the Allerdale Ward, about the lower reaches of the Cumberland Derwent. After describing how before Lister's great discovery the surgeon was dogged and hampered by sepsis, Dr. Maclaren recalled that Lister had himself stated how in 1864 he had been much struck by reading an account of the remarkable effects produced by carbolic acid on the sewage of Carlisle, a very small proportion not only preventing all odour from the lands irrigated, but destroying the parasites which commonly infested cattle fed upon such pastures. Lister visited Carlisle as the guest of Dr. Robert Elliot, the first medical officer of health of the city, by whom he was informed that in 1843 George Stephenson had made reports on the disposal of the city's sewage to the mayor and corporation, and in 1849 Robert Rawlinson to the General Board of Health. The use of carbolic acid for disinfection of the sewage was already working with some success in 1864. It was, Dr. Maclaren said, greatly to the credit of the municipality of Carlisle that it should have so early given attention to the disposal of sewage and so incidentally suggested to Lister a method of applying the principles he had evolved for the treatment of wounds, principles which had proved of such inestimable benefit to mankind.

England and Wales.

THE GENERAL INFIRMARY AT LEEDS.

THE one hundred and fifty-ninth annual report of the Leeds Infirmary was presented to a meeting of the governors held under the chairmanship of the honorary treasurer, Mr. T. F. Braime, on March 30th. Each year it is recorded that the Infirmary is working at full pressure, and yet each year some increase is noted. The total number of in-patients admitted during 1926 was 12,688, as against 12,083 during 1925. This is accounted for by a considerable increase in the medical cases, and especially in the aural department, and an increase in the number of accidents admitted, many of these being motor accidents. In the out-patient department the increase is very much greater, for here the limitations imposed by space do not tell to any extent. In the radiographic department the number of new patients seen was 11,752, as against 11,221 in 1925. In the electro-therapeutic department the new patients have gone up from 1,125 to 2,012, and the attendances from 33,184 to the enormous total of 59,222. An examination of these and of other figures brings it home to the mind that the voluntary hospital accommodation provided by Leeds is inadequate when viewed in relation with the large area it serves, with its importance as a medical centre, and with the fact that the Infirmary is the only general hospital in Leeds. If any doubt existed as to this, an inspection of the long waiting list would convince the most sceptical. The great necessity for an increase in the accommodation was emphasized by the chairman at the meeting, and the question of providing paying wards was mentioned and will engage the early attention of the board. Those who are sanguine can see on the vacant space within the grounds of the infirmary two new three-storied blocks containing about one hundred beds each, one at least of which would be devoted to paying patients and would be self-supporting. In this way a great need would be in some measure met and the pressure on the general wards lessened. There is no doubt that at present a large number of beds are occupied by those who certainly

cannot afford the great expense involved by medical and surgical treatment in a nursing home, but who ought not to be treated gratuitously, and there are many of them who do not wish to be so treated. Not only in Leeds but all over the country this is a crying need of the times. The financial condition of the Infirmary is causing the board great anxiety. Compared with 1914 the expenditure has more than doubled, while the regular income has not increased to anything like the same degree. This is not the place to enter into details of finance, but it is clear that the time has come when a great effort must be made to increase the regular income of the Infirmary and to provide the necessary accommodation for the efficient carrying on of the work. The unofficial union of the Infirmary with the University has been strengthened during the year. A site has been provided by the Infirmary for the building of a properly equipped dental hospital and school. The University, of course, confers degrees and grants diplomas in dentistry, and the school of dentistry has developed on sound lines since it was started some twenty-five years ago. At first it found good accommodation in the newly erected buildings of the public dispensary, but more recently it has required to seek temporary new quarters. These have been provided by the Infirmary, which placed at the disposal of the dental board the large out-patient room, which has been fitted up, and which fills the purpose excellently, as a temporary place of accommodation. The new dental hospital is approaching completion, and the large amount of space which will be set free in the Infirmary by the transference of the dental work to its own premises will, it is hoped, be utilized for the development of the department for massage and therapeutic exercises. Another very important development, which it is hoped will soon be completed, is the instructional block at the Infirmary. In 1922 (see JOURNAL for January 7th, p. 21, and May 27th, p. 844) some account was given of the methods of teaching in medicine and surgery and of the alterations which it was deemed wise to carry out in view of the report of Sir George Newman on medical education. These involved the appointment by the University of three whole-time tutors and certain other officers, and it was pointed out that a great advance would be made by the provision of a properly equipped instructional block. This has been in part secured, and it is hoped that the University will, in the interests of the teaching for which it is responsible, complete this, and so secure for Leeds what it is believed will form one of the best teaching departments in the country. The fuller development of the skin department is referred to elsewhere (see p. 679).

THE L.C.C. AND PAPWORTH COLONY.

The London County Council a few weeks ago instructed its Public Health Committee to report on the Papworth Institution (or the Cambridgeshire Tuberculosis Colony), with a view to the possibility of the Council establishing a similar institution under its own control. Dr. Noel Bardswell accordingly visited the colony, and his report, with the conclusions of the committee, was submitted to the Council on April 5th. Papworth comprises both a sanatorium and an industrial settlement, but the relatively small number of patients who can be absorbed annually as permanent settlers is a limiting feature of this kind of institution which has to be taken into account. Since Papworth was opened about ten years ago 193 patients have been sent there for treatment under the Council's scheme, but of this number only 20, on completing treatment, were transferred into the settlement. One of these has since died, another has been readmitted to the sanatorium, and the remaining 18 are still resident and employed. The total number of settlers is 160. Every patient admitted to Papworth and every one of the 200 sanatorium patients to-day working in the various workshops is a potential settler, but few have in fact any prospect of becoming permanent residents. Papworth, as a complete entity, with its sanatorium, industries, estate, and settlement, at present approximately pays its way, but no charge is made for interest upon the capital sunk in the undertaking; a public authority running a similar institution would be in a much less advantageous position as there would be interest and redemption charges to meet. Institutions combining treatment and training were undertaken, in the first instance at all events, for the benefit of tuberculous ex-service men, and a considerable proportion of the capital expenditure was obtained from voluntary contributions subscribed for their benefit. An ex-service man, by reason of his disability pension and the provision made for his dependants, is in a favourable position for taking full advantage of any portion of the tuberculosis scheme, and the absence of these considerations in the case of civilians places the problem on a different footing. The conclusion of the Public Health Committee of the Council is that every credit is due to the medical superintendent of Papworth and those associated with him for their successful efforts, and that institutions on the Papworth pattern are suitable objects for philanthropic interest and support, but that such enterprises cannot offer a solution of the problem of providing suitable employment or occupation for urban tuberculous persons after discharge from sanatoriums. It is not prepared, therefore, to advise the establishment of a similar institution by the Council.

THE PRINCE OF WALES ON MENTAL AFTER-CARE.

Wordiness at public gatherings is a frequent matter of lament, but the extreme in the opposite direction was surely reached at the Mansion House of all places, that home of national oratory, on Thursday of last week at the meeting to further the work of the Mental After-Care Association. The Prince of Wales, who is the patron of the society, was present, the platform was occupied by a number of distinguished mental specialists and social workers, the Lord Mayor and Sheriffs were the hosts of the occasion, and a gathering of several hundreds of people were in their places in the Egyptian Hall for half an hour before the meeting was timed to begin. Yet the whole proceedings, which included four speeches, occupied barely ten minutes, and the meeting was over before some realized that it had begun. The Prince said that, although the association was founded nearly half a century ago, it was only within the last ten years or so that the general public had come to realize the great importance of its work. One of the legacies of the war was the care of a large number of men whose disability was not physical but mental. The urgent need of helping such men had led the medical profession to speed up its study of mental infirmity generally, so that this particular branch of medical science had made very great progress, and had brought home to the general public the fact that mental trouble was just as much a disease as any of the more familiar physical illnesses. No one knew better than himself with what wonderful generosity the public always responded to an appeal for the physically infirm, but that day, as patron of the association, he asked for a similar measure of generosity for those mentally afflicted. For forty-eight years the association had carried on its work in the face of many difficulties. Many patients had been restored to normal health when, but for the association, they would have remained always a charge on their relations or on the State. The Prince summarized briefly the objects for which the association worked: it facilitated the discharge of patients from institutions by acting as an intermediary between the hospital and the patient's home or by offering accommodation in a cottage home when the friends of the patient were unable to receive him; it consolidated recovery by providing for convalescence at the seaside or in the country, or by helping the sufferers to obtain suitable employment, and, finally, it prevented relapses by the personal supervision of specialists or by the provision of such extra nourishment or surgical appliances as the circumstances might require. The association was often also able to give help to prevent threatened cases of mental infirmity developing. He assured the association of his warmest sympathy and his wishes for the success of the appeal on behalf of the funds of the association which had lately been made to the public. Dr. R. Percy Smith announced that as a result of this special appeal the amount to hand was £8,436; a large contribution to this total was due to a broadcast talk on behalf of the association. The Lord Mayor proposed a

vote of thanks to the Prince of Wales, and this having been seconded by Sir Charles Wakefield, and carried with much acclamation, the proceedings terminated.

KENT COUNTY OPHTHALMIC AND AURAL HOSPITAL.

Following the opening of the new aural wing of the Kent County Ophthalmic Hospital at Maidstone by Lady Harris, it has been decided to change the name of this institution to the Kent County Ophthalmic and Aural Hospital. The new wing, which has been erected at a cost of upwards of £10,000, includes a children's ward, with accommodation for eight patients, a single private ward, and an operating theatre with sterilizing and anaesthetic rooms. Two consulting rooms have been provided on the ground floor, with good waiting rooms and dispensary accommodation; there is also a dark-room for examinations, a casualty and emergency operating room, a main sterilizing and isolation room, and a canteen. The extension increases the number of beds of the institution to seventy-two, and greatly improves the facilities for dealing with out-patients. Mr. J. Aldington Gibb, senior honorary aural surgeon, gave a brief account of the history of the hospital since its foundation eighty years ago, and stated that over 15,000 patients required treatment each year. In 1926 more than 1,000 operations had been performed. At the annual meeting of the hospital held before the opening ceremony, it was announced that the number of in-patients during 1926 was 913, the number of new ophthalmic out-patients 5,201, and of new aural cases 3,814; in addition 1,091 casualty cases had been dealt with during the year. Lord Harris referred to the very satisfactory result of the work of the Weekly Subscribers' Fund, which had made the receipts for the hospital larger than those of 1925, despite substantial decrease in the annual subscriptions and donations. He added that the hospital set an example to other institutions in the country in the success it had achieved by arranging for a wider distribution of its appeal, and by extending to a greatly increased number of people the benefits of its services in return for a small subscription.

Scotland.

SCOTTISH UNIVERSITIES SEAT.

THE Unionist associations of all the four Scottish Universities have unanimously adopted Mr. John Buchan, the well known novelist and writer on historical subjects, as their candidate for the seat in Parliament rendered vacant by the death of Sir Henry Craik. Mr. Buchan is a graduate of Glasgow and Oxford Universities, and acted as private secretary to Lord Milner in South Africa. The two present members are Sir George Berry and Mr. D. M. Cowan. The Liberal organization has decided not to nominate officially any Liberal candidate, and Sir John Collie has now announced that in order to avoid a three-cornered contest he has withdrawn his name. Action has been taken by the Scottish Executive of the Independent Labour party, Glasgow University Labour Club, and the Socialist Teachers' Society to nominate a Socialist candidate for the vacancy. The name of Mr. H. N. Brailsford has been mentioned, but he is said at the present time to be in Russia and unlikely to return to this country for some time. Other proposed Socialist and Communist candidates include the names of a Glasgow teacher and a Glasgow doctor. A meeting is to be held shortly for the adoption of a candidate.

MUIRHEAD CHAIR OF OBSTETRICS AND GYNAECOLOGY, GLASGOW.

The Board of Curators has appointed Dr. James Hendry, M.A., B.Sc., M.D., F.R.F.P.S.G., to the Muirhead chair of obstetrics and gynaecology in Glasgow University, rendered vacant by the appointment of Dr. John M. Munro Kerr to the Regius chair of midwifery. Dr. Hendry, who was born in 1886, is a graduate in arts, science, and medicine of the University of Glasgow. Immediately after graduation he visited gynaecological clinics at Berlin, Leipzig, Munich, and Vienna, and spent three months in the Cliniquo Tarnier at Paris. Returning to Glasgow in 1914, he was appointed second assistant to the Muirhead professor and dispensary gynaecologist to Glasgow Royal Infirmary. Among more recent appointments held by him were those of physician to the Royal Maternity and Women's Hospital at Glasgow, assistant gynaecologist to the Royal Infirmary, and consulting obstetrician to the Lock Hospital, Glasgow. In 1916 he proceeded to service in France. He is the joint author with Professor Munro Kerr of *Notes on Midwifery*, and with Professor Munro Kerr, Dr. James Haig Ferguson, and Dr. James Young of a *Combined Textbook on Obstetrics and Gynaecology*. He has also contributed numerous articles to current medical literature.

GLASGOW ROYAL CANCER HOSPITAL.

At the annual meeting of the Glasgow Cancer Hospital on March 20th, Dr. Buchanan pointed out that solution of the problem regarding cancer would depend, not only on the physician and surgeon, but largely on the co-operation of the public. While ordinary bacterial diseases were of the nature of an accident, cancer was more subtle and took its origin most frequently as the result of some long-continued irritation. Its cure at the present time was dependent on early treatment, and it was here that the co-operation of the public would be of essential help, not only to the individual but to preventive medicine, if persons over 30 years of age were encouraged to submit themselves to annual examination. It was not yet possible to assign any one cause to cancer, although evidence existed in regard to some cancers in favour of their being due to an organism. He thought that the people of Glasgow owed a debt of gratitude to the directors and staff for promoting the research side of the institution's activities. Professor Archibald Young said that research required money and plenty of it, and it lay with the public to see that this research was not stinted or checked for lack of funds. Sir George T. Beatson also spoke, and agreed that irritations seemed to be the common basis upon which researchers into this malady were now working. A biochemical change appeared to be the cause.

ABERDEEN INFIRMARY SCHEME.

Only a small part of the Royal Infirmary and Aberdeen joint hospitals scheme has so far been begun; this consists of the erection of buildings for the new Hospital for Sick Children, towards which £100,000 has been secured. The whole scheme aims at raising a total sum of £400,000, of which £300,000 is intended for the erection of the new infirmary, and £100,000 to increase the endowment fund. The Lord Provost has already been promised £200,000 for the Royal Infirmary, of which £100,000 was contributed by four friends of the scheme. Various donations, ranging from £1,000 to £10,000, have also been intimated, and the subscription list includes a sum of £11,200 from the Cruikshank Trust and £30,000 from the Miss Fraser Trust. The Lord Provost, speaking recently at a meeting of the Royal Hospital for Sick Children, said that the Royal Infirmary was as much in need of extension and ought to be built in the neighbourhood of the Children's Hospital. He thought that it was highly desirable that the Royal Hospital for Sick Children, the Royal Infirmary, the University pathological department, and, he trusted, the city's public health department, should all be built together at Forresterhill, and negotiations towards that end were progressing satisfactorily.

WORK AMONG THE DEAF AND DUMB.

At the annual meeting of subscribers of the Edinburgh Deaf and Dumb Benevolent Society, on March 29th, the Lord Provost Stevenson, in moving the adoption of the annual report, said that for eighty-six years the society had been carrying on its work with increasing activity and efficiency. In the past year it had spent £670 in relieving deserving cases. The financial position was also satisfactory, and it had a small surplus on the year's working. The society was about to purchase an ideal spot at Hawthornden which would provide a rest home for beneficiaries.

Correspondence.

CERTIFICATION OF THE INSANE.

SIR,—Your leading article *re* the Hume-Spry case will doubtless be widely read, and medical men will be grateful for your clearly expressed view of the difficulties which beset any who, in the course of their practice, are called upon to certify a patient as insane and a fit and proper person for care and treatment.

I do not think I am overstating when I say that, in this special case, several leading articles might be written on various aspects of the evidence given before the court during the fifteen days of the trial, but as a prosecution is threatened against the plaintiff, many common-sense opinions might be taboo.

There is, however, one aspect of the case upon which you do make a short observation, but which, to my mind, should have been much more emphasized: that is the action under Section 13 of the Lunacy Act of 1890. Under this section, upon information being given to a relieving officer or the police that a person of unsound mind is likely to be dangerous to himself or others and is not under proper care or control, either of these officials informs a magistrate, who, if he thinks it necessary, makes an order for two medical men to visit, examine, and, if necessary, certify such person, and, presuming he is satisfied that these certificates prove that the patient is insane and needs care and treatment, he makes the order. On the latest ruling of the Law Lords, medical men so acting under an order by a magistrate cannot be proceeded against and automatically the action is stopped.

Had Dr. Percy Smith recognized his possible danger in this specific case and refused to examine the patient or certify, except under an order by a magistrate as described in Section 13, I take it that this case would never have been heard of. It is interesting to note that the advice to act under this section was given to Dr. Dill by the relieving officer, as stated in the case of de Freyville *v.* Dill.

Unfortunately, the committee of medical men appointed by the British Medical Association to watch this 1890 Lunacy Act, upon which I sat, overlooked part of Section 13—namely, that persons so certified have to be sent to the county asylum, from which, of course, they can subsequently be transferred to a registered hospital or a private mental home or single care.

It has long been brought home to me that this ruling is pernicious and prevents the section being more used. In my suggestions to the Royal Commission on Lunacy I pointed out that, if the relatives of the patient have arranged for some registered hospital or private mental hospital to receive the patient, he or she should be taken direct to such institution and not to the county asylum.

In more than one case recently I have been able, by sane, reasoned persuasion, to get the magistrate to make an order direct to the place chosen by the relatives, on the ground that a county asylum would not be a suitable place for the specific case.

I had hoped that the Royal Commission on Lunacy would have taken much more notice of very urgent alterations in many sections of the present Lunacy Act—alterations which would have greatly benefited the insane and all those concerned with their care; and I was very disappointed when, on reading their invaluable report, I found these very necessary alterations were not even commented on.

I hope the British Medical Association will do all in its power to get this 13th Section altered as suggested, for I feel confident that, by utilizing this section, many of these legal actions would never come into being.

In concluding this letter, may I touch upon an inconsistency in the legal mind which, in both these recent cases, has come vividly before me, and, to my knowledge, before the minds of many of those called by the press "the man in the street"? Have not these judges trying these cases quietly swallowed and noted down evidence, as proof of an unsound mind, which if brought before them as a defence in a criminal case they would, metaphorically speaking, have laughed out of court.—I am, etc.,

Bournemouth, April 3rd. LIONEL A. WEATHERLY, M.D.

SIR,—While agreeing entirely with your leading article on this subject, I believe that many of the profession will think the suggested remedies insufficient, and that it is time the profession took a very definite and strong line to obtain complete protection for the medical man who undertakes the unpleasant duty of certifying. Of all the persons necessarily concerned in such proceedings, he is the only one who stands to be shot at. The justice of the peace, the relieving officer, the police, and the relatives all go free, but the unfortunate doctor has legal proceedings taken against him. Even when these fail, as they usually do, the anxiety and loss of time, and perhaps of practice, are immense.

It may be argued that the patient must be protected, and of course he must. The justice is supposed to be the patient's protector, and in my experience (and I certify some hundreds of cases annually in the course of my duties) he is usually an efficient protector and needs reasonable common-sense evidence placed before him before he signs an order of committal to a mental hospital. But if more safeguards are desired it would be easy to devise them. For example, additional medical certificates could be demanded; or special boards or courts for certification could be set up, of any constitution desired, with a strengthening of the lay element if thought fit; and a special panel of medical men could be drawn up to make the medical certificates of lunacy, such medical men to have had special experience in mental disease. No doubt other methods could be suggested. The point is that, proper safeguards having been provided, the medical man should be as safe as the other persons taking part from vexatious persecution afterwards. I believe the public would support a strong line on the part of the British Medical Association to have this matter put on a proper footing.—I am, etc.,

J. C. MUIR,
Medical Superintendent, Whipps Cross Hospital, London, E.11.

April 1st.

SIR,—It is to be hoped that a result of the Hume-Spry action will be to discourage one of the varieties of evidence which has figured so largely in such trials.

Any doctor who writes a certificate about the condition of a patient, whom he has not recently seen, is rebuked, with dire penalties. But he may, in a witness-box, make an authoritative statement about a case which he has not seen at all, or which he sees, for the first time, years after the alleged condition occurred. Such proceedings do nothing to help the cause of justice, they do no good to the profession, and they often cast an undeserved aspersion on the general practitioner who alone knew the facts of the case.—I am, etc.,

Wanstead, E.12, April 3rd. A. CAMPBELL STARK.

TRAUMA AS A CAUSE OF AURICULAR FIBRILLATION.

SIR,—The paper by Drs. Hay and Wallace Jones on this subject (March 26th, p. 559) is important, and the opinions expressed in it will receive due respect. As I said in my book *Incapacity or Disablement in its Medical Aspect*, "I have never met with a case in which auricular fibrillation could be attributed to sudden strain [I meant in a healthy or a diseased heart], and I should be very unwilling to believe that strain could cause it." My difficulty in the matter lies in the fact that auricular fibrillation is not uncommonly present in workers without their having any knowledge of it or any discomfort from it. I have on several occasions found it when the complaint has been nothing to do with the heart, in old workers in cotton-mills and in business men; and I hear from a medical friend, who sees many workmen in a big engineering works, that he is surprised how often he finds it in men actually working when they are examined for some reason or other not connected with the heart, and how they keep on at work with it. How, then, can we be sure that the auricular fibrillation found after some strain was not present unsuspected before it, unless the case was examined before the strain and auricular fibrillation found to be absent? The more I see of heart affections the more astonished I am

to find how some people will notice and worry over single premature systoles, and others will be quite unconscious of and continue at work with the "delirium ventriculi" of auricular fibrillation. Drs. Hay and Jones recognize a group of cases in which the date of onset cannot be determined, and, therefore, in which fibrillation was present unsuspected for some time previous to being found. My point exactly.

I can quite believe that the condition can be caused in a normal heart by severe electric shock, as in the case he refers to; violent electric stimuli can affect and disturb seriously the neuro-muscular conducting system of the auricle. In Case II I should think that the good supper, by distending the stomach, would be likely to cause or contribute to upsetting the rhythm of the heart, as this organ has such a great influence over the action and rhythm of the normal or diseased heart. It is the commonest cause of auricular premature systoles. At necropsy I have found lumps of meat in it, which have caused pain and fatal syncope when the man was hurrying along after a heavy meal and there was no lesion of the heart.

One of the best methods of dealing with heart disease, even anginal pain of any form, is to avoid exercise after meals, and especially not to hurry after breakfast; to take small substantial meals, and, again, especially a small breakfast. That the fibrillation might have been present before the strain is suggested by the fact that it has persisted for fourteen years after the trauma. How can it be proved that it was not present before the strain? Cases III, IV, and V are unconvincing, because again there is no proof that the fibrillation was not present before the strain.

I must confess, however, that I am inclined to believe that strain affecting an already diseased ventricle or a heart with some abnormality might induce auricular fibrillation secondarily, but proof is difficult. No heart that fibrillates is normal, even if the auricular fibrillation is only paroxysmal.

However, these are only my opinions: my friendly critics, who told me of their views before publishing them, hold others, and I respect them as I have no doubt courts of law will.—I am, etc.,

E. M. BROCKBANK, M.D., F.R.C.P.

Manchester, April 1st.

SIR,—The very interesting statements made by Drs. Hay and Jones (March 26th, p. 559) can hardly be allowed to pass unchallenged.

They state that in four of the five men in whom fibrillation started as the result of an accident there was no evidence that the heart was either diseased or abnormal, notwithstanding we are told that Case V had suffered from rheumatic fever "twenty years ago," and that Case IV had been in hospital for some heart affection. What evidence is there that these two cases had not suffered periodically, without realizing it, from some form of cardiac irregularity? Do not many people put down many of their precordial disturbances to indigestion, and in so doing are quite right as to the cause although ignorant as to the medium whereby they are made to realize that disturbance?

Case III suggests a very close connexion between a "good" supper of pastry and buttermilk and the heart disturbance: had this man become disabled at work it would be interesting to know to what extent personal indiscretion would be to blame for this attack. Indiscretion is a form of contributory negligence which would have to be taken into consideration should the case go to arbitration. The heart of a person predisposed to these disturbances cannot be said to be normal, nor can that person be said to be healthy. The myocardium in such cases generally shows evidence of the effects of some poisoning which is quite consistent with auto-intoxication.

Elsewhere I have drawn attention to the fact that the history of stomach troubles is more often present in cases of heart disease than even rheumatic fever. An examination of a large number of so-called "healthy men" will reveal the presence of carious teeth and puffy inflamed gums, and it will be found that their food is poor and badly cooked, whilst the ruddy glow can be traced to the cup that both cheers and blears. These are the conditions which readily conduce to auto-intoxication, and in the near future all employers will find it remunerative to have their men carefully examined on starting work as well as to take an active interest in the housing and feeding conditions of their workers, if only to discount the serious effects of applications for compensation on account of the fibrillation suggested by Drs. Hay and Jones.—I am, etc.,

Swansea, March 26th. G. ARBOUR STEPHENS.

BRITISH INSTITUTE OF PHILOSOPHICAL STUDIES.

SIR,—There is evidence that what are termed generally philosophic studies would be of advantage to many medical men, both by expanding and defining their outlook in relation to general or individual experiences and by affording assistance in the solution of practical difficulties. The need for clear thinking was never more apparent than it is to-day, when our expanded range of knowledge adds constantly to a stock of exact information, the bearings of which cannot be confined to any one branch of science, but make themselves felt in every field. "What is it all about?" is a question that every well informed man asks himself when a mental problem, perhaps with a direct reference to action, presents itself to him in a form that is not dictated by his particular equipment. And the more well informed he is, the more clear will it be to him that he needs fundamental guidance. In other words, he desires help in clear thinking.

The recently formed British Institute of Philosophical Studies exists in order to afford this help to those who need it. The general object of the Institute is stated thus: "To bring leading exponents of various branches of philosophy into direct contact with the general public with the purpose of satisfying a need, felt by many men and women in every walk of life, for greater clearness and comprehensiveness of vision in human affairs."

Medical men and women are to-day meeting many difficulties that are arising through the vast development of their science—developments of knowledge, of technique, and of administration; these are being accompanied by a broadening of view in their ranks, and also by a multiplication of the relations of medicine to society brought about by far-reaching changes in the law. The position must therefore often arise when medical men or women need clearness and comprehensiveness of vision. They would benefit by an opportunity of taking counsel with those in other sections of activity, who may be meeting their own problems from a different angle or who may be able to give an opinion on medical problems which gains in breadth and public influence through its detachment from medicine.

Further, medicine by co-operation can confer on those other sections of activity the advantages of sharing considered medical opinion and of learning the arguments relied upon for its establishment.

Sociological and psychological questions arise constantly out of all medical practice, and not only out of those sides of medical practice apparently concerned with mental disease or moral conduct, while metaphysics must play a part in any comprehensive attempt to distinguish between normal and abnormal conditions, physical or mental—indeed, between health and disease. A general philosophical equipment will be of great use to the practitioner as a supplement to all detailed scientific knowledge, for it will conduce to clear thinking.

For these reasons we advocate the claims on members of the profession of the British Institute of Philosophical Studies, the temporary offices of which are at 88, Kingsway. The honorary secretary would be glad to give any information desired. The subscription payable by members of the Institute is only £1 1s. per annum.—We are, etc.,

MIGRAINE.

SIR,—The discussions at the last Annual Meeting of the Association[1] and at a meeting of the Section of Medicine of the Royal Society of Medicine,[2] and the letters that have appeared in the JOURNAL during the last few months, have shown two wholly different conceptions as to the nature and treatment of migraine. The letters have been from medical men, mostly sufferers themselves, who have given us the benefit of observation and experiment on their own persons.

These all maintain that faulty metabolism and hepatic deficiency are the important causes of migraine, and have satisfied themselves that for its prevention and control abstention from certain articles of diet and attention to the action of the liver and bowels are the important points. Dr. P. J. Cammidge[3] adduces evidence from the laboratory that during attacks of migraine the urine frequently contains acetone bodies, and that hypoglycaemia may be present. Attacks of migraine may be benefited by glucose, because its administration "enables the defective liver cells to carry out their functions more efficiently." On the other hand, Professor E. Bramwell in his opening paper, and subsequent speakers at the Annual Meeting, attached but the slightest importance to food poisoning or derangement of liver as a cause of migraine. In his recent paper at the Royal Society of Medicine Dr. C. P. Symonds only mentions cursorily that "other toxins derived from faulty metabolism of fats, sugars, or proteins may be responsible," while he lays greater stress on other points. Of a dozen speakers who followed only two remarked on the importance of diet as the cause.

For many years I have been convinced that attacks of migraine point to some metabolic defect, whereby food poisons are allowed to enter the circulation. When these have accumulated to a certain extent an attack is determined. The periodicity of migraine has been emphasized by several of your correspondents, and is difficult to explain by any ocular condition, or by changes in the pituitary gland, or by other suggestions made at the meetings. Not only this, but some sufferers find that the headache is on one side in one attack and on the other side for certain in the next. Further, an attack definitely and constantly follows the taking of particular foods and drinks which experience has shown to be harmful.

Experiment is usually required in each case to ascertain what are the causative articles. One man's food is another man's poison, but in general my practice has been to follow Alexander Haig, and begin by cutting off all meat, meat soups and extracts, eggs, tea, coffee, and all alcohol, and to restrict sugar, chocolate, and animal fats. In a large proportion of patients this reduction produces an obviously good effect, and it is only necessary to modify the diet subsequently according to observations. In a small proportion fish and fowl, many fruits, and all sweets and jams may have to be excluded. The patient may be restricted to breads, biscuits, cereals, milk, milk cheeses, and certain vegetables and nuts, etc. Few persons will persist with such limitation, but they will have discovered what are their particular enemies, and they will know that the control of symptoms is in their own hands.

Though diet is the most important cause, other factors have, of course, to be taken into consideration. I assume that there is an exalted sensibility of some part of the brain. This may be what is hereditary, and probably explains the pathognomonic constancy with which women have their attack of migraine before or during the menstrual period, when their nervous systems are disturbed. Excitement, worry, and overwork are mentioned by several writers, and generally allowed to be powerful factors. The effect of eye-strain perhaps may be explained by this abnormal excitability of the brain. Migraine is sure to follow in many persons a train or motor journey or a visit to a cinema from the fatigue of the eyes caused by watching rapidly moving objects, and in some cases from the vibration. The correction of errors of refraction certainly helps many sufferers, but I think that the majority had already discovered for themselves that overuse of the eyes was their trouble. A large proportion of the population have some amount of astigmatism and do not suffer from migraine, while others find that errors of diet are more important than slight errors of refraction. Dr. G. Maxted kindly sends me the following information. Of 1,000 consecutive private patients, thirty complained of migraine. Of these seven had no error of refraction, while the remainder had astigmatism—mostly slight. Ten had myopic astigmatism, the others hypermetropic. Though all the twenty-three persons were asked to report on themselves, only four did so. Of them, three had found relief from the use of glasses, and the fourth stated that she was not relieved.

Most of the drugs found useful in migraine are nerve sedatives, such as luminal, bromides, and the phenacetin class. Others, such as sodium salicylate, are thought to help elimination of poison. For the attack itself Fairre cachets have seemed to me to be especially efficacious, but aspirin is the most useful drug in some cases.

Apart from causes acting directly through the nervous system, cold, bad air, and excessive exercise may be mentioned. Some patients find that they are worse in a too bracing or stimulating climate. Cold checks the action of the liver, and a hot bath is helpful to some sufferers. Exercise probably stirs up toxins which had been stored away. It is generally agreed that the amount of meat consumed by these patients must be particularly attended to, but I think that low living is as common as high living amongst them, and that they are drawn from all classes of society. I find them characterized by low rather than by high blood pressure, and of spare rather than of plethoric build. But the two opposite types of constitution are seen in sufferers from migraine.

These rough observations leave several points wholly unexplained. Why is the headache one-sided? Why do the same things produce an attack in one person and relieve it in another, or do each at different times? Tea, coffee, champagne, and calomel are examples of this double action.

Amongst my cases I have looked up those of three doctors who consulted me for migraine some years ago, and have asked them for their final conclusions. The first tells me that after he had been subject for years to an attack every week, he went six months without one while he abstained from all red meat. Latterly he has relaxed, and has had some return of slight attacks. He knows that whisky will bring on his migraine, as noted by "Consulting Surgeon" in his letter to the JOURNAL, and that he has no ocular cause. The second doctor writes: "Without any question I am the better for giving up all meat; even a fried egg or some vegetables fried in lard will produce genuine migraine." Raw apples have the same tendency. After mentioning such recognized causes as nerve strain and bodily fatigue, he goes on to refer to overuse of his eyes, and states that this does not bring on genuine migraine unless he has also transgressed dietetically. The third doctor is satisfied that his migraine is chiefly attributable to taking certain articles of diet. He names apple first, and says that a mouthful will bring on an attack in a few hours. Chocolate, cocoa, eggs, and meat, except in very small quantity, are found to act as poisons. If he is tending towards an attack a glass of champagne will precipitate it, but if he is throwing an attack off more champagne will help him. Beer is poison to him, as to many such patients, and to a less extent sherry and other wines. He is better from the use of spectacles, but he lays less stress on them than on diet. He says that aphthous stomatitis is often associated with attacks of migraine.

The articles of diet mentioned by my patients correspond closely with those found to be provocative of migraine by your correspondents. I also find mention in my notes of their more anomalous symptoms of migraine—exaggerated sense of smell and of hearing, difficulty in speech and confusion, pain in one or other arm, and weakness of the right arm.—I am, etc.,

THE SURGERY OF GASTRIC AND DUODENAL ULCERS.

SIR,—I have read with considerable interest Mr. Flint's comments on Mr. Souttar's figures of gastric and duodenal ulcers, for I have on many occasions pointed out that my own figures differed from those usually published.

Up to the time of my last analysis, some three or four months ago, the figures for the cases of chronic ulcer upon whom I have personally operated privately and at the London Hospital are as follows:

Uncomplicated lesser curve ulcers	278
Uncomplicated duodenal ulcers...	278

It is curious that the numbers in these groups should be identical, but as to their nature there can be no question. The lesser curve ulcers are never nearer than 1½ inches to the pylorus, and are often very remote. In addition to these groups it is my custom to distinguish pyloric ulcers as a separate variety—a custom with which all surgeons will not agree. My reason for so doing is that any ulcer which involves the stomach, even in a small part, has a tendency—although it may be a very slight one—to become carcinomatous, while duodenal ulcers have not this tendency. Hence, any ulcer which even in part passes over the pyloric white line, or over the pyloric vein, is grouped as "pyloric" and not as "duodenal." In this group there were 162 cases. Even if these were grouped as duodenal it would only cause the proportion of duodenal and gastric to be about 3 to 2, which varies considerably from Mr. Flint's proportion. Moreover, these are only the *uncomplicated* cases, and there are not included hour-glass stomachs, ulcers found on the lesser curve after gastro-enterostomy performed elsewhere, perforated ulcers, etc. The figures for the completed groups are:

Duodenal ulcers	278	
Perforated duodenal ulcers	23	
Gastro-jejunal ulcers	33	
		334
Lesser curve ulcers...	278	
Hour-glass stomach	49	
Perforated gastric ulcers...	36	
After operation elsewhere, etc....	72	
		435
Pyloric ulcers	162	

So that if the pyloric are not included there is a considerably greater frequency of gastric over duodenal. Even if the 162 pyloric are added to the duodenal group the figures very nearly approximate. The difference between my figures and those of Mr. Flint can hardly be accounted for by a place distribution, for my cases have come from all parts of the globe, and even those operated on at the London Hospital have been sent from widely distributed areas. It is probable that they are simply the accidental differences found in dealing with relatively small groups of cases, for my own—of just under 1,000 cases—is much too small for vital statistics. That this is probably so is shown by the sex differences. In my own series all ulcers have been more common in men. Of the total of 931, 716 were males and 215 females. All observers agree that duodenal ulcers are more common in men, but in my series this was also true of the lesser curve ulcers, although many—especially the Continental surgeons—have had a different experience. In my uncomplicated group of this variety there were 211 males and 67 females. Even if the 49 cases of hour-glass stomach—a condition only found in the female—are included, these figures are 211 and 116, thus still giving a marked preponderance in the male. —I am, etc.,

A. J. WALTON.

London, W.1, April 1st.

ALBUMINURIA IN INFLUENZA.

SIR,—Having occasion to examine for physical fitness a large number of prospective employees annually, I have often found a varying trace of albumin in the urine of men who have recently had influenza. I have always regarded this as of toxic nature. In a recent case, whose certification I have postponed for review in three months, quite a heavy trace was noted. On referring to an old edition of Osler I found that nephritis is mentioned as one of the rarer complications of influenza.—I am, etc.,

FRANK B. SKERRETT, M.B.Lond.

London, E.15, April 2nd.

"BIRTH CONTROL."

SIR,—In the course of Dr. Dunlop's letter (March 26th, p. 597) he states that at the present day only a very small proportion of couples can get really sufficient food for themselves and more than three children. This, unfortunately, is all too near to the truth. But when he ascribes it to slow increase of the world's food supply he is assuredly straying from the facts. Now every mouth born into the world is born with a pair of hands, and the resources of Nature are inexhaustible and indestructible. Though it is undoubtedly all too true that willing hands, here and there up and down the globe, often cannot get ready enough access to Nature's resources, none the less foodstuffs are without question produced to-day in greater quantities proportionately to the population living than ever before.

In one of the latest publications from the League of Nations (the "Memorandum on Production and Trade," Geneva, 1926) it is shown that between 1913 and 1925 the population of the world increased by 5 per cent., but the production of foodstuffs (meat excepted) increased by 13 per cent., and the total production of raw materials by 17 per cent.

The productiveness of decent agricultural land has been increased at least seven to eight times in the last 150 years by the advances in scientific knowledge and in the intensive use of land. Lord Bledisloe at a British Association meeting last autumn pointed out that the wheat area had trebled in the United States of America during a period in which the population had trebled, but that the production of wheat had more than trebled.

The causes of poverty, involving insufficiency of food for the many, lie in other directions than a deficiency of the world's production of foods. It can be admitted, however, that not only are foodstuffs, like other commodities, badly distributed, but also produced in much less quantities than they would be if fuller advantage were taken through wider education, etc., of the potentialities of to-day. In this connexion two factors of importance to your readers come in, because both have to do with matters of public health and sanitation, and they are: (1) Over-urbanization. Wider support should be given to the garden city movement, which includes the plan of the appropriation by the community of community-created ground rents. And (2) the waste of nitrogenous manures which goes on year by year in most civilized lands through our present methods of the disposal of human corpses and human excreta. We cast £20,000,000 worth of nitrogenous manure into the sea each year around our own shores. If the earth is robbed of her natural food, which should automatically increase with every increase of population, she will not respond automatically to provide an increased food supply, and can only behave in niggardly fashion in spite of increase of knowledge and more scientific agriculture.—I am, etc.,

S. VERE PEARSON.

The Sanatorium, Mundesley, March 27th.

THE MORTALITY OF ACUTE APPENDICITIS.

SIR,—I endorse the article by Mr. Hunter on mortality from appendicitis (March 19th, p. 508).

One point is rarely mentioned in discussions on the question—a point which further weights the argument in favour of operation. To anyone trained to think analytically and statistically it must be clear that to the mortality from appendicitis treated by delay must be added the deaths from other surgical conditions which were more urgently in need of operation—for example, delayed operation which still has to be done for internal strangulation of bowel, perforated duodenal ulcers, and intestinal obstruction.

Surely deaths from these conditions should figure under deaths from "treating appendicitis by delay." They really

figure under deaths from the true cause found at operation too late. Similarly, to be fair, a death (much rarer) from pneumonia which simulates appendicitis so that a mistaken operation is performed, should figure as a death from an operation "for" appendicitis.

It is poor consolation to a patient treated medically for a few days, who then has to be operated upon for internal strangulation, and dies, to be able to reflect: "Ah, but I didn't have appendicitis! I had, statistically speaking, an internal strangulation."—I am, etc.,

Liverpool, March 24th. FRANK JEANS.

RESISTANCE TO QUININE IN MALARIA.

SIR,—The point raised by "I.M.S." in your correspondence columns of March 19th (p. 542) has already been discussed by others. Perhaps my own experience may be of interest. I first contracted malarial fever in the Shan States in 1897. I found powders, pills, and tablets of quinine sulphate useless, and the acid solution made me vomit; I was able to retain the powder dissolved in brandy, and soon got rid of the fever. Later on, when I was staff surgeon in Mandalay, I had a similar experience with many officers and their wives. This experience was repeated in the Punjab and again in the Northern Transvaal. It was not until I served in Macedonia during the war that the superiority of quinine hydrochloride was brought to my notice. I found it was not necessary to give intramuscular injections of quinine if the hydrochloride could be obtained, and was administered by the mouth. During the last five years I have treated a good many relapses of malarial fever in England. The records showed that the patients had previously been on the intensive course of quinine sulphate (the method usually prescribed). Under the hydrochloride every patient soon recovered, their blood films being all negative. I have heard from some of them since who have been free from fever for four or five years, and so I consider these cured.

In my opinion there can be no doubt that "I.M.S." is correct in suggesting that the so-called resistance to quinine is merely lack of absorption, as the sulphate has always been the chief preparation used everywhere on account of its cheapness.

The comparative value of the two salts is shown in the following table (after Manson).

Sulphate of Quinine.	*Hydrochloride of Quinine.*
Percentage of the alkaloid in the salt ... 73.5	Percentage of the alkaloid in the salt ... 81.8
Solubility in water ... 1 in 800	Solubility in water ... 1 in 40

Hale-White's *Materia Medica* gives the solubility as follows:

Sulphate:	*Hydrochloride:*
1 in 800 of water.	1 in 35 cold water.
1 in 65 of alcohol (90%).	1 in 3 of alcohol (90%).

I always give these preparations of quinine dissolved in alcohol in bad cases.—I am, etc.,

R.A.M.C., DIPLOMA IN TROPICAL MEDICINE.

March 28th.

THE OPERATION OF TONSILLECTOMY.

SIR,—Presumably laryngologists will agree that in tonsillectomy an ambidextrous technique is desirable. But I think that neither of your correspondents (Mr. Lodge, BRITISH MEDICAL JOURNAL, January 8th, p. 56, and Mr. Roe, March 26th, p. 564) goes far enough, since they confine their remarks to the guillotine method. In enucleating tonsils by dissection, ambidexterity is at least quite as useful. For if the same hand be used for both tonsils, either the operator must change his position for one less comfortable, or else either his hands or instruments must be awkwardly crossed in or near the patient's mouth.

Personally I aim at being as ambidextrous as possible in every kind of surgical manœuvre. And in tonsillectomy, whether by guillotine or dissection, I have for years been so completely comfortable with either hand that at any moment it is a matter of indifference to me which one I am using.—I am, etc.,

H. LAWSON WHALE, M.D., F.R.C.S.

London, W.1, March 28th.

SIR,—I was so impressed with the similarity of the method of tonsillectomy described by Mr. A. J. S. Roe in his memorandum appearing in your issue of March 26th (p. 564), with my description of this same operation entitled "Tonsillectomy by propulsion and avulsion," which appeared in the *Practitioner* for August, 1925, that I would like to flatter myself with the belief that Mr. Roe had read that article; in any case I am glad to know that there are at least some others besides myself who appreciate the supreme advantages of ambidexterity and team work in carrying out the safe and rapid enucleation of the tonsils with the blunt guillotine in *all* cases. Personally I think the adenoids should on no account be removed until the tonsillectomy having been carried through on both sides, the patient is lying in the lateral (Sims) position, in which the air passages form an inclined plane, with the mouth in the most dependent position, the advantages of which are obvious.—I am, etc.,

J. B. HORGAN, M.B., Ch.B., D.L.O.,
Honorary Laryngologist to the North Charitable Infirmary, Cork.

March 29th.

THE VALUE OF ULTRA-VIOLET RADIATION IN SURGICAL TUBERCULOSIS.

SIR,—Dr. J. Hunter is reported, on page 567 of the BRITISH MEDICAL JOURNAL (March 26th, 1927), as having said, at a meeting of the Forfarshire Medical Association, held in Dundee on February 16th, that when ultra-violet radiation was used in Dundee "in tubercle of bones, joints, and spine the effects were not good."

Professor Reyn of the Finsen Institute, who has had the greatest experience of actinotherapy, has frequently stated that the results obtained by the application of carbon arc light baths in the treatment of surgical tuberculosis are brilliant; and the published results of the Finsen Institute confirm this statement. Seventy-seven per cent. of the cases of "closed" surgical tuberculosis were cured and 83 per cent. of the cases with sinuses or abscesses.

The cause of these contradictory results is, I think, found in another remark of Dr. Hunter's—that "erythema and pigmentation should not be produced." As Professor Reyn has said, "A poor equipment will give poor results, and so will even the best equipment if the technique be faulty."—I am, etc.,

Newcastle-on-Tyne, March 26th. W. KERR RUSSELL, M.D.

THE MODERN TREATMENT OF HERNIA.

SIR,—Mr. Geoffrey Keynes (March 26th, p. 595) does less than justice to his powers of exposition. His meaning was abundantly clear; I only took leave to doubt, on the strength of the experimental work quoted, whether the union of flap and ligament would be strong enough to prevent the formation of a hernia which would otherwise develop; and I think the question still remains open.

The remarkable case of femoral hernia that he records is most interesting, and illustrates well the elasticity of Gallie's method in meeting all kinds of difficulties in the treatment of hernia. Its bearing on the question of clearing the sac (from above or below) is not so obvious. I should have guessed that it would be easier to free such a sac from above than to deal with the usual type with a narrow neck by the inguinal route. But the case is hardly relevant to the discussion of the routine method of dealing with the sac in ordinary cases. Mr. Keynes distinctly implies in his paper that it should be done from below; I venture to question that, and I think most surgeons who are familiar with the Lotheisen method will agree with me.—I am, etc.,

Brighton, March 29th. M. FITZMAURICE-KELLY.

BILHARZIA OVA AND THE TEST TUBE.

SIR,—In your issue of March 5th (p. 418) Dr. Christopherson stated that I have assailed the statement "that antimony tartrate kills the ova deposited in the tissues during treatment for bilharzia disease."

This statement is incorrect. My article referred to by

him (which was a criticism of Christopherson's previous work) dealt only with the action of tartar emetic *in vitro*, and not with its action on ova inside the body. The experiments described in that paper in 1921 and the conclusions arrived at have been confirmed by other workers. The action of tartar emetic on bilharzia ova in water or saline solution in a test tube has no relation whatever with its action inside the body. The results observed are adequately explained by the physical phenomenon of osmosis. This is not a unique example, for emetine *in vitro* has not the specific action it has on the *Entamœba histolytica*.—I am, etc.,

M. KHALIL, M.D.; Ph.D., M.R.C.P.Lond.,
March 19th. Professor of Parasitology, Faculty of Medicine, Cairo.

Obituary.

DAVID MacEWAN, M.D., LL.D.,

Emeritus Professor of Surgery, University College, Dundee.

DR. DAVID MACEWAN, Emeritus Professor of Surgery in University College, Dundee, died at his residence in that city on March 31st. Professor MacEwan, who was in his eighty-first year, had been in failing health for a considerable time. He was born in Kinross-shire, and was educated at Perth Academy. He received his medical education in the University of Edinburgh, and graduated M.B., C.M. in 1867, and proceeded M.D. in 1880. After graduation he acted as house-surgeon at the Royal Infirmary of Dundee. In 1870 he commenced practice on his own account in that town, and for some time lectured on operative surgery. In 1898 he was appointed professor of surgery in St. Andrews University, a post which he held for twenty-two years, retiring in 1920, when he was succeeded by Professor L. Turton Price. He had already retired, in 1910, from the post of surgeon to Dundee Royal Infirmary, and on that occasion received a handsome testimonial and was entertained at a public dinner. Though he held the position of consulting surgeon to the Infirmary, he resumed active service during the war, operating with all his old skill. After his retirement from the chair the honorary degree of LL.D. was conferred upon him in 1921 by St. Andrews University. He was president of the Dundee Branch of the British Medical Association shortly after its formation, and he delivered the address in surgery at the Annual Meeting in Carlisle in 1896. Respected for his intellectual gifts, Dr. MacEwan was loved for his qualities of heart; his wide sympathy and quiet service endeared him, not only to his patients and students, but also to his colleagues.

He was the author of several contributions to current medical literature, including "A series of abdominal cases," "Treatment of surgical tuberculosis," and "Bier's treatment by venous congestion." He was held in great respect by all classes of the public in Dundee, where he enjoyed a large practice. He had been twice married, and is survived by a widow and by a son of his first marriage.

C. H. WATTS PARKINSON, M.R.C.S., L.S.A.,

Formerly member of the Council of the British Medical Association.

WE regret to record the death of Dr. Charles Henry Watts Parkinson on March 29th, at Wimborne, aged 80. He was the son of the late Dr. Charles Parkinson, who had practised in Wimborne before him. He received his medical education at Guy's Hospital, and obtained the diplomas M.R.C.S.Eng. and L.S.A. in 1869. He afterwards commenced practice in Wimborne, where he was appointed medical officer of health, having obtained the D.P.H.Ed. in 1889. He retired from practice about 1900.

Dr. Watts Parkinson had been an active member of the British Medical Association, and from 1899 to 1902 was joint honorary secretary, with the late Dr. Vawdrey Lush of Weymouth, of the Dorset and West Hants Branch, of which he was president in 1891 and a member of the Branch Council from 1909 to 1913. He was honorary secretary of the Bournemouth Division from 1904 to 1905, vice-chairman in 1907, and chairman in 1908. From 1899 to 1900, and again from 1907-8, he was a member of the Central Council of the Association, and attended its meetings regularly; he had served previously on the Parliamentary Bills Committee.

Dr. Parkinson was for many years coroner for East Dorset; this appointment he held at the time of his death, being then one of the oldest coroners in England. He formerly held a commission in the Volunteers, and was awarded the V.D. Besides these Dr. Parkinson had many other activities: he was a justice of the peace, a member of the Wimborne Board of Guardians since 1903, and the senior member of the governing body of Wimborne Minster. He was also a prominent and much respected Freemason, having taken the deepest interest in the craft for the past fifty-six years. At the time of his death he was Provincial Grand Mark Master of Dorset.

DR. HORACE EYRE HAYNES, who died on March 12th, was born at Evesham in May, 1846, the son of Dr. J. B. Haynes. From Epsom College he went to St. Bartholomew's Hospital. He took the diplomas of M.R.C.S. and L.S.A in 1869, and afterwards joined his father and eldest brother in a very extensive practice. He left Evesham in 1900, and subsequently paid special attention to the treatment of mental cases at a home he established at Brentwood. In 1917 he retired to Brighton, but in 1923 returned to Evesham, where he died. Dr. Haynes took a prominent part in the public affairs of his native town, and was elected mayor of Evesham in 1884 and again in 1885. He showed a keen and practical interest in the old Volunteer movement, was granted a commission in the Worcestershire Volunteers in 1872, received the Volunteer Decoration, and retired after many years' service with the rank of lieutenant-colonel. He was a good rifle shot and won the Licensed Victuallers' Cup in 1875 and the Beauchamp Cup in 1887 and in 1889. He was vice-president of Epsom College and an ex-president of the Worcester Medical Society.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons has this week discussed the Landlord and Tenants Bill, the Architects Registration Bill, and other measures, and has also debated problems of unemployment and of British policy in China.

The text of the Trades Disputes and Trade Unions Bill, introduced by the Government, has been issued, and the second reading is to be taken after Easter. The bill, among other objects, proposes to except from the protection of the Trades Disputes Act, 1906, a general strike or sympathetic strike calculated to coerce the Government or intimidate the whole or a substantial part of the community.

On April 5th the Unionist Health and Housing Committee, with Dr. Fremantle presiding, heard from Mr. Sutcliffe and Mr. Barber, representing the Joint Council of Qualified Opticians, a statement of the case for the Optical Practitioners Bill. *The Government has appointed a select committee to investigate the same matter.*

Bill for the Registration of Nursing Homes.

In the House of Commons, on April 1st, Mrs. Philipson moved the second reading of the Nursing Homes (Registration) Bill. Its principle, she said, had already been approved by a Select Committee, and, as the Committee had recommended, the bill proposed that the local supervising authority should be the county council or the county borough council. Persons carrying on nursing homes were required to apply for registration. In homes already in existence registration would not be refused if the person in charge was unqualified, but the person superintending the actual nursing must be a qualified nurse. The bill proposed to repeal Part II of the Midwives and Maternity Homes Act, 1926, thereby bringing maternity homes within the purview of this general measure. Although inspection was to be by officers of the local authority, the bill contained a proviso designed to prevent inquiry into the medical records of individual patients. Other clauses defined "nursing home" and redefined "qualified nurse." Mr. G. Hurst, in seconding, said that as the law stood at present the words "nursing home" had no legal significance. The abuses in some nursing homes had not been realized by the public before the publication of the report of the Select Commitee, but the Select Committee desired that the inspecting officer should be, as in the case of maternity homes, the local medical officer of health, assisted by a qualified nurse to deal with all questions of nursing and a sanitary officer to deal with sanitation. Evidence before the Select Committee had satisfied all its members, including the medical members, that abuses were rife in homes

run by doctors as well as in homes run by unprofessional persons. No doctor of any standing would object to having his home registered. Registration conferred a status, not a stigma.

Mr. A. V. Alexander asked if "nursing home" included "convalescent home."

Mr. Hurst said that if in a convalescent home nursing was given that home would come within the definition.

Sir Douglas Newton moved the rejection of the bill, which would bring undue centralization. Non-county boroughs should not be shut out from its administration. Mr. Harrison seconded. Dr. Drummond Shiels said that until he served on that Select Committee he had not known that a bill of this kind was so much required. What most impressed the Committee was the number of cases of chronic senile poor people who were kept under deplorable conditions. It would be far better that these unfortunate people should be cared for by a public authority. He would seek to have Scotland included in the benefits of the bill. Sir Richard Luce, who had also been a member of the Select Committee, said he had come to the question with an open mind. The evidence given had caused him rapidly to change his views, and he now recommended the bill. When the original bill was projected some two years ago there had been considerable objection from the medical profession, which had not realized the seriousness of the question. The point the profession made of the sanctity of professional secrecy between patient and doctor had been fairly met in the present bill. With the evidence obtained by the Select Committee before them doctors no longer demanded the inclusion of a clause exempting from inspection those homes under the charge of medical practitioners. The bill would bring about a necessity for reasonable co-ordination between maternity and general nursing homes under registration. It would guarantee a reasonable standard of nursing. Proprietors of nursing homes and doctors had given evidence that the supervising authority should be an entirely independent body. The Committee felt that the authority should be wide, with a whole-time officer to do the inspection. He pointed out a drafting defect by which a clause in the bill appeared not to allow patients in maternity cases in nursing homes to be attended by a doctor. He drew attention to the provision that the supervising authority might pass by-laws requiring notification of any death in a nursing home with statement of its cause. He declared that it was not part of the duty of a nursing home to give the cause of death.

Dr. Elliot, speaking for the Government, said it was reasonable that the bill should be read a second time and become law. Differences existed between England and Scotland, and should be recognized by separate legislation. The principle of registration and inspection was accepted on all sides of the House; the question of the powers of non-county boroughs could be further considered in Committee; the recommendation of the Select Committee need not be taken as prejudging the issue. Sir Cyril Cobb, who had been chairman of the Select Committee, said that most cases had to be sent to a nursing home in a sudden emergency by relatives, who had to take the nursing home practically on chance. Dr. Vernon Davies said that the bill would remove a great scandal. Until the Select Committee sat the medical profession as a whole had no idea that inspection and registration of all nursing homes would be required, but after reading the evidence it had no objection to legislation for the inspection of medical men's own homes. Amendments might be moved in Committee to further safeguard the interests of nurses.

The motion for rejection was not pressed, and the bill was read a second time without a division.

Lead Poisoning.

During the discussion of the Civil Estimates, in the House of Commons on March 31st, Mr. Rhys Davies renewed the discussion on the British Government's decision not to ratify the Geneva Convention prohibiting the use of white lead in paint. He referred to the resignation of Sir Thomas Legge from the post of Chief Medical Inspector of Factories at the Home Office in protest against this decision, and congratulated Sir Thomas Legge on his courage. Mr. Rhys reminded the House that fifty operative painters died each year in this country from lead poisoning through the use of white lead in paint, and 200 were always suffering from lead poisoning. He protested that the Government had, through the India Office, invited the Bombay Government to "torpedo" the White Lead Convention in India. Replying for the Government, Captain D. King said Sir Thomas Legge had reached the pensionable age nearly four years before resigning. There was no obligation on the British or on any other Government to ratify the draft Convention. Since the Government had issued regulations governing the use of white lead paints, these regulations had been accepted by the appropriate trade joint council with very small alterations which would be adopted by the Home Office. Mr. Wallhead said that as a practical man he did not think the regulations could be made effective.

Refacing the Houses of Parliament: Sandstone and Silicosis.

On a vote for expenditure on the buildings of the Houses of Parliament, which was carried by the House of Commons on March 31st, Captain King explained that £20,000 was asked for the repair of the stonework. On expert advice the repairs were to be executed in Stancliffe stone. Mr. Gardner objected. He said this stone came from Darley Dale. The Office of Works paid an extra sum per hour to men working in that kind of material because of the danger involved. Sir Thomas Legge had written that the quarrying and dressing of sandstone in Derbyshire, Yorkshire, and round Edinburgh had cost a multitude of lives. In Derbyshire the death rate from phthisis was high in the sandstone areas, low in the limestone. Mr. Gardner said that according to an inquiry by the medical officer of the Derbyshire County Council, the death rate per 1,000 in the years 1901 to 1910 in the areas from which this stone came was 13.7 from phthisis among 124 gritstone workers. Among 426 stone workers, some in gritstone, some in limestone, in the two Matlocks and the two Darleys the death rate was 7 per 1,000. Among persons employed in and about limestone quarries and works it was 1.71 per 1,000, among limestone workers 1.52, and among persons employed in and about coal mines in the same district 0.68 per 1,000. The standard phthisis death rate was 0.77 per 1,000, and the death rate among Portland stone masons was 1.4 per 1,000. Dr. Brown, a medical officer of the Home Office, had reported that silicosis advanced by slow stages, and the men affected appeared to be unchanged, but ultimately they died very quickly of it. Mr. Gardner declared that the pneumatic tool expedited the disease. Portland stone was now being used for building even in sandstone areas. Lord Hartington thought Mr. Gardner had slightly exaggerated the risk to the workers in gritstone. Captain King said that to reface the Houses with Portland stone would cost over £3,500,000. Sandstone quarry owners in Derby had decided in 1922 to have all their operatives examined by the medical officers of health. Of 291 operatives, 5 were found to be suffering from silicosis and 7 from lung diseases; 84 of the men were between 40 and 49 years of age; 51 between 50 and 59; 21 were 60 years or over. The medical officer of health for the North Darley Urban District also supplied figures showing that in 1919 the death rate from phthisis was 0.34, and the only death from phthisis was that of a woman. Captain King admitted that silicosis existed among workers in sandstone. The Office of Works and Home Office had carefully considered that point and intended to take every possible precaution to secure the health of those who worked on this stone by damping the stone and in other ways. The workshops to be erected within the precincts of the Palace of Westminster would have roofs which could be opened completely in fine weather. Dr. Vernon Davies said Mr. Gardner was confusing the work of the mason with that of the quarryman. There was no danger to any mason who used stone of this description, either in preparing it for building or in building.

Colonel Lane-Fox, replying to Dr. Vernon Davies, on April 5th, said that silicosis was not, in general, a disease which it was required to report. Detailed information could not therefore be given as to the number of cases among stone workers for the last three years for which statistics were available, or as to the number of deaths, or the number of cases which developed pulmonary tuberculosis and died therefrom. The kinds of stone most liable to produce silicosis were the more siliceous sandstones and granite. More information would be available on this point when the results of a medical inquiry into the dust danger among workers in sandstone, which had been instituted by the Home Secretary, were known. The Mines Department was collaborating in this inquiry. Before deciding whether silicosis should be scheduled as an industrial disease the Government must have the report.

Another Mental Deficiency Bill.—The Mental Deficiency (No. 2) Bill, presented by Mr. Rhys Davies, [illegible] the Labour party proposals for amendment of the [illegible] 1913. It proposes to redefine idiots, [illegible] persons, and moral defectives, inserting in [illegible] "from birth or from an early age, or in consequence of physical injury or sunstroke or encephalitis lethargica." In the case of persons under 14, "that they by reason of such defectiveness appear to be incapable of receiving proper benefit from the instruction in ordinary schools" is added as a reason for classification as feeble-minded, in addition to "that they require care and supervision for their own protection or for the protection of others." Additional safeguards are proposed on the placing and retention of defectives in homes or institutions. A clause, which is said to be in accordance with the recommendations of the Royal Commission on Lunacy, proposes to dissolve the Board of Control for the purposes of the enactments relating to lunacy as well as for the purposes of those relating to mental deficiency, and to set up a new board. This is to consist of a chairman appointed by the Home Secretary, one legal commissioner, one medical commissioner of either sex, appointed by the Home Secretary, and one female commissioner. The Home Secretary is to have power to appoint two medical commissioners instead of one. Of fifteen assistant commissioners five are to be medical. (It may be found that a clause proposing to alter the Lunacy Acts is out of order in a bill whose title restricts it to mental deficiency.) The bill proposes that where mechanical means of bodily restraint are applied to a defective in an institution or certified house a certificate signed by a qualified medical practitioner, describing the means used and why, shall be forwarded to the Board, any restraint otherwise applied to be a misdemeanour. Many minor amendments are proposed in the principal Act.

Young Offenders.—The report of the Departmental Committee on the Treatment of Young Offenders has been issued. The Committee recommends that immediate steps should be taken to deal with the serious lack of accommodation for mental defectives; that the Mental Deficiency Act, 1913, should be amended to remove the difficulty caused by the words "from birth or from an early age" (a bill proposing this is now awaiting report in the House of Commons), and that persons suffering from the after-effects of encephalitis lethargica should not be dealt with as criminals, but placed in suitable institutions as subjects for medical care. The bill also recommends that the juvenile court should have jurisdiction to deal with all offences, except homicide, committed by persons under 17. No child under 8 should be charged with any offence. Much better facilities, it is considered, are required for the examination and observation of young offenders under 21, in order to estimate personal factors, especially mental and

physical health. The Committee remarks that the increase in encephalitis lethargica has emphasized the need for careful examination. "All the resources of approved medical science in relation to the functions of the mind should be available under any system of observation." The Committee states that in existing places of detention for persons under 16 little is done in the way of special medical examination. In many cases the juvenile courts have no regular way of ensuring medical examinations. At least three observation centres or central remand homes should be provided by the State. There should be a medical examination in all cases in which it is proposed to inflict whipping, but the courts should be able to order a whipping for any serious offence committed by a boy under 17. (Three members of the Committee dissent from this last recommendation.) Imprisonment should be abolished for young persons between 16 and 17, except where a certificate of unruliness or depravity is given. The distinction between reformatory and industrial schools should be abolished. Sentence of death should not be passed on any person under the age of 18. Recommendations are made for after-care and for dealing with cases of neglect.

Vaccination.—On April 4th Mr. Groves asked the Minister of Health whether he was aware that the medical officer of health for Southport received a letter from the Ministry of Health stating that the severity of the vaccination reaction reported from Southport had been noticed in other districts, and appeared to be caused more by the technique used in vaccinating than by the virulence of the vaccine lymph, and suggesting that a single incision four-fifths of a centimetre long should be made and no criss-cross incision. Sir K. Wood replied that the Minister was aware that a letter was written by a medical officer of the Ministry (after having made a local inspection) to the medical officer of health for Southport, generally on the lines set out in the question, except that it was made clear that four marks should be made, each by a single line incision, not four-fifths of a centimetre, but 4 to 5 millimetres long. The official view of the department was set out in the instructions to vaccinators under contract, and the suggestions made in the letter were consistent with that view.

Notes in Brief.

On April 4th Earl Winterton informed Mr. Lansbury that the Indian Lepers Act provided that compulsory segregation of pauper lepers might be enforced in areas to which the Act was made applicable by the local provincial government. He understood that there were dispensaries in many places for the treatment of early cases of the disease.

Mr. Chamberlain, on April 4th, stated that he was considering whether a public inquiry should be held into the report of the special committee by the board of guardians on the Swaffield Road Institution, Wandsworth, as to the alleged maladministration of the infirmary wards.

In the twelve months ended February last about 2,000 war pensioners with below-knee amputations had been fitted with metal limbs. At one of the largest limb-fitting centres more complaints were received from pensioners wearing the metal limb than from those wearing the wooden type.

The Minister of Health has given provisional figures showing that 27 men and 61 women over 100 years of age died in England and Wales between 1922 and 1926.

During the twelve months ended last February 22 men and 4 women died from natural causes when under detention in prisons in England and Wales.

Veterinary staffs in countries under the Colonial Office were increased in 1926 as follows: Nigeria 2, Sierra Leone 1, Kenya 2, Tanganyika 2, Bechuanaland 3, Straits Settlements and Federated Malay States 2, Fiji 1.

Within the area of the Surrey Local Education Authority in 1926 were 259 ascertained educable mentally defective children. Of these, 41 were at special schools, 133 at public elementary schools, and 3 at other institutions.

The last revision of the medical scales for merchant ships was issued in 1924.

Medico-Legal.

LUNACY CERTIFICATION.

De Freville v. *Dill.*

IN the King's Bench Division on March 29th, before Mr. Justice Avery and a special jury, the hearing was begun of an action in which Mrs. May de Freville, the wife of Mr. G. P. H. de Freville, claimed damages for alleged negligence in certifying her to be insane on June 9th, 1926, from Dr. A. V. Dill, a medical practitioner, of Stroud.

The defendant pleaded the protection of Section 330 of the Lunacy Act, 1890, as he signed the certificate in good faith and acted with reasonable care; his conclusions regarding the plaintiff's condition at the time he certified her were correct.

The Plaintiff's Case.

Mr. Cremlyn, in opening the plaintiff's case, said she married in 1917, and lived with her husband in London for nearly twelve months, and in 1918 a son was born. The marriage became very unhappy because her husband did not like children. In 1922 the company of which her husband was manager failed, and the only home he could offer her was Oakridge Vicarage, near Stroud, the residence of his father, the Rev. F. de Freville, who had vehemently objected to the marriage. On May 29th, 1926, the plaintiff visited her own father at Wokingham, appearing then as normal as she had always been. On June 7th she saw her brother in London; on June 9th she discussed her affairs with a Stroud solicitor. On May 11th she saw the defendant, Dr. Dill, for the first time. She had just "told her husband what she thought of him," and his mother rang up Dr. Dill, who, without any introduction, entered the bedroom where she was packing, preparatory to leaving the house. Dr. Dill then suggested to her that she was very excited, but she denied this and said she was leaving because of her husband. On May 15th her husband called on Dr. Dill and consulted him about her "periodic attacks of excitement," but Dr. Dill then said she was not certifiable and suggested she should become a voluntary boarder in a mental institution. On June 9th, after seeing the solicitor, she returned to the vicarage and went into the library, where she saw her husband, her father-in-law, and her son. The boy ran to her, but the vicar snatched him away and the child was removed from the room. Then the vicar said to his son: "Put her out," and the plaintiff became very angry, and, possibly, excited. Her husband seized her and threw her out of the front door; she tried to get back through a French window, but a sister-in-law slammed the window in her face, breaking the glass. She then got into the servants' hall, but the vicar locked the door leading to the kitchen. Eventually she heard the vicar telephoning to Dr. Dill to come immediately because she was "in a great state of excitement." Dr. Dill saw her alone in the servants' hall; she told him that all she wanted was to see her son and that she would then leave the house. Dr. Dill and her husband's family then had a consultation, which she interrupted, and there was a scene. Dr. Dill telephoned to the relieving officer, who came to the vicarage, and a little later a policeman took her to the Gloucester County Asylum. On the way they visited the house of a magistrate, who signed a summary reception order. Counsel urged that none of what took place on that night was strictly authorized by any section of the Lunacy Act, 1890. The following morning the plaintiff was seen by two other doctors, who stated that she was not of unsound mind. Dr. Dill's certificate said that Mrs. de Freville was very excited, talked wildly, threatened to kill her husband, refused food, would not sit down, insisted on seeing her son, although the child cried and obviously did not want to see her, and was in a state of acute mania.

The plaintiff, in evidence, said she might have been excited, but the other statements were untrue. Her child was not in the room when the doctor was at the house. The certificate also stated that she had ordered goods without reason or authority, and had had the bills sent to her mother-in-law. In ordering these goods, witness said she was acting on her solicitor's advice to order such clothes as she thought necessary and to send the bills to her husband.

Cross-examined by Mr. Singleton, K.C., the witness agreed that she had begun an action against her father-in-law alleging false imprisonment, though she admitted that he had been very kind. About eighteen months before June, 1926, she summoned her husband for desertion. A letter from her husband to her father, dated June 4th, 1926, in which he referred to her as "one who is so good at heart when she is herself," was only partly sincere. She denied the suggestion that before Dr. Dill came she rushed at her father-in-law shouting that she would kill him, or that she struck the vicar in the eye with her clenched fist. She did not attack her husband and tear his coat. She agreed that they were always unhappy at the vicarage.

Asked why Dr. Dill, who had only seen her once before, should certify her unless he believed her to be of unsound mind, she replied that it was because her husband wanted to get rid of her. This was a conspiracy between her husband, his father, his invalid mother, and the doctor—his mother mostly.

Mrs. de Freville denied that she threatened to protest in her father-in-law's church if he tried to preach. She agreed that for four years the vicar provided the means for her and her husband and her child to live. She denied saying, on June 9th, 1926, if she had a revolver she would "shoot them all," or that if she had a knife she would "cut all their throats." She never told her sister-in-law that she had most terrible nightmares, or that she thought of committing suicide. She never threatened to throw her son under a tramcar; such a suggestion was false and horrible. She never assaulted the vicar, although she admitted having been bound over on that charge.

Evidence on behalf of the plaintiff was given by Mr. R. E. Stuart, solicitor, of Stroud; Miss Warner, matron of the Gloucester County Mental Hospital; Miss Hunter, nurse at the hospital; Dr. John Marnan, medical superintendent of the County Asylum, Gloucester; Dr. Thomas C. Smith, senior medical officer at the Second County Mental Hospital, Barnwood, Gloucester; Mrs. Sleep, the plaintiff's sister; Mr. P. A. G. Bishop, the relieving officer at Stroud; Dr. T. B. Hyslop, and Dr. J. Risien Russell.

Both Dr. Marnan and Dr. Smith, in evidence, said when they examined the plaintiff on June 10th she was quiet and mentally normal. If she had been in a state of acute mania at 10.30 on the previous night they would hardly have expected her to be in the condition in which they found her the following morning.

Mr. Bishop, in his evidence, said he was called to the vicarage by Dr. Dill on June 9th. Dr. Dill filled up and signed the medical certificate on the statutory form, and the witness filled up the statement of particulars, obtaining some from the husband and some from Dr. Dill. When he was about half-way through the filling up of the form the plaintiff came in very excited, talking and throwing her arms about. She came over to the witness with her arms in the air and asked who he was and what he was doing there, and ordered him out of the house. She said she had come down for her child whom the family had refused to allow her to see. She kept on talking and shouting in the library, and Dr. Dill and the witness went into the hall to complete the form. Mrs. de Freville refused to come with him, and therefore a policeman and the witness took her by the

arms and Dr. Dill saw them into the car. They called at the house of Mr. Aldridge, a magistrate, and he signed a reception order. The magistrate did not have a chance to talk to the plaintiff as she was talking all the time. Cross-examined, the witness said that when he saw Mrs. de Freville he formed the opinion that she was temporarily of unsound mind. She became quieter on the journey.

Dr. Hyslop said he saw the plaintiff on March 2nd and March 7th, 1927, and she gave a rational, coherent, and calm explanation of the circumstances giving rise to the allegations. He did not think that the certificate was a proper one to make. "I should have adopted the same course as the person at Gloucester Mental Hospital and said she was unjustly detained and not a proper person to be kept under care and treatment." In reply to Mr. Singleton, who asked if a doctor found a patient raving, if in his presence she assaulted one or more persons and threatened to kill one or more persons, was it not his duty to send for the police and the relieving officer? the witness said "No; he should send for nursing aid and treat the patient on the premises if possible to prevent her being sent to an asylum, and ascertain whether the condition is evanescent. It is a doctor's duty not to be precipitate in these cases."

Dr. Risien Russell, in his evidence, said that facts communicated by others should not be used without confronting the patient with the persons making the statements. The statement as to refusing food was untrue, and it was therefore a false certificate. Cross-examined, Dr. Russell said that he knew of no state of insanity lasting only a few hours.

Case for the Defence Opened.

Mr. Singleton, in opening the case for Dr. Dill, said no one would be more pleased than the defendant and his advisers if they could believe that the plaintiff was now and would remain sane. The jury had not to try whether the plaintiff was sane now, nor even whether she was sane on June 9th, 1926.

Dr. Dill, in his evidence, said both the vicar and his wife had been his patients. He first saw the plaintiff on May 11th, 1926, when he was called to the vicarage. She told him things were quite impossible at the vicarage, and she was packing to leave. She refused treatment, and said that she was sorry he had been sent for. He had been told that the plaintiff had had a row with her husband. The husband came to see the witness, and told him that she had attacks about once a month, and seemed to be getting worse. The husband said that she had thrown a knife at him, and had threatened to throw her child under a tramcar. On June 9th he went to the vicarage in response to an urgent telephone call. The plaintiff was in the servants' hall, walking up and down in a very excited state, with a blood-stained handkerchief tied round her wrist. She talked excitedly, and did not wait to answer his questions. She wanted to see her son and to go into the village to get a bed. She said she did not know when she had had food last. She then had a cup of tea, and he got her to take a tablet on the understanding that she should see her son. When the vicar came in she said: "There you are, you holy man," and added that if he tried to preach next Sunday she would certainly get up and protest. The vicar then showed the witness his eye, which had a small bruise on the eyeball. The witness did not think it desirable that the plaintiff should see her son or take him away. In the witness's presence the plaintiff struck Miss de Freville in the face with her closed fist, and he heard her exclaim to her husband, "My God! I could kill you." Witness decided that it was undesirable that the plaintiff should remain at the vicarage, both for her own sake and also for the sake of the other people who were in the house, for he did not know to what extent she would go on injuring, or attempting to injure, others, including her own child.

Cross-examined, Dr. Dill said he never asked Mrs. de Freville whether her husband's statements about her were true. He had no opportunity; she could not answer even simple questions. Asked why it was necessary to send Mrs. de Freville into an asylum to get her away from the environment of the vicarage, he said he saw no other alternative. He watched the plaintiff thoroughly for five hours, and her actions were entirely consistent with unsoundness of mind.

Counsel: Can you refer me to any textbook which says, as you have, that acute mania is liable to clear up very rapidly?—I am not conversant with the textbooks. It is eleven years since I qualified.

You have told us that you are a general practitioner with little experience in mental cases, and you say that it was not necessary to take a second opinion?—It was sufficiently obvious to me what she was suffering from.

Was she suffering from acute mania?—As I meant it.

Was she suffering from acute mania as that term is known to the medical profession?—Possibly not.

The Jury Discharged.

At this stage of the case the jury informed the judge that they had arrived at a conclusion adverse to Dr. Dill, and asked whether they could stop the case.

Mr. Justice Avory said the jury had come to a premature determination adverse to Dr. Dill without hearing the end of his evidence, and also most material evidence that was to have been tendered on his behalf. Unless Dr. Dill was prepared to submit to judgement, the proper course was to discharge the jury from giving a verdict.

Mr. Singleton said Dr. Dill could not consent to judgement, as the evidence of the witnesses who would have been called from the vicarage was as important as, if not more important than, Dr. Dill's evidence.

Mr. Justice Avory: I shall take the responsibility of discharging the jury without giving a verdict.

The jury were, accordingly, discharged.

Universities and Colleges.

UNIVERSITY OF LONDON.

Delay in Registration after Passing Qualifying Examination.

ON January 29th (p. 213) we published a letter from "Senior" stating that a young practitioner whose name appeared on the pass list of the London M.B., B.S. on December 8th, having forwarded a fee for registration to the General Medical Council on the following day, found later on that he could not be registered until January 26th—that is, seven weeks after the publication of the list and after complying with what was required. Having on January 16th given a death certificate he was informed by the General Medical Council that his degrees could not be registered because the University of London had not sent the necessary information to the General Medical Council. We communicated with the Registrar of the General Medical Council, who informed us that representations had already been made to the University authorities, but he was good enough to take the matter up again and to enlist the interest of the representative of the University of London on the Council; by his efforts a new ordinance has been passed as follows:

> That the Vice-Chancellor be empowered to attach on behalf of the Senate the seal of the University to the pass list of the M.B., B.S. Examination for Internal and External Students after the lapse of a fortnight from the date of the examiners' meeting in cases where the pass list cannot be approved by the Senate within that period; and that this be deemed to be a case of urgency within the meaning of Standing Order No. 134

Consequently it may be hoped that the hardship to which attention has been called will not arise in future.

UNIVERSITY OF DURHAM.

THE following candidates have been approved at the examination indicated:

THIRD M.B., B.S.—*Pathology and Bacteriology; Materia Medica, Pharmacology and Pharmacy; Public Health; Medical Jurisprudence*: M. J. Arnott, T. L. Kelly, H. D. Ord. *Pathology and Bacteriology; Materia Medica, Pharmacology, General Principles of Therapeutics, and Pharmacy; Public Health; Medical Jurisprudence*: *C. Goldstein, *J. M. Tait, *H. G. Ungley, H. M. Brown, D. S. Buchanan, W. C. E. Diamond.

* With second-class honours.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examinations indicated:

DIPLOMA IN TROPICAL MEDICINE.—C
J. D. Bilimoria, W. M. Burns, E
M. Farid, *A. M. [illegible] E. [illegible]
N. M. Hodivala, L. [illegible] Y. S Maclay,
Johnson, J. S. K[illegible] L. Malhotia,
H. G. Maguire, [illegible] H. M. Nevin,
B. S. Manghirmalani, J. N. Mehra, A. J. Murray, [illegible]
N. T. Olusoga, D. B Parakh, M. R Peters, *R. S. Rao, S. R. A. Shah,
J. F. Southward, Frances C. Thompson, B. J. van de S. de Villiers,
R. Walkinshaw.

DIPLOMA IN TROPICAL HYGIENE.—T. A. Austin, B. Barrowman, W. W. Besson, J. C. St G Earl, J. Hamilton, C F. McCoa, Winifred H. Mitchell, R. Nixon, W. S. Ormiston, A. Robertson.

* Recommended for the Milne medal.

UNIVERSITY OF MANCHESTER.

T. N. FISHER, M.B., Ch.B., has been approved at the examination for the certificate in school hygiene.

The following awards have been made: Dauntesey Medical Junior Scholarships: (1) C. H. T. Wade, (2) R. V. Wright and Florence Nightingale divided. Sidney Renshaw Prize in Physiology: M. C. G. Israels and W. W. Kay divided.

UNIVERSITY OF DUBLIN.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., PART I.—[illegible] P.
prudence and Hy [illegible] rd,
[illegible] on,
[illegible] P.
I [illegible] J. A. Dowds, I. le Roux.
Meiring, J. E. Wells.

PART II.—*Medicine*: *R. A. Q O'Meara, M. Gerber, W. F. Lane, M. F. N. Griffin, R. W. T. H. Stewart, R. S. F. Hennessey, G. S. Smith, R. D. Whitecare, C. F. Cope, P. Brangan, S. D. K. Roberts, G. O. Taylor, E. A. Ellis, C. L. Day, N. J. U. Mather, M. Sherowitz, S. B. Dairymple, S. R. Elmes, M. G. J. Booysen, Norah W. Brown, W. F. Knobel, C. de W. Meintjes, A. C. C. Charles, D. M'M Casson, H. C. Weir. *Surgery*: S. Behr, G. O. Taylor, G. S Smyth, S. Gurevich, P. M. Garry, G. D. Edwards, M. G. J. Booysen, M. Gamsle, [illegible] *Midwifery*: *P. M. Garry, *E. M. Gamsle, [illegible] R. M. Moore, J. R. Hanna, H. Dundon, [illegible] thaus, I. le Roux.

D.P.H., PART I.—*Chemistry; Bacteriology and Parasitology; Physics, Meteorology, and Climatology*: M. Halligan, Brenda M. Young, Sarah M. Coghlan, J. V. M'Nally, Kathleen M. Ball, Kathleen M. Kennedy, Margaret E. Pedlow.

PART II.—*Sanitation (including Sanitary Construction); Public Health Administration; Hygiene and Epidemiology; Sanitary Law and Vital Statistics*: Anna M. Allen.

DIPLOMA IN GYNAECOLOGY AND OBSTETRICS.—Anne Sivet, P. Mehta.

* Passed on high marks.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

AT the monthly business meeting, held on April 1st, the President admitted the following candidates, who had been successful at the spring final examination under the conjoint scheme for Ireland, to the licenses in Medicine and Midwifery of the Royal College of Physicians of Ireland:

W. Burgess, E. P. Carroll, Bridget Crawford, A. Fung, A. F. E. Harbord, C. P. Hearty, J. Kenny, W. G. Myers, A. P. McEvilly-Jordan, J. F. McGeough, P. O'Callaghan, Philomena T. M. Pierse, T. Simpson, H. T. G. Westropp, D. P. Rudstein.

THE following candidates, possessi[illegible] approved for the M.D. degree at the [illegible] the winter-session just ended: S. S. Bhatnagar, H. N. Warner Collins, Gladys H. Marchant.

Medical News.

A POST-GRADUATE course for general practitioners will be conducted by the staff at the James Mackenzie Institute for Clinical Research, St. Andrews, from June 14th to 28th. It will bear on the recognition and treatment of the early stages of disease. Lantern demonstrations will be given by the honorary director and members of the clinical staff, anatomical demonstrations by Dr. Kirkpatrick, physiological lectures and demonstrations by Professor Herring, and chemical demonstrations by Dr. Hynd; Dr. Matthew Fyfe will deal with clinical pathology and Mr. Smith with radiology. Clinical lectures will be given at the Dundee Royal Infirmary, when Professor Patrick and Professor Price will deal with surgical and medical subjects respectively. The fee for the course is £5 5s. Further information can be obtained from the Secretary of the institute.

THE Fellowship of Medicine announces that owing to the Easter vacation the special courses in April will not start until the end of the month. A three-weeks' course in medicine, surgery, and gynaecology at the Royal Waterloo Hospital for Children and Women commences on April 25th. On April 26th will be given the first [illegible] demonstrations on tropical diseases, on [illegible] 2 p.m., at the London School [illegible] Medicine. Four lecture demonstrations on electro-therapy will be given by Dr. C. B. Heald at the Royal Free Hospital on Wednesdays at 5.15 p.m., beginning on April 27th. Copies of all syllabuses, the general course programme, and the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

AT a meeting of the Medical Society of London, held on March 28th, the following were elected honorary Fellows: Professor Irving Cameron (Canada), Professor Sir Charles Sherrington (Oxford), Professor H. C. Jacobaeus (Stockholm), Professor K. F. Wenckebach (Vienna).

SIR CHARLES SHERRINGTON, G.B.E., O.M., M.D., F.R.S., Sir Henry Head, M.D., F.R.S., Sir George Newman, K.C.B., M.D., and Professor C. J. Martin, M.D., F.R.S., have recently been elected Fellows of the New York Academy of Medicine.

THE Savill (Memorial) Oration of the West End Hospital for Nervous Diseases will be delivered in the house of the Royal Society of Medicine by Dr. Gordon Holmes on Thursday, April 21st, at 5 p.m. The subject is local epilepsy, and the chair will be taken by Dr. Percy Smith. Members of the profession and medical students are invited to attend. The Savill prize (offered biennially, value £15) will be awarded at the end of this year; full particulars can be obtained from the secretary at the hospital (Welbeck Street, W.1.)

THE annual meeting of the Royal Medical Benevolent Fund will be held at 11, Chandos Street, Cavendish Square, W.1, to-day (*Friday, April 8th*), at 5 p.m.

SIR JAMES BERRY, President of the Royal Society of Medicine, has been elected a member of the Athenaeum Club under the provisions of Rule II of the club, which empowers the annual election of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service.

THE house and library of the Royal Society of Medicine will be closed from Thursday, April 14th, to Tuesday, April 19th, both days inclusive.

THE Robert Jones medal and prize offered by the British Orthopaedic Association for 1926 has not been awarded.

AT St. Thomas's Hospital at noon, on April 26th, the St. Thomas's House (a residential club for students) will be opened and a war memorial unveiled by the Archbishop of Canterbury.

HELP was given to nearly 500 mothers and children by the National League for Health, Maternity and Child Welfare during 1926, and the annual report contains details of many emergencies overcome. Although the annual expenditure is approximately £5,000, the annual subscriptions are under £600, the balance being obtained from the activities of the society, which are largely self-supporting. Holidays and convalescent treatment were provided for many mothers and children and several health lectures were delivered, the physical training cinematograph film prepared by the league proving very popular. Over 429,000 copies of publications by the league were distributed, with considerable benefit to its finance.

A NEW edition has been issued of the *Handbook of the American Medical Association of Vienna*. This contains information about various facilities for medical post-graduate work in this city, and will be found very useful by all proposing to study there. It may be obtained free of charge from Dr. A. I. Haskell, VIII, Alserstrasse 9, Vienna, Austria.

THE second international course in gynaecology and cardiology at Franzensbad will be held from May 22nd to 26th, 1927.

DURING the celebration in 1930 of the French occupation of Algiers an international congress on malaria will be held, when the discovery of the parasite of malaria by Laveran at Algiers in 1880 will be commemorated.

THREE congresses at Vienna this year will deal respectively with psychiatry, microbiology, and neurology. At the first, from April 21st to 23rd, the programme will include the psychology of schizophrenia and the care of psychopathic patients. The secretary is Dr. G. J. Ilberg, Sonnenstein, Pirna, Saxony. At the second conference, from June 7th to 9th, the subjects will be experimental cancer and protective inoculation; further information may be obtained from Professor R. Kraus, Zimmermanngasse 3, Vienna IX. The third conference, from September 15th to 17th, will include a discussion on the anatomy, physiology, and pathology of the sensory nervous system. Inquiries should be addressed to Dr. K. Mendel, Augsburgstrasse 43, Berlin.

THE centenary of the birth of Vulpian will be celebrated in Paris at the same time as that of the death of Pinel, on the occasion of the annual meeting of the Société de Biologie and the eighth international neurological congress (May 27th to June 2nd). Further information can be obtained from Dr. H. Colin, 22, Rue Gay-Lussac, Paris V^e^.

PROFESSOR JULES BORDET, director of the Institut Pasteur at Brussels, has been nominated a corresponding member of the Royal Academy of Spain.

THE population of Italy has increased from 25 million in 1862 to 42 million in 1926 in spite of the losses caused by earthquakes, influenza, war, and the fall of the birth rate. The average duration of life has risen to 53, and the mortality, which was 30 per 10,000 in 1880, has fallen to 16 per 10,000.

ACCORDING to recent statistics, the number of insane persons in different parts of Italy is 59,393, or 1.5 per cent. of the population.

THE medical faculty of Freiburg University has conferred the distinction of doctor *honoris causa* on Tatsukichi Irisawa, professor of internal medicine at Tokyo and one of Naunyn's former pupils.

THE following changes have recently occurred in the German medical faculties: Professor G. von Bergmann has succeeded Professor Kraus in the chair of internal medicine at Berlin; Dr. Franz Volhard, professor of internal medicine at Halle, has succeeded Professor von Bergmann in the corresponding chair at Frankfort; Professor Hans Wintersten has succeeded Professor Karl Hürthle in the chair of physiology at Rostock; and Professor Otto Pankow has succeeded Professor Opitz in the chair of obstetrics and gynaecology at Düsseldorf.

PROFESSOR EMILE DE GRÓSZ has been appointed president of the committee on post-graduate study in Hungary, Professor Cornelius de Scholtz vice-president, and Dr. Béla Johan secretary. During 1926 ten post-graduate courses were arranged in Budapest, Szeged, and Debreczen, and eight numbers of a periodical devoted to medical education were published.

AN anonymous donor has put the sum of 100,000 francs at the disposal of the Société de Neurologie of Paris to be awarded to the discoverer in the course of the next two years of a certain cure for disseminated sclerosis. Candidates must be members of the Société de Neurologie or at least of French nationality.

THE late Dr. T. Claye Shaw, who died at Cheltenham in January last, left estate valued at £53,854.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

DR. JEANIE MACRAE (Mallaig, Inverness-shire) asks for suggestions for the treatment of a patient who is suffering from hyperpiesia (blood pressure 170–180), accompanied by excessive secretion of frothy saliva. The nose is blocked, and this necessitates continual spitting, particularly during a continued conversation.

MORBID SHYNESS IN A CHILD

"E. C. M." writes: I would suggest to "K. H. G." to invite other children into the house—one, two, or more—say, twice daily, and talk and play with them naturally, disregarding completely the child's existence during these times. No attempt should be made to include her and not the slightest notice taken of her shy habits. I believe that gradually the child will venture to join in on her own account. The mother's anxiety is reflected in the child's inability to do what is expected of her.

DR. B. E. COOK (Doncaster) writes in reply to "K. H. G.": May I recommend him to read Cameron on *The Nervous Child?* I would suggest that if the child's mother were to see a medico-psychologist (such as the one whose address is reported in the JOURNAL for March 26th on page 582) she would probably receive the necessary help in what is, after all, a problem for the home rather than the surgery.

"HONG-KONG DOG."

"M.D." asks for information about the disease colloquially called "Hong-Kong dog."

*** "Hong-Kong dog" is the local name given to a diarrhoeic condition which attacks most newcomers to Hong-Kong shortly after their arrival. It was formerly attributed to alcoholic indulgence, but this is definitely not the case. It is most common in the earlier months of the year, and may recur year after year, and in some, fortunately few, instances, after a succession of such attacks, the condition does not clear up, but seems to pass imperceptibly into true sprue.

LETTERS, NOTES, ETC.

THE UREA CONCENTRATION TEST IN NEPHRITIS.

DR. J. BARKER SMITH (London, S.E.) writes: The authors of the article in the BRITISH MEDICAL JOURNAL of January 8th (p. 51) have given a valuable and simple test for ascertaining renal function. But I am somewhat puzzled that the mere percentage of urea should mean so much. The technique mentioned there is to me somewhat obscure. My difficulty in understanding and suspicion, however, arise in the most simple, and therefore most valuable, statement under section *(a)* at the end of the article: "An analysis of the urea content of a series of specimens of ordinary urine. If these show an adequate urea percentage, then obviously a urea concentration test is not necessary." It seems to me that "adequate urea percentage" is left to the personal experience of the reader for interpretation. In the absence of estimating the day's output of urea we are compelled to consider "adequate" the amount of urea relatively to the specific gravity of the sample passed. I find in the examination of some hundreds of samples of urine, excluding those which are albuminous or saccharine, that the output of urea approximates, or is *en rapport* with, the specific gravity of the urine. So for other ordinary constituents of urine. If we make a ratio of the urea per thousand by multiplying by a hundred and dividing by the two last figures of the specific gravity the quotients or ratios would approximate for samples from sp. gr. 1010 to 1030—say a ratio about 70. I should be very sorry for this valuable article to be passed over because of any obscurity and not put into practice.

DR. ARCHIBALD CAMERON.

"H. G." writes: There are degrees in everything, even in treason, and had Dr. Cameron been content, as most of his fellow rebels were, to accept the verdict of "Drumossie," he might have returned in due course to his native land and ended his days in peace. But, as "Nomadic Doctor" properly states, he went about his "royal master's business," and it is important to know what that business was. It was neither more nor less than the kidnapping of the Royal Family, for that is what the Elibank conspiracy aimed at. The Government had full knowledge of this, but thought best not to make it public—probably from the desire to avoid shedding more blood. Hence the ignorance prevailing up to recent times of the true reason for the execution of Dr. Cameron.

WIRELESS MEDICAL CONSULTATIONS AT SEA.

DR. W. H. BROAD (Liverpool) writes in reply to Dr. D. D. F. Macintyre's invitation for suggestions (JOURNAL, March 12th, p. 493) to be embodied in the new edition of the *Ship Captain's Medical Guide:* As a preliminary measure might I suggest that the items in Scale III be numbered? The general consideration of the whole subject is one which will require much discussion and cannot for a moment be so summarily treated as suggested by Dr. F. F. Bond in his letter of March 14th (BRITISH MEDICAL JOURNAL, March 19th, p. 542).

LONGEVITY IN A FAMILY.

A MEMBER of the South Australian Branch of the British Medical Association (Adelaide) refers to recent notes on unusual family longevity (JOURNAL, 1926, vol. ii, pp. 236 and 365), and states that his wife's grandparents, who were pioneers of South Australia, had eleven children; two out of three who died were then 81 and 64, while eight are living, their present ages being 86, 83, 82, 80, 76, 74, 71, and 67. Six of these, who reside in South Australia, regularly visit an aunt, who is just reaching her 100th birthday. This aunt landed in South Australia on December 28th, 1836, the day it was proclaimed a British province. She is a great reader and corresponds with many friends, taking a keen interest in all that is going on. She was the youngest of a family of nine. Two brothers met with accidental deaths; one sister died at the age of 90 and two at 82, while three brothers died at the ages of 97, 90, and 65.

FOREIGN BODY IN RECTUM.

DR. M. HONIGSBERGER (Birmingham) writes: The following case is so unusual that it may possibly be of interest to record it: I was consulted by a man of 65 years, a miner, who complained that he had been awakened at 3 a.m. by profuse diarrhoea without pain or vomiting, but when he got out of bed he could hardly walk because of a severe pain in his rectum, neither could he sit down. Having known of a similar case where the cause was a fish bone in the rectum, I expected to find this the cause, and on rectal examination I found something resembling a fish bone, but it was bent at such an angle and non-flexible and so impacted in the rectal wall that I had great difficulty in extracting it. Instead of a fish bone, however, the foreign body proved to be a bent twig of a tree 2¼ in. long and almost 1/4 in. diameter. The twig was unbendable. The patient was unable to explain how it got there. He is not a mental case, nor a drunkard, and it seems almost inconceivable that a twig of such a size and so unflexible could be swallowed and the swallower not be aware that something abnormal had been gulped down; moreover, the twig must have been propelled throughout the entire length of the alimentary tract (except the last part) in its longitudinal axis, for the patient has had no abdominal pain lately.

THE CHEWING OF GUM.

DR. W. J. BURNS SELKIRK (Birmingham) writes: Falling into thought, I surmised that there must be some reason for the chewing of gum, even though it be not formulated. Experimenting, I find it has a decided sedative action; hence, perhaps, its abounding utility in the land of hustle. Presumably, it is analagous in effect to the baby's comforter. It seems capable of producing even the state of mind of the ruminating cow and its Buddhistic calm. With it one may endure a prolonged surgery attendance with good-humoured tolerance, and the evil chances of the putting green cease to irritate and become curiously amusing, to the extent almost of inducing a dual personality. I would not be surprised if it could relieve even the hard-pressed surgeon of the necessity for expletives. It may be offered as a substitute to the excessive cigarette smoker, and for the chocolate habit; for frayed nerves and insomnia as a sedative. The material has a considerable sale even in this country. Why?

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 46, 47, 48, 49, 52, and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 126.

An Address
ON
HEART DISEASE AND PREGNANCY.

DELIVERED TO THE NEWCASTLE-ON-TYNE DIVISION OF THE BRITISH MEDICAL ASSOCIATION

BY

SIR THOMAS OLIVER, M.D., F.R.C.P.,

CONSULTING PHYSICIAN TO THE PRINCESS MARY MATERNITY HOSPITAL, NEWCASTLE-ON-TYNE.

IT is now several years since I first became interested in the subject of heart disease and pregnancy. In the early part of my professional career pregnant women were not supposed to be admitted into the wards of the Newcastle Infirmary, so that my experience was mostly gained in outside consulting practice. Recently greater facilities have been afforded me of studying the problems in a practical manner in the Princess Mary Maternity Hospital with its eighty beds. My desire is to create among the younger members of the profession interest in one of the complications of pregnancy worthy of their attention and well deserving of study. Death in maternity, from whatever cause, is a tragedy of womanhood. The high death rate of women during and shortly after the puerperium is a cause of public uneasiness and calls for abatement, but I do not intend to discuss the subject of septic infection.

Although in the main a physiological state, pregnancy is beset with many possibilities which tend to endanger the life of mother and child. Severe haemorrhage, for example, may occur before or after parturition, from which the patient may apparently recover; yet in many of these women, on auscultating the cardiac area, there will be heard, years afterwards, a soft mitral systolic murmur which was not present before the excessive loss of blood. In other words, as the result of the haemorrhage the heart has remained enlarged, and, being badly nourished, has never quite regained its normal size—a circumstance which will materially affect the course of succeeding pregnancies and increase the risk of the puerperium.

The Condition of the Heart in Pregnancy and the Effect of Pregnancy upon the Heart.

As far back as 1825 Larcher, who was then an interne in the Paris Maternity Hospital, drew attention to the relationship of the two, basing his opinions upon the examination of the heart of 130 patients who had died in the hospital, most of them of puerperal sepsis. It may be taken for granted that in most of the patients the heart had been healthy except so far as it might have been influenced by the puerperal fever. It was his opinion that the human heart becomes normally enlarged during utero-gestation, that it is mainly the left ventricle which is affected, the right heart showing few if any alterations, also that during lactation the heart tends to return to its normal size unless subsequent pregnancies follow each other in rapid succession.

It is possible, as Angus Macdonald,[1] writing in 1878, maintained, that Larcher exaggerated the cardiac condition. On the other hand, it is generally admitted that pregnancy influences the quantity and quality of the blood in the body, and that there is thrown upon the vascular system increased work in order to meet the requirements of the mother and the foetus *in utero*. Larcher's views did not meet with general acceptance even by his own countrymen. One of his strongest opponents, however, was a German, Herman Lohlein, who stated that the average weight of the heart in pregnant women is not greater than that of their non-pregnant sisters. On the whole the consensus of medical opinion is that in pregnancy there is a slight increase in the size and weight of the heart, and my own experience confirms this. The average weight of the female heart between the ages of 20 and 25 years is, according to Peacock, 8¼ oz., while in the case of pregnant females it is over 9 oz. In addition to the increased weight of the heart, the blood pressure must be considered. This becomes raised, and is frequently associated, as pregnancy advances, with conditions that are dangerous. The systole of the ventricle becomes stronger and its contents are discharged under higher pressure. This physiological condition is necessitated by the maternal and foetal requirements. Obstetricians recognize that in abnormal circumstances a rising blood pressure may be the forewarning of eclampsia. At any rate, where the blood pressure rises above 150 mm. of mercury the patient should be watched, carefully dieted, and the emunctory organs maintained in good order. The blood pressure rises and wanes with the pains during the first and second stages of labour, and declines in a normal case three or four days after the confinement.

It is after the supervention of pregnancy that many women, hitherto unaware of having experienced any inconvenience in walking or taking gentle exercise, become conscious of a sense of breathlessness on exertion, and since in pregnancy there is usually a tendency for the body weight to increase, for the volume of blood to become greater, and the size of the uterus larger, this raises the question whether there is an increased cardiac output. It is this problem which Stander, Duncan, and Sisson[2] set themselves the task of investigating. The new physiology, with its carefully-thought-out methods of research and instrumental equipment, has given a fresh impetus to the study of medical problems and has compelled us to approach these in a manner impossible to be done four decades ago. The experimental method was made use of by the research workers just mentioned, dogs, non-pregnant and pregnant, being employed. Six female dogs were carefully trained so that they were completely under control, and were unlikely therefore by movement or otherwise to vitiate the results aimed at. Two of the dogs became pregnant. The results of the experiments are interesting, for the investigators found that of the four non-pregnant animals kept under observation for more than a year the heart output varied very little, also that the "minute volume" had a more constant value than the "systolic output." One circumstance particularly worthy of mention is that during oestrus the cardiac output was increased and therefore resembled in a miniature manner what takes place in pregnancy. These observers found that during gestation the cardiac output kept gradually increasing all through, until shortly before delivery the output had increased 53 per cent., and that after delivery it slowly returned to what might be regarded as the normal. The conclusion was that the cardiac output is increased by one-third to one-half during the later months of pregnancy, and since during the whole period of utero-gestation there is never a fall of the arterial blood pressure, the heart is really called upon to perform a greater amount of work. This raises the question whether this is accomplished by the heart becoming hypertrophied or simply by the organ calling upon its latent reserve. Opinions differ, as I have incidentally stated, in regard to the occurrence of hypertrophy of the left ventricle of the heart, but there is not the least doubt "that some mechanism must be called into play to meet the increased demands of pregnancy." Given a healthy heart and a normal pregnancy, the heart is capable of rising to the occasion, but it is another thing for a woman who has a cardiac valvular lesion and whose myocardial fibres are not typically sound; how will her heart bear the additional strain which pregnancy is likely to impose upon it?

Some Statistics.

Taking the records of the Princess Mary Maternity Hospital for the last three years, I find that 9 pregnant women with heart disease were admitted in 1924; 3 were cases of mitral stenosis, 3 of mitral incompetence, and 1 of aortic regurgitation, while 2 suffered from myocardial weakness. All the patients successfully passed through the process of parturition, and were able to return to their homes. During 1925 the cardiac patients admitted numbered 16; 2 were suffering from mitral stenosis, 6 from mitral incompetence, 3 from aortic regurgitation, and 5 from cardio-valvular defects, not stated, and myocardial feebleness. Three deaths occurred: one woman, the subject of aortic regurgitation, developed anginal pains, and died a few hours after her admission, undelivered; one woman was admitted in a moribund condition with mitral regurgitation, six and a half months pregnant—she died nine and

a half hours after admission, undelivered; another woman, the subject of mitral regurgitation, died a few hours after admission. There were 13 cardiac patients admitted during 1926; 8 suffered from mitral stenosis, 3 from mitral incompetence, and 2 from aortic regurgitation. One patient, a 3-para, aged 37, the subject of mitral stenosis, died ten days after her confinement from pulmonary embolism. Of the 38 patients 13 suffered from mitral stenosis, 12 from mitral regurgitation, and 6 from aortic regurgitation. Four patients (10.6 per cent.) died in the hospital. It is more than likely that in some of the patients tabulated as mitral regurgitation, stenosis was present as well.

As a contrast I will take the number of similar cases admitted into a general hospital—the Western Infirmary of Glasgow. Dr. R. A. Currie of that city has been good enough to send to me, with Professor T. Monro's permission, the number of patients admitted into Professor Monro's wards during the last ten years. The total number for that period is 27. Of these, 7 were cases of mitral stenosis, 7 of mitral regurgitation, 3 of aortic valvular disease, and 6 of auricular fibrillation. Three of the patients died, all of them from mitral stenosis and auricular fibrillation (11.1 per cent.).

There is a general feeling that, apart from myocardial failure, mitral stenosis is the cardiac lesion which gives rise to the greatest danger in pregnancy, both during and after parturition. In mitral stenosis there is the possibility of auricular fibrillation and its accompaniment—diminished heart output. H. R. Schmidt,[3] dealing with the subject of heart failure in pregnancy, reminds us that many patients are unconscious of the fact that they are the subjects of heart trouble until after parturition. Baisch examined 200 patients. He found that 50 per cent. of the women remained well, 45 per cent. suffered from failure of compensation, and that 5 per cent. died. Schmidt reported 38 cases of heart failure in 10,027 patients (0.38 per cent.): 5 of these died in hospital during the puerperium, and 5 within a year and a half after parturition. Of 12 patients with mitral stenosis, 6 died immediately after labour, the most serious cases being those with signs of myocardial degeneration, attended by irregularity of the pulse and stasis of the circulation. In heart disease and pregnancy we have to remember that the function of the heart is less deranged by the mechanical conditions incidental to pregnancy than by the consequences of decompensation—that is to say, failure of compensation where there is a valvular lesion. Failure of compensation may occur even in the early months of pregnancy and be the result of inability on the part of the heart to deal with the increasing volume of blood, so that in consequence of embarrassment of the organ the question of the advisability of terminating the pregnancy may have to be considered.

It is difficult to obtain statistics of large numbers, for, after all, the cases are comparatively few, varying from 0.38 per cent. in Schmidt's experience to 1.06 per cent. in G. A. Wagner's; and while we cannot but admit that heart disease in pregnancy is a serious complication, yet here again, as to its seriousness, reliable information is scanty. Wagner's cases numbered 80 in 8,000 pregnant women: 14 of these 80 women died directly or indirectly of heart lesions, but in 12 of these 18 women pregnancy had to be terminated as they were showing such signs of failure of cardiac compensation as cyanosis, dyspnoea, small radial pulse, tachycardia, and prostration. In many of the cardiac patients treated in the Princess Mary Maternity Hospital the second stage of labour has been rapidly gone through, sometimes occupying not more than five minutes, so that, owing to the comparatively rapid emptying of the uterus and the fall in the abdominal pressure, there is a rush of blood to the splanchnic vessels, with the possibility of fatal cardiac failure, such as has been known to occur shortly after surgical removal of a large ovarian cyst.

Heart Disease and Marriage.

Since heart disease may become a serious complication of pregnancy, we are occasionally consulted as to whether women who are its subjects should marry and thereby incur the risk of pregnancy, with its attendant dangers. There will always be a certain number of married women who do not become pregnant, but in the circumstances of a normal married life there is the possibility. Our experience is that while a cardiac patient may pass successfully through two or three pregnancies and be little the worse for the event, yet with each succeeding pregnancy the heart becomes less and less able to bear the strain—it dilates, and its musculature becomes less efficient. There is always the tendency, too, for the pulmonary circulation to become embarrassed, especially where the lesion affects the mitral orifice. When a single woman has already suffered from haemoptysis and dyspnoea, these circumstances of themselves should be a reason for the discouragement of marriage. Professor Peter of Paris was of the opinion, in view of the pulmonary complications which were likely to arise, that women with heart disease should not marry, but one of his contemporaries, Professor Jacoud, regarding the statement as too sweeping, maintained that at any rate many women could pass successfully through three pregnancies, including one or two miscarriages, without their health becoming seriously impaired. When, therefore, our advice is asked, we must carefully consider the condition of the heart, the presence or absence of dilatation of the organ, also the regularity and rapidity of its beat, the history of haemoptysis and dyspnoea, as well as the social and economic status of the patient and her prospects. Irregularity of the heart's action is one of the main dangers to pregnant women. It was the sudden death of a young expectant mother during parturition which led Sir James Mackenzie, when a general practitioner in Burnley, to study more assiduously diseases of the heart. The real danger of heart disease in pregnancy, he too thought, was not so much the existence of a particular valve lesion as the condition of the myocardium. Mackenzie regarded breathlessness and pain as indications of failure of the heart to respond effectively to effort, and he added that these are really not heart symptoms at all, but are produced outside the heart, in the lungs and nervous system.[4]

The Danger of Pregnancy to a Woman with Damaged Heart.

Apart from the effects of previous endocarditis caused by rheumatic fever, intracardiac conditions may arise during pregnancy which may render the organ incapable of carrying the patient through parturition and the puerperium. Although cardiac irregularity was the predominant feature in the Burnley patient just alluded to, it became clear to Mackenzie that there must be various types of irregularity, and that all are not equally dangerous. It is common knowledge that some women with irregularity of the heart's action can pass through the processes of parturition with apparently no ill effects, while in the case of others life is seriously endangered or suddenly brought to a close.

Recent advances in cardiology have confirmed the views, more than once expressed, that life is mainly threatened by myocardial conditions, and in these are included changes in the sino-auricular node, auriculo-ventricular node, and the bundle of His. Such secondary effects as pulmonary congestion and right-sided cardiac dilatation are also of importance. I need only briefly mention the two special nodes of tissue, the sino-auricular node close to the base of the auricles, also the auriculo-ventricular with the bundle of His running down in the myocardium and dividing into two branches, one for each of the ventricles. The impulse to rhythmic cardiac contraction originates in the tissue of the sino-auricular node, and is transmitted by the muscular fibre of the auricular walls to the auriculo-ventricular node, and therefrom by the bundle of His to the ventricular walls. The heart is supplied by branches of the vagus and the sympathetic system of nerves; branches of both of these reach the sino-auricular node, also the auriculo-ventricular, while the substance of the cardiac muscle is capable of originating beats of its own. When through disease the sino-auricular node ceases to function the auricles pass into a condition of fibrillation, but the ventricles still continue to beat at a rate and with a rhythm special to themselves. One of the results of alteration in the rhythmic discharge of impulses from myogenetic and cardiac nervous mechanisms is the occurrence of extra-systoles or of tachycardia. The

former may be traced to defaults in (1) auricles, (2) auriculo-ventricular node, or (3) the bundle of His and its branches. An extra-systole is but a single contraction due to the impulse which produces it being discharged earlier than those normally emerging from the sino-auricular node. On the other hand, what is meant by "heart-block" is an irregularity of rhythm due to some defect in the auriculo-ventricular node, or the bundle of His, whereby impulses from the sino-auricular node are not conveyed to the ventricles, and as a consequence the ventricles commence to beat spontaneously.

Cardiac Lesions Separately Considered.

The cardiac lesions met with in women are mostly mitral stenosis and regurgitation—especially the former. It is the effects and the associates of this lesion which obstetricians find play such a harmful part in the later months of pregnancy, also during the second stage of labour and afterwards. As the end of term approaches, the uterus has risen high up in the abdominal cavity, the movements of the diaphragm are impeded, for the midrib cannot contract so well as formerly, and as a consequence there occurs increased venous pressure towards the heart, with circulation stasis, attended by cyanosis and a degree of dyspnœa. The flow of blood through the right heart is delayed. In mitral stenosis in a non-pregnant woman there is usually dilatation of the left auricle and an overfilling of the pulmonary capillaries, followed by compensatory changes in the right heart. That such occur similarly in pregnant women is shown by the fairly free haemoptysis observed in many women prior to the onset of labour. When the breath is held in inspiration during the expulsive stage of labour, and the abdominal and uterine muscular contractions are strong, and when it almost seems as if the right heart could hardly empty itself, relief is brought to the overdistended organ by impulses carried centralwards by the vagus from the overfilled auricles through acceleration of the cardiac beat. The impulses referred to induce, as Bainbridge experimentally demonstrated, cardiac quickening, either by reducing the tone of the cardio-inhibitory mechanism, or by throwing the cardio-accelerator nerve centres into action. By means of this cardiac reflex there is not the least doubt that much maternal suffering and impending danger are averted.

A similar remark applies to mitral regurgitation. Instead of having, however, a small left ventricle, as in cases of uncomplicated mitral stenosis, this chamber is hypertrophied and dilated. The condition enables the heart to cope with the increased quantity of blood poured into it during diastole, so that in pregnancy, given a heart in which compensation is well established, the patient may pass fairly comfortably through the ordeal of parturition; but if, on the other hand, the mitral reflux is fairly free, there will be a degree of backward pressure towards the lungs with inefficient emptying of the right heart, so that the secondary effects come to resemble those met with in mitral stenosis.

In aortic regurgitation it is the left ventricle which claims our attention. Whatever may be the degree of blood pressure during quiescence before the onset of labour pains, the subsequent uterine contractions and those of the abdominal muscles induce a rise of the general arterial tension, and while Marey taught that increase of arterial pressure is followed by slowing of the pulse, this can hardly be said to be quite true of events occurring in the second stage of labour. As already mentioned, during the expulsive stage of labour the breathing is suspended in the inspiratory phase, and this, in conjunction with the muscular contractions, causes an increased flow of venous blood to the right heart. It is then that the Bainbridge reflex comes into play and, by accelerating the pulse rate, tends to maintain the output per beat of the left ventricle at its normal value. Nature has thus provided against serious overdistension of the heart by quickening the pulse and shortening the diastolic period. More and not less blood will thus be expelled from the left ventricle, and the circulation through the coronary arteries, which is the essential requirement, will be maintained. This is probably the explanation of how patients who are the subjects of aortic regurgitation pass through pregnancy and parturition with less risk than might be expected. In aortic incompetence the left ventricle is hypertrophied and dilated, so that the heart of a pregnant woman accommodates itself to the increased inflow and acts in accordance with Starling's "Law of the heart," whereby the energy set free by the cardiac muscular fibres when they contract varies in proportion to their muscular length. When, therefore, in aortic regurgitation with hypertrophied left ventricle the elongated muscular fibres contract they liberate more energy, there is greater endocardiac pressure, the aortic valves open earlier, the period of expulsion is probably lengthened, and the pulse quickened.

Time will not permit me now to deal with the development of heart affections after the menopause, yet probably related to child-bearing.

Treatment.

The treatment of the pregnant woman with heart disease resolves itself into treatment during pregnancy, parturition, and the lying-in period. If the cardiac lesion is well compensated, and there is no embarrassment of breathing—if, in a word, the patient differs in no respect from a healthy woman similarly circumstanced, then all that is necessary is to keep her under observation, diet her, regulate her exercise, and keep the emunctory organs in good condition. If the blood pressure remains in harmony with that of the average of healthy women, the chances are that the patient will pass through pregnancy and the puerperium without risk. The cases which make us anxious are those in which towards the end of pregnancy the pulse becomes rapid, feeble, flickering, or irregular, but even for such patients much can be done by keeping them in bed and giving digitalis in increasing doses if required. The first stage of labour, if not unduly prolonged, may not be more oppressive than in other patients, although the accoucheur must be on the lookout for signs of fatigue. It is the second stage which calls for careful attention on the part of the obstetrician, so that he may shorten it by the application of the forceps, if there are signs of fatigue or of cardiac failure; or if there is difficulty of breathing, that he may administer oxygen and give hypodermically strophanthin, digitaline, or strychnine, and on the expulsion of the placenta see that abdominal pressure with the hand is maintained. The anxiety of the accoucheur is considerably relieved once parturition has been successfully passed through, but, during the lying-in period, cardiac patients, particularly those with mitral stenosis, require watching for a week or two.

It is desirable that the women of the working classes, particularly those who are the subjects of heart disease, should, if they become pregnant, report themselves at an ante-natal clinic, and, before the end of term, enter a maternity hospital, where, under the supervision of a resident medical officer, eventualities of all kinds may be anticipated and dealt with. I can speak most encouragingly of the good results which have accrued from following out this recommendation. In a general way, even women who are believed to be healthy would benefit, where circumstances permit of it, by reporting themselves at an ante-natal clinic one month before the expected termination of their pregnancy. Where there is no clinic or maternity hospital close at hand a woman who is the subject of heart disease should certainly see her own doctor shortly after she believes herself to be pregnant, and obtain from him advice as to what her line of life should be, what she ought and what she ought not to do; for if her condition, cardiac and general, is such as to cause anxiety and is likely to be attended by risk to her own life, the doctor might, by keeping her at rest at home and treating her with heart tonics, help to carry her safely through her confinement; or—and this might often be better—arrange for her admission into a maternity hospital, where she would have the prescribed rest and medical attention. A pregnant woman with heart disease need not wait until "quickening" takes place before reporting herself to a doctor.

An Address
ON
PROFESSIONAL REGRETS.*

BY
HENRY RUSSELL ANDREWS, M.D., B.S.LOND., F.R.C.P.,
CONSULTING OBSTETRIC PHYSICIAN, LONDON HOSPITAL.

I WAS asked some months ago to take part in a discussion on "Professional regrets," and agreed to do so. A fortnight ago I was rather staggered by a request from your secretary that I should open the discussion—a very different matter. I take it that my duty is to say a few words on each of a series of subjects that may be discussed by those who follow me, and to point out traps for the unwary. I hope that none of my remarks may give any offence. If they do I shall have added yet another to my professional regrets.

Pre-cancerous conditions or very early carcinoma of the uterus.

A case which caused me very great regret was the following:

A woman, aged 57, three years after the menopause, had had for about a year a good deal of vaginal discharge, with sometimes slight bleeding on douching. The vaginal mucous membrane was normal, the external os small, virginal. There was a small, raw-looking patch on the vaginal portion of the cervix. The body of the uterus was distinctly enlarged. I could not cause even the slightest oozing of blood. I wanted to explore the interior of the uterus, but she was a very busy woman, and begged to put it off. She promised to let her doctor know, and to submit to dilatation of the cervix and exploration of the interior of the uterus, if there was any return of bleeding. I heard nothing more of her for thirteen months, when she came back to me. She had quarrelled with her doctor soon after I saw her, and had seen no other doctor, in spite of having had practically continuous slight bleeding ever since I saw her. I found that she had extensive carcinoma of the body of the uterus. I regretted that I had not insisted on her having the interior of the uterus explored, even if it meant telling her that I feared malignant disease.

This was rather an exceptional case. I have generally found that, if a patient gives a definite promise that she will come back if symptoms recur, one can rely on her to do so, but there is always a danger of a patient changing her doctor and telling the new one nothing. I very much regretted that I had not been firmer with this patient.

Not examining under an anaesthetic.

If one does not feel reasonably certain about a patient's condition one ought to insist on an examination under an anaesthetic. This is almost axiomatic. In hospital practice examination under an anaesthetic is an everyday occurrence, and one has often had two or three examinations under anaesthetics at the end of a long operation list, but it is not always easy to insist on in private practice. It is specially important in any painful or acute abdominal trouble occurring during pregnancy when one is handicapped, not only by the tenderness, but by the presence of a large tumour. One ought to insist on an anaesthetic, and to say that one is so much handicapped that a definite opinion cannot be given without it. In one case in which I thought that the patient was suffering from red degeneration of a fibroid during pregnancy I foolishly agreed to a policy of "wait and see," as she was tremendously keen on having a living child and afraid that any interference, however slight, might bring the pregnancy to an end prematurely. I waited too long, and found eventually that the "tumour" which I had noticed was due to volvulus. Examination under an anaesthetic two days earlier would have shown that the tumour had no intimate connexion with the uterus, and would have led to immediate and probably successful abdominal section.

Another case in which I ought to have examined under an anaesthetic is worth quoting at some length.

In 1906 a patient, aged 31, came to me for advice about an abdominal tumour which had been diagnosed by her own doctor and by a well known gynaecologist as uterine fibroids. There were two large, hard, round swellings, one behind the uterus and the other on top of the lower one, reaching up to 1½ inches below the umbilicus. She had no symptoms of any sort. I agreed that the tumours were uterine fibroids, and told her that operation would probably be necessary later, but was not specially indicated at that time. In 1914, eight years after I had first seen her, she was seized with abdominal pain. I opened the abdomen, and found that each tumour was an extraordinarily large pyosalpinx, filled with a putty-like matter, infected with *B. coli communis*. The right one had just begun to leak. I left both ovaries and the uterus behind. She made a perfectly smooth recovery, and is in excellent health now, but I felt that I had let her run an absolutely unnecessary risk. A history of an illness at the age of 6 suggested that she had had tuberculous peritonitis, and that the tubal trouble was tuberculous in origin.

Not having the rectum and bladder emptied in a difficult case.

I think that regrets connected with full bladder and imperfectly emptied upper part of the rectum and sigmoid colon are probably associated with early days in practice, because most men learn then the dangers of the bladder-and-faecal-masses-trap and avoid them carefully afterwards. In the women's medical wards at the London Hospital there was for some years a rule that if a request note was sent to me to see a patient she must be given an enema at once, before I came, as otherwise I should probably say that I refused to give an opinion until this had been done. I was once just saved from opening the abdomen for what seemed to be the most perfect case of cornual pregnancy that I have ever seen. The rectum was empty when I saw her, but she was given an enema later because she was to have an operation. The doctor was so much struck by the aged appearance of a scybalous mass removed by the enema that he asked me to examine her again before she went to a nursing home. I did so and found a normal pregnancy. I was brought up to empty the bladder and to examine per rectum in every doubtful case, and this early training has saved me from many regretful occurrences, though once, to my shame, I opened the abdomen for a bladder which had been distended for at least a fortnight in a medical ward. I can only plead that I was very young at the time, but I was old enough to have known better, in spite of regular micturition. The value of routine rectal examination was well shown by one case in which I was asked to give an opinion. I examined the patient and said that she had two large hard faecal concretions in the rectum. I was then asked, "What about the uterine fibroids?" I said, "She has not got any." The retort was, "She is going to have abdominal hysterectomy for fibroids to-morrow." The upshot was that I removed the faecal concretions with a lithotomy scoop and she was allowed to keep her uterus.

Induction of premature labour.

Here again I may get myself disliked, but I cannot help it. I have been asked to talk about professional regrets, and I must be truthful, nothing extenuating nor setting down aught in malice. *The* essential after induction of premature labour is that nature should be interfered with as little as possible, any unnecessary intervention being likely to be dangerous to the life of the infant. Artificial rupture of the membranes, because the progress is slow, is a most dangerous procedure. The head is not meant to act as a dilator of the cervix—the bag of membranes is there for that purpose—and the head ought to be spared any unnecessary pressure. Delivery with the forceps three or four weeks before term, unless only by gentle coaxing, is a dangerous procedure, as an amount of compression that would do no harm to the fully ossified skull may cause fatal damage to the imperfectly protected brain, while moulding due to the natural forces, spread over a few hours, is unlikely to be harmful. If one does not know from experience that the patient's doctor in the country is a man with sufficient knowledge of midwifery to look on, to treat the labour with masterly inactivity—in other words, a man who realizes that patience is the most important quality in the make-up of an accoucheur—it is one's duty to insist on the management of the case oneself. Do not think that I often insist on this; on the other hand, I have never done so, but I have twice regretted it deeply, as the

* The opening paper in a discussion at the Chelsea Clinical Society.

baby was killed by unnecessary use of the forceps before the natural forces had been given a chance. What I regretted was that I had not rubbed in the virtues of patience—a difficult thing to do when dealing with a man who had probably attended more confinements than I had. I have sometimes regretted that I had not induced labour prematurely, but I have never regretted inducing it. I think that it is a method of immense value in the treatment of minor degrees of contraction of the pelvis.

Not giving sufficiently definite instructions as to treatment after operation in strange nursing homes.

Surgeons are sometimes accused of being fussy and disobliging because they are unwilling to perform severe operations in any nursing home which they do not know well. They ought not to be blamed for this, as it is usually done entirely in the interest of their patients. I have several times regretted that I had gone to a strange nursing home at the request of the patient or her doctor. In one case I performed Wertheim's hysterectomy for extensive carcinoma of the cervix in a very fat woman. We left her in a warm bed in a warm room at 10.30 a.m. with a good pulse, and the doctor, the anaesthetist, my assistant, and myself were all very well satisfied with our work and considered that the patient had at least a 20 to 1 chance. I was telephoned to soon after 2 p.m. and told that the patient had died suddenly. I went straight to the home and was told that the patient came round well from the anaesthetic, with a good colour and a good pulse, and that as she was rather restless and uncomfortable they propped her up in bed with four pillows. Directly after they had propped her up she died suddenly. Was this to be wondered at when she had just had a severe operation, and had been in the Trendelenburg position for about an hour and a quarter?

I was rung up a few hours after a hysterectomy during pregnancy, and told that the patient was very much collapsed and that they were very anxious about her. I was too far away to get there in time to do anything, so I asked about her position, and was told that she had two pillows. I said that they must be removed and the foot of the bed must be raised. A few hours later I was told that her condition was excellent. In any of the homes in which I am accustomed to operate the first patient would probably have lived and the second would have caused no anxiety, as common-sense after-treatment would have been looked on as a part of the nurse's duty, and I should have known that all the nurses were competent; but in these two cases I regretted that I had not given definite instructions, even at the risk of causing offence to an experienced nurse. In strange nursing homes I have sometimes regretted that I had not inspected the patient's room before the operation. If I had done so the patient would not have been taken from a warm theatre, on a cold day, to a room with a miserable fire and both door and windows open. One may find the patient before operation, clad in a Gamgee jacket and a dressing-gown, with thick stockings on and a blanket wrapped round her thighs and legs, enjoying the fresh cool air, but during the operation the bed and the room ought to be warmed thoroughly.

On another occasion my anaesthetist helped to take a patient back to bed, removed several hot-water bottles, and said that they were not to be replaced until she asked for them. I followed him up and repeated his instructions. When I inquired from her doctor a few days later about her progress he said, "She has done very well, but she has a horrible burn over almost the whole outer surface of her right upper arm and forearm." I said, "How on earth could she get burnt when both my anaesthetist and myself made certain that no hot-water bottle was in the bed?" He answered, "Oh, soon after we had all gone they put a hot-water *bed* under her!" Some people consider that a nurse is a nurse, and do not agree that there are nurses and nurses, and even in a fairly good home one may find on inquiring that a special nurse, an absolute stranger, has been engaged to look after the patient, arriving about an hour before the operation and allowed to act on her own responsibility. If this is found out in time very definite instructions indeed are given, feeling one's way so as not to give offence if the nurse is competent; but if it is not found out in time there may be many regrets. There is the very uncomfortable feeling that the patient has put herself in one's hands, and that one has let her down if all the arrangements are not perfect.

Not taking one's own anaesthetist and assistant to a difficult case.

I realize that I am treading here on rather dangerous ground, but feel that I ought to have the pluck to say something on this point. I wish to say first of all that among my general practitioner friends are some of the best anaesthetists and assistants with whom I have the privilege of working; but there are others! An anaesthetist is born, not made. I have had perfect anaesthetics given to my patients by newly qualified men of very small experience, and have laboured, toiled, and been filled with anxiety and dread as to the immediate and after results of anaesthetics given by men who have studied the matter deeply and done their utmost to improve their skill in the art of inducing anaesthesia. To insist on having one's own anaesthetist may require some moral courage, and may give offence, but it is one's duty to stand out for it if it be considered, from past experience, that the patient's safety is jeopardized. The difficulty of the operation, especially if it entails deep pelvic work, is enormously increased if the patient strains and coughs throughout, and the wear and tear to the operator is doubled or trebled if he has intestine shooting into the pelvis whenever he has a sharp instrument inside that cavity. Apart from the increased danger of the operation, the patient will suffer far more from vomiting, distension, and abdominal discomfort during the first few days, and will run risk of bronchitis. When I have been weak enough to accept a second-rate anaesthetist or assistant I have regretted it bitterly, because of the exhausting fatigue and anxiety caused to myself, even although my anxiety about the patient has been of short duration as I heard that she was doing very well. Team work produces the best results, and the operator ought not to have to worry about the anaesthetic, or about the asepsis of his assistant. To look up in the middle of a difficult job and see his assitant arranging, with his gloved hands, his spectacles and the mask through which he has been breathing for half an hour, adds greatly to the worries and anxieties. Unlike the art of inducing anaesthesia, an aseptic technique is never inborn, but has to be learned by experience and instruction. I think that some men who do not operate themselves are rather inclined to consider an operator to be fussy and neurotic if he expects an anaesthetic to be perfectly given, and that he ought not to take it as more than a "rub of the green" if gag, tongue forceps, and throat swabs are used throughout, with artificial respiration only at infrequent intervals. This sort of anaesthetic would not matter much if a toe was being amputated; it is not only disconcerting but really desperately dangerous in abdominal and pelvic surgery. I have not really had much to complain of recently, as most men are very sensible on these points, but I have had some regrets in the past.

Not reopening the abdomen soon enough when symptoms of intestinal obstruction come on a few days after an abdominal operation.

Intestinal obstruction is not as common after gynaecological operations as it was formerly, because an attempt is always made to cover up with peritoneum any raw surface or stump and to prevent any oozing after operation, but in some cases, particularly old pyosalpinx cases, it is difficult to find any peritoneum loose enough to be sutured over a raw surface. I can remember five cases of intestinal obstruction after operation. The first was after myomectomy from the posterior surface of the uterus. Practically the only symptom of which the patient complained was pain. As she was having a monthly period, and always had severe dysmenorrhoea, I was deceived, and delayed opening the abdomen for too long, and she died

soon after the second operation, in which a coil of small intestine was freed from an adhesion to the suture on the uterus. Delay is most dangerous, if not fatal, in such a case. The surgeon has a natural objection to reopening the abdomen, and is tempted to delay and hope for the best, but the proper treatment is to harden one's heart and explore as soon as suspicions are aroused. The other four cases—in three of which I had performed the first operation myself, while in the fourth the first operation had been performed by one of my colleagues—were ovariotomy, pyosalpinx with terrible adhesions, pyosalpinx, and severe bleeding from an ovary. Profiting by my experience in the first case I lost no time in operating on these four, and they all recovered. I have never ceased to regret that I had not sufficient common sense to explore the abdomen of the first patient as soon as she looked ill and complained of pain, as, if I had done so, she would almost certainly have lived, as the adhesion was easily dealt with.

Not strapping the abdomen when a patient has a cough during the first fortnight or so after an operation.

I have regretted bitterly that I had not reinforced the stitches, or the recently united tissues after removal of stitches, by carefully applied strapping, when a patient has developed a cough after an operation. If the cough is violent the abdomen is strapped almost as a matter of routine, but it is important to remember that a patient who has a mild, fairly harmless cough may cough violently once or twice when she wakes up after several hours' sleep and finds some tenacious mucus in her throat, difficult to dislodge. I can only remember two cases in private practice in which patients have burst the wound open by coughing. I ought to have strapped the wound in both, and have regretted ever since that I did not do so. One patient died a fortnight later, the other recovered.

There are some cases in which I have had *no regrets*. In some of these I have told a patient that in my opinion no operation was necessary, and have later heard that she went on to someone else, who sent her into a nursing home immediately and operated the next morning. I find that I spend a good deal of my time in advising patients to avoid operations. Some of them are exceedingly grateful, but some go straight to another man. One case in which I was given most fulsome thanks may be worth a detailed account as showing how difficult it is to prophesy what a patient will do.

A man, whom we will call Mr. H., rang me up on the telephone and said, "What would you charge to operate on my wife?" I naturally said, "What is the matter with her?" He answered, "It is the womb." I said, "I am afraid that I cannot give an opinion without seeing your wife." He replied that he thought that I would be able to suggest a fee without seeing her, so I said, "If you telephoned to a bootmaker and asked how much he would charge to mend your boots, would he not say, 'Let me see your boots?'" "Doctor, there is something in what you say; I will bring my wife to-morrow." I examined her, a multipara of 54, some years after the menopause, with a very loose abdominal wall, backache, and dragging sensation, with several small fibroids and retroversion of the uterus. She had seen many gynaecologists in Germany, some of whom had advised operation while others had advised against it. The patient said that she wished to avoid an operation. I suggested that an abdominal belt might give her a great deal of comfort, and she said that she had had one which had done her a lot of good, but it was worn out. The husband said, "Doctor, you are a British sport. Before the war I used to say, 'Go to the Continent for an opinion,' but since the war I say, 'No, stick to your own men!' No one has asked the questions that you have asked, no one has taken so much trouble, no one has suggested a belt. Doctor, I thank you, you are a British sport; we will go and get a belt." Two days later I met a medical friend who said, "You remember Mrs. H.?" I said, "Yes, she's going to try an abdominal belt." He said "No; she went on from you to Y, and then to Z, who put her straight into a nursing home and operated on her yesterday morning!"

TREATMENT OF ENCEPHALITIS LETHARGICA BY THE REMOVAL OF POSSIBLE ETIOLOGICAL FACTORS.

BY

GEOFFREY EDEN, M.D.CAMB., M.R.C.P.,

AND

A. LOWNDES YATES, M.D.LOND., F.R.C.S.ED.,

SURGEON, EAR AND THROAT DEPARTMENT, GENERAL HOSPITAL, WOLVERHAMPTON.

PART 1, BY A. L. YATES.

SOME four years ago I began an investigation of the nasal ciliary mechanism, and found that the ciliated epithelium formed definite tracks which functioned in a backward direction so that mucus rolled over any particles introduced within the nose, and conveyed them backwards into the nasopharynx along certain definite paths.[1] This led to a further investigation of the ciliary and secretive mechanism, and the nasal mucous membrane in inflammatory states, and it was found that four groups of conditions could be observed—namely:

1. Those in which mucous secretion was excessive and the cilia active.
2. Those in which mucous secretion and the cilia remained active, and to the mucus was added serum and leucocytes, forming yellow muco-pus. In neither of these conditions was there any alteration in the staining power of the mucus, nor could the micro-organisms which were visible microscopically in the mucus be cultivated.
3. A condition in which the mucus became altered, apparently as a result of the action of the bacterial ferments, so that the mucus stained with aniline dyes, such as indigo-carmine. In this group cases were met with where the cilia were more than normally active, and where the mucus was conveyed backwards into the nasopharynx, causing in and around its path a chronic inflammation of the mucous membrane, and thus producing laryngitis, tracheitis, and oesophagitis. In another group of cases the cilia were less than normally active, and the altered mucus remained in the sinuses and in the nose. In Types 1, 2, and 3 an anterior nasal discharge appeared when mucus or muco-pus was greater in amount than the cilia could convey away into the nasopharynx.
4. In this group I found cases in which the cilia and mucous secretion were paralysed, so that the organisms which can often be obtained in pure culture from the interior of the sinus were present in a brownish watery solution containing the remains of leucocytes—that is to say, of water-soluble pus.

Certain cases in Group 4 showed the presence of toxic absorption and suffered from various complaints, such as periarticular rheumatism, neuritis, neurasthenia, skin complaints, and similar conditions. Other cases in this group showed no such signs of toxic absorption.

In order to determine the reason why some of the cases in this group had toxic absorption and others not, a solution of 0.4 per cent. indigo-carmine or 0.01 per cent. phenol-sulphonephthalein was placed in the sinus. In the cases which showed signs of toxic absorption of nasal origin this dye appeared in the urine in from ten to fifteen minutes. In cases without toxic absorption, or in cases in which the sinuses were all relatively normal, or if swallowed, the dye did not appear in the urine.

Toxic absorption from the mucous membrane would therefore appear to be prevented in the early stages of inflammation by mucous secretion, and in the late stages by deposit of fibrous tissue.

The Nasal Condition in Encephalitis Lethargica.

Various writers on encephalitis lethargica have drawn attention to the presence of nasal and buccal discharge in practically all cases, and I found paralysis of the cilia and mucous secretion in fully developed cases in the posterior portion of the nose—that is to say, in the ethmoidal recess, the posterior ethmoidal sinuses, or the sphenoidal sinus—and that such inflammation tended to spread both forwards to the mucous membrane of the nose

and downwards to the mouth, causing an excess of mucous secretion in both these situations.[3] The dye, if it could be placed in the affected area, appeared in the urine in about fifteen minutes.

This condition could be brought about either by a single acute nasal infection of the type known colloquially as influenza, in which it could be demonstrated that the mucous membrane of the nose passes in a few days, or even hours, from the normal to a condition of paralysis of the cilia and mucous secretion with toxic absorption, or by a chronic inflammation producing a like result in months or years. Cases of encephalitis lethargica give a history which will correspond either with an acute attack of influenza or a chronic type of nasal infection, but due regard is to be paid to the fact that both influenza and chronic rhinitis are very common conditions.

Dr. Stanley Barnes[3] made the suggestion that it was this permeability of the nasal mucous membrane which permitted the virus of encephalitis lethargica to enter the tissues and to reach the nervous system, probably by the perineural lymphatics. A critical review of this work appears in the *Bulletin of Hygiene*.[4]

Treatment of the Nasal Condition in Encephalitis Lethargica.

It was clear that if this hypothesis was correct any treatment which diminished the permeability of the mucous membrane to toxins would have the effect of diminishing the absorption of the virus of encephalitis lethargica into the tissues, but that it would have no effect upon any areas in the brain already destroyed by the virus, and therefore that the most that could be expected as a result of such treatment would be that in chronic cases recrudescences of the disease could be prevented, and in acute cases at best the damage to the brain could be limited to such areas of damage as had been total and had occurred before sinus treatment was adopted.

Method.

The nasal mucous membrane having been anaesthetized by spraying with 5 per cent. cocaine in 1 in 1,000 adrenaline, a cannula of a diameter of a millimetre or less and suitably curved is, under direct vision, passed over the middle turbinate and thus to the front of the sphenoidal sinus. On rotating the cannula gently the end can be felt to slip into the sphenoidal sinus; a syringe is then attached and by suction some of the contents withdrawn for cultivation. The sinus is then thoroughly washed out with saline. The posterior ethmoidal sinus can also in some cases be reached. In a certain number of cases even with full cocainization it is not possible to pass a cannula between the middle turbinate and the septum; it is then necessary to pass the cannula beneath the middle turbinate and thus reach the spheno-ethmoidal recess. By this route the sphenoidal sinus can occasionally be reached, but this is not generally the case.

Treatment consists of giving a vaccine in increasing doses and washing out the sinuses again if the patient ceases to improve. Improvement on washing out the sinuses is often marked, generally after a few days, but the patients tend to relapse, and on the average the washing out must be repeated every month or six weeks. In addition to the above the patient uses a douche consisting of menthol 2 grains, eucalyptol 20 minims, and liquid paraffin to 4 ounces. A medicine dropper full is injected into each nostril three times a day while lying on the back with the head thrown well back.

Relative Value of Various Treatments Used.

It is difficult to arrive at a conclusion as to whether the washing out of the sinuses or the use of vaccines produces the greater effect, but many patients have stated that the most marked improvement has followed the washing out. It appears to be doubtful whether an autogenous vaccine produces more effect than simple protein shock, but an autogenous vaccine has been given in all patients who were the subject of this investigation. In those who gave a history of chronic and intense rhinitis for some years bacteriological examination showed either the bacillus of Friedländer or the pneumococcus; in those in which encephalitis lethargica followed an acute or influenzal rhinitis the *Staphylococcus aureus* alone or together with the pneumococcus was generally found.

The postural deformity of encephalitis lethargica has apparently some bearing on the course of the more chronic forms of the disease, for patients in whom the postural deformity is not dealt with by remedial exercises appear to reach a stage in which, although the mental symptoms, etc., have ceased, the patient still has a Parkinsonian gait and posture.

For a year all patients have been taught exercises, which they do in their own homes, or, in the more severe cases, under the guidance of a masseuse; these exercises have effected a marked improvement in their condition, both in preventing the ready fatigue from which these patients suffer, and in enabling them to get rid of the difficulty in balancing which is such a marked feature in many, so much so that it has seemed that in the patients in whom imbalance was most marked the faulty position of the labyrinth relative to the remainder of the body was a factor in the production of symptoms. The exercises, in addition, train to the highest point of efficiency such nervous structures as remain undamaged, and thus reduce the deformity caused by a deficient action of the areas of the brain which have been destroyed.

PART II, BY G. EDEN.

The diagnosis of many cases of epidemic encephalitis in the acute stage is often very difficult, and in the less severe cases of a chronic nature must be a matter of opinion, as, up to the present, we have no means of absolute proof of the correctness of the diagnosis. But there can be little doubt in those cases in which Parkinsonian symptoms develop, either after an acute febrile illness with gross disturbance of sleep, paresis of an ocular muscle, diplopia, or loss of accommodation and retention of the light reflex.

Though the Parkinsonian form of encephalitis lethargica is the most liable to be progressive and the most resistant to treatment, our description of the results of washing out the sinuses in the chronic cases has been limited to cases of this type. One advantage of this limitation is that almost all the patients had previously had several, if not all, of the many treatments usually advocated for the sequelae of encephalitis—for example, tonics, belladonna, massage, hyoscine, protein shock, etc. The only essential difference in our treatment has been the washing out of the sinuses, and the regular use of nasal antiseptics, but the majority had weekly doses of an autogenous vaccine prepared from the organisms found in the sinuses. The washing out was repeated in many cases, a return of drowsiness, headache, and apathy being the usual indications.

Striking and immediate improvements were often observed as a result of the first washing out, and patients generally volunteered the statement that the washing out of the sinuses caused greater improvements than the use of vaccines. The fact that almost any new treatment for encephalitis often produces a short temporary improvement has not been lost sight of, and the writing of this paper has been delayed until the effects of washing out the sinuses had been observed for a period of at least three months in any one case; in the majority of instances cases have been observed for over a year after treatment was begun.

It is not claimed that this is a cure, but it appears to us to be a remedial measure of great value in association with drug treatment; where drugs alone have been useless, a washing out, followed by the same drugs, often produced a good effect.

The frequency with which patients relapse, and the fact that these relapses are improved or prevented by one or more washings out, suggests that the absorption of toxins is interfered with, and to a great extent prevented, by disinfection of the nasal mucous membrane. The usual results of washing out the sinuses has been almost immediate improvement in the patients' symptoms. They feel brighter, find themselves capable of doing more for themselves in their homes, become less rigid, and the face becomes less mask-like. There has seldom been any marked improvement in the mental condition of the chronic cases.

The following are typical of the results obtained in many chronic cases.

Case 1.—A woman, aged 23; an extreme case with well marked Parkinsonian symptoms. Two years earlier she had had an acute illness with great drowsiness, and diplopia followed by rigidity of all limbs. A year ago she was considered a hopeless case by several competent authorities; for six months she had been unable to feed herself, and for over a year had not been out of bed.

Four days after a washing out she was able to feed herself slowly and with difficulty, and three weeks later she walked out of hospital. Her expression was less wooden, though all muscles were still spastic.

Case 2.—A woman, aged 19, with a history of acute febrile illness eighteen months earlier, with extreme insomnia, sialorrhœa, and marked alteration in character. She had a well marked Parkinsonian mask. All movements were slow and stiffly performed. She improved in all respects after the sinuses were washed out. She regained normal sleep, salivation decreased, and her expression was less wooden.

Case 3.—A woman, aged 23, who two years and nine months earlier had an acute illness; she was unconscious for twelve weeks. When first seen she had much salivation, was very lethargic, had a mask-like appearance, and was said to have violent fits of temper. She was discharged from hospital after a washing out; a month later she was much improved in appearance, both mentally and physically. Her bad temper became less obvious, the salivation was cured, and her whole outlook on life seemed altered.

Case 4.—A woman aged 23. A very advanced case dating back two years. It would be difficult to imagine greater rigidity of all muscles. She was unable to stand or to feed herself and could hardly speak. She had seen twenty-eight medical men before she came to us. A washing out caused a rapid and definite change in her condition. Four months after discharge from hospital she could walk two miles a day—doing the distance in less than an hour—could feed herself, and read aloud for an hour at a time.

Case 5.—A male, aged 24, in March, 1923, had an acute febrile illness lasting three weeks, with severe insomnia, diplopia, and delirium; no diagnosis was made at that time. Seen in August, 1925, he had a definite Parkinsonian mask, and some rigidity of the right arm. His brother stated that he had altered in character very considerably. After the first washing out he expressed himself as feeling much better. Concentration, which had been much impaired, began to return, the face became less mask-like, and the arm less rigid. In October, 1925, he stated that he was free from symptoms and that mental power had been completely regained; he returned to research work of a very intricate nature.

Case 6.—A woman, aged 32, gave a history of eighteen months' illness, starting with fever, diplopia, and drowsiness. She had the Parkinsonian mask, left ptosis, marked tremor of the right hand and arm, which were useless for all practical purposes. After a washing out she was discharged; a month later she was much improved, the tremor had almost ceased, the grip was good, and her expression was brighter.

In addition to these cases one patient recovered to a great extent, but had a severe relapse six months after discontinuing treatment. Another patient of feeble physique and in a very advanced state made no appreciable progress. Five out-patients, all of whom are improving, are unanimous in ascribing the change to the washing out, and are most emphatic on this point.

We have also had many patients under similar treatment suffering from the cardinal symptoms of encephalitis with the exception of a mask, but the absence of this renders the diagnosis incapable of proof. For the most part they have been less advanced cases, and the improvement after washing out has been considerably more marked than that which has occurred in the majority of patients described above.

We have had little opportunity of treating cases in the acute stage, and none of them has developed a mask.

Acute Cases.

1. A woman, aged 34, was sent to hospital as a case of encephalitis with a four weeks' history of extreme drowsiness and diplopia. She was washed out twice; when seen six months later she said she felt perfectly well, and was bright and cheerful in appearance. She had no tremors, mask, or spasticity of limbs, and vision was normal, but she owned to being more irritable than before her illness.

2. A woman, aged 20, gave a history of three weeks of pyrexia and sleeping "nearly all the time." There were no other symptoms, but she was sent to hospital as a case of encephalitis in the midst of an epidemic. She was discharged ten days later, after a washing out, and is now back at her work, apparently completely cured.

3. A man, aged 35, was admitted with six days' history of unexplained fever, severe insomnia, tremor and spasticity of hands, and feet in position of tetany, fixed expression, and irrational speech. Two days after a washing out the temperature fell to normal, his mind became clearer, and the limbs which had been spastic became looser. The expression returned to his face, and he was able to get up two weeks after admission.

The total number of cases treated has been 64, and of these 45 have had a Parkinsonian mask.

CONCLUSIONS.

1. It is suggested that the infection in encephalitis lethargica is a symbiotic process, that in the first place the nasal mucous membrane is damaged by one of the catarrhal group of organisms, and that subsequently the virus of encephalitis is inhaled, passes through the damaged mucous membrane, and thus enters the tissues, reaching the brain possibly by the perineural lymphatics.

2. In support of this there is a fair amount of evidence that for the transmission of the disease from one individual to another the virus of encephalitis lethargica must fall on mucous membrane previously altered by inflammation of such a character that its power of absorption of fluids in contact with it is greatly increased.

3. The initial damage to the nasal mucous membrane is generally remediable by treatment, and if remedied it would appear that the virus of encephalitis cannot pass into the tissues, and patients become more susceptible to treatment by drugs.

4. Nasal treatment aims, not at curing encephalitis lethargica, but at preventing admission of fresh virus into the tissues.

5. In those cases where actual destruction has occurred in the central nervous system (a system in which regeneration is impossible) the most that can be claimed for washing out the nasal sinuses is that further irreparable damage is hindered, and in many cases appears to be prevented.

6. The Parkinsonian gait and posture is rarely completely removed without the use of remedial exercises.

APPARENTLY COMPLETE RECOVERY FROM ENCEPHALITIS LETHARGICA OF THE BULBAR TYPE.

BY

F. W. KEMP, M.R.C.S., L.R.C.P.,

ASSISTANT MEDICAL OFFICER, EASTERN HOSPITAL, LONDON.

NOTWITHSTANDING the large number of cases on record, knowledge of encephalitis lethargica is too recent to permit neglect of any clinical material which might serve to illustrate points of diagnostic or prognostic importance. The following case, which was of a very severe type, recovered without any special treatment, and will be found to present some interesting features.

A man, aged 33, was admitted to the Eastern Hospital, London, on April 3rd, 1926. There was a history of two days' illness, which was suddenly ushered in by severe headache with nocturnal delirium. Vomiting and constipation were also complained of, and his medical attendant regarded the case as one of influenza. His condition on admission was as follows. Tongue lightly coated; fauces conges[illegible] of mucus in the pharynx; left side of the f[illegible] ntracted, but no strabismus. He could answ[illegible] but cerebration was delayed. No pain was [illegible] had some difficulty in deglutition. The knee-jerk was exaggerated on the right side, and right ankle clonus could be elicited. Babinski's and Kernig's signs were not present. Examination of the heart and lungs revealed nothing abnormal. The bladder was distended, and 38 ounces of urine were drawn off by catheter. The temperature was normal. The symptoms became more marked the next day, with ptosis, inability to swallow, stertorous breathing, and complete unconsciousness. The cerebro-spinal fluid was under slightly raised pressure. The optic discs were pale and sharply defined. Nasal feeding was resorted to. By 10 p.m. the patient appeared to be *in extremis*. Rectal saline with 4 per cent glucose was ordered.

Throughout the night the patient's condition remained so grave that recovery seemed to be out of the question. He began to improve the next day (April 5th); he became partially conscious, and was able to protrude the tongue, though not to speak. There was incontinence of both urine and faeces. The Parkinsonian facies was very obvious, and the arms were crossed on the chest and paralysed, the right completely; temperature 99.8°. Fibrillary twitching in the muscles of both legs and pharyngeal paresis developed later in the day, followed by an epileptiform seizure of ten minutes' duration.

The next day (April 6th), when ankle clonus was elicited on both sides, clonus was sustained for some seconds on the left side after removal of the stimulus. The temperature was 100.6°. Progress was uninterrupted and rapid, till by April 12th all paralyses had passed off. He had apparently made a complete recovery, and was discharged on May 20th.

The diagnosis of the case presented considerable difficulty at the outset. A consulting neurologist, who saw the

patient on April 4th, inclined to the view that tuberculous meningitis might be a probable explanation of the symptoms, though he had in mind the possibility of lethargic encephalitis. In the light of the subsequent history of the case he fully concurred with the ultimate diagnosis. The prognosis in the early stages of the disease was considered to be hopeless by a number of medical men who saw the patient.

As almost every feature which previous observers have regarded as of grave import was present in this case, the patient's complete recovery must be deemed remarkable. The sudden and severe onset indicated an unfavourable prognosis, as H. F. Smith found a mortality rate of 60 per cent. in cases with sudden onset. The severity of the general symptoms was also of unfavourable omen, as, from a study of the official records of the Ministry of Health, Parsons concluded that cases with marked general symptoms were more fatal than those in which the local symptoms were more prominent. Hall states that sudden death is not uncommon in cases, such as the foregoing, where bulbar symptoms were a prominent feature. Edwin Bramwell has emphasized the gravity of the prognosis in cases where previously deepening lethargy was accompanied by such symptoms as a rising temperature, profuse sweating, and incontinence; sweating, however, was not noticed in the case here recorded. Most observers agree that a severe attack is not necessarily followed by residua, and up to the present none have manifested themselves in this case. In view of the frequency with which cases are recorded as illustrative of the beneficial action of some particular remedial measure, it is significant to observe that a case of the gravest type may recover without any special treatment.

I am indebted to Dr. J. Wilkins, medical superintendent of the Eastern Hospital, for permission to publish this note, and to Dr. G. W. Ronaldson for directing my attention to the literature of lethargic encephalitis.

THE EXPERIMENTAL PRODUCTION OF STONE IN THE BLADDER.*

BY

ROBERT McCARRISON, C.I.E., M.D., D.Sc., F.R.C.P.,
LIEUTENANT-COLONEL I.M.S.;
DIRECTOR, DEFICIENCY DISEASES INQUIRY, INDIAN RESEARCH FUND ASSOCIATION, PASTEUR INSTITUTE, COONOOR, SOUTH INDIA

THE EXPERIMENT.

EARLY in 1926 young rats to the number of 120—66 females and 54 males—aged between 60 and 90 days, were fed on a diet consisting of tinned Scotch oatmeal 636 grams, linseed meal 240 grams, tinned cornflour 300 grams, sodium chloride 12 grams, calcium phosphate 12 grams, and distilled water 450 c.cm. The ingredients were mixed together and made into cakes by baking in a slow oven. The animals were given as much of this diet as they cared to eat. Distilled water was provided for drinking purposes. One half of them (33 females and 27 males) were given iodine in the drinking water, in the proportion of 0.1 mg. to the litre; the other half were given no iodine in the drinking water. The presence or absence of iodine in the water made no difference to the results in so far as stone in the bladder was concerned.

During the course of the experiment it was observed that the diet was very faulty: the young rats failed to grow normally, cannibalism was frequent, and the animals suffered from a variety of diseases, of which one was urolithiasis, another a severe anaemia resembling "pernicious anaemia" in the human subject. When the experiment had been in progress for one month 16 rats were killed by chloroform and subjected to *post-mortem* examination; similarly, 16 were killed and examined at fortnightly intervals up to the end of the eighth week. Stone in the bladder was not found in any of them. The experiment was then carried to the death of the remaining 72 animals, the last rat dying on the 157th day. Complete *post-mortem* examination was made in each case immediately after death. The present note deals with those animals found at *post-mortem* examination to have been suffering from stone in the bladder.

The chemical composition of the diet is given in the following table.

Table showing the Composition of the Diet used in the Experiment.

Constituent.	Percentage	
	Expressed on Original Sample.	Expressed on Moisture-free Sample.
Moisture	20.50	—
Mineral matter	5.73	7.20
Ether extractives	10.45	13.14
Crude protein	9.705	12.26
Crude fibre	1.05	1.32
Carbohydrates	52.555	66 08
Total	100.00	100.00
Albuminoids...	9.36	11.77
Insoluble mineral matter	0.37	0.465
Soluble mineral matter	5.36	6.735
Total	5.73	7.20
Soluble silica	0.0363	0.0456
Phosphoric acid (P_2O_5)	1.451	1.82
Iron oxide (Fe_2O_3)	0.046	0.058
Alumina (Al_2O_3)	0.366	0.462
Mangano-manganic oxide (Mn_3O_4)	0.0014	0.00176
Lime (CaO)	1.08	1.38
Magnesia (MgO)	1.05	1.32
Potash (K_2O)	0.21	0.264
Sulphuric acid (SO_3)	0.19	0.23
Chlorine	0.396	0.49
Soda and undetermined (by difference) ...	0.533	0.664
Total	5.36	6.735

The table shows that the protein content of the diet was relatively low; the absence from it of protein of animal origin (milk) was a serious fault. The oatmeal contributed approximately 5.67 per cent. of the total protein, the linseed meal 5.21 per cent., and the cornflour 1.37 per cent. A further fault was deficiency of vitamin A. The sole source of this factor was the oatmeal and the linseed, the amount provided by the cornflour being negligible. All seeds are deficient in vitamin A to a greater or lesser extent; in comparison with others, oats is relatively poor in vitamin A, linseed relatively rich in it. The experimental diet, therefore, though not devoid of vitamin A, did not contain a sufficiency of this factor; the failure of the animals to grow normally and their susceptibility to various infections were due in part to this cause. The diet was not deficient in vitamin B, nor did it appear to be deficient in vitamin E, but it was, no doubt, deficient in vitamin D, although the animals presented no clinical signs of rickets. A further fault in the experimental diet was its richness in phosphates, and in lime, magnesia, and chloride; it contained approximately twice as much phosphorus (P_2O_5), three times as much calcium (CaO), and six times as much magnesium (MgO) as is present in the average well balanced human dietary. To these faults there was possibly added a toxic action of the diet itself on the urinary tract.

* An abstract, published by permission of the Director-General Indian Medical Service, of a paper which will appear in full, with additional illustrations, in an early issue of the *Indian Journal of Medical Research*.

RESULTS OF THE EXPERIMENT.

Of the 72 animals fed on this diet for longer than fifty-six days, 21 were found at *post-mortem* examination to have stone in the bladder—17 females and 4 males; a case incidence of 29 per cent. The incidence of the disease varied in the two sexes, being 40 per cent. in females and 13 per cent. in males. In two other cases in females an intense cystitis, but no stone, was present; in one of these there was some earthy incrustation around the neck of the bladder. Haemorrhage from the bladder was occasionally observed during life. In males protrusion of the penis was a constant symptom in those suffering from stone.

In 18 cases in which stone was found, a greater or lesser degree of cystitis was present; in these the bladder was

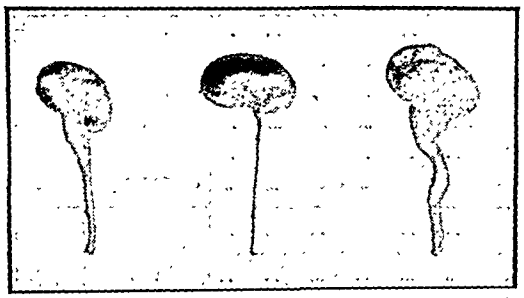

FIG. 1.—Kidneys, with ureters, from two cases of experimentally produced stone in the bladder in rats. The middle kidney (with ureter) is from a healthy control animal.

usually greatly distended and congested. In 3 cases there was no cystitis, showing that the deposition of the phosphatic calculi was not secondary to inflammation of the bladder. In 8 cases the left ureter was much dilated with associated pyonephrosis or hydronephrosis (the fluid was not examined for pyogenic organisms). The photograph (Fig. 1) shows the ureters in two affected animals and that of a control animal for comparison. Earthy deposits, but no formed stones, were present in the kidney in 4 cases. The stones in the bladder were either single or multiple, as many as five being found in one bladder (see Fig. 2); they were of a dirty white colour and their surfaces were rough and jagged. Occasionally formed stones were not found, or if

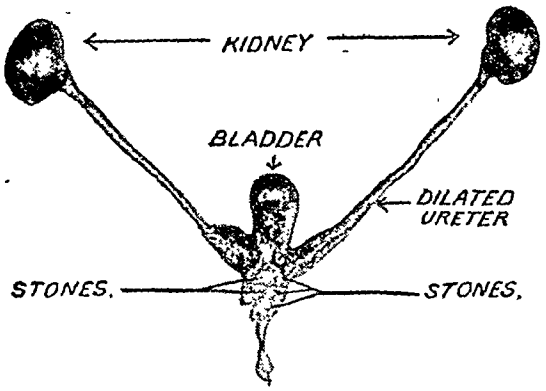

FIG. 2.—Experimental production of stone in the bladder in rats. The diet was the same as that described in the text, except that whole wheat flour was substituted for the oatmeal. Each ureter also held a small stone; there were five in the neck of the bladder.

found were so minute as to be more properly called "gravel." Earthy incrustations around the neck of the bladder were sometimes present. The stone, stones, or gravel varied in weight in individual cases from 17 mg. to 27 mg. in males, and from 8 to 42.6 mg. in females. The largest single stone weighed 35 mg.; a stone of proportionate size in man would have weighed about one pound. Chemical examination showed the calculi to consist mainly of earthy phosphates (calcium and magnesium) along with traces of calcium oxalate. Stone was found only in animals which died between the 84th and the 157th day of experiment; the diet did not appear to cause the disease until after fifty-six days of its use.

During the 157 days this experiment lasted 340 *post-mortem* examinations were made in rats which had been fed in various other ways. In none of these was stone in the bladder present. The stock diet in use in my laboratory does not give rise to calculus in rats; it consists of whole wheat chapatties, milk, butter, sprouted pulses, green vegetables, raw tubers, fresh meat in small quantities once a week, and water. Nor do synthetic diets deficient in vitamin B, but complete in other respects, cause stone in the bladder in rats; nor diets whose sole fault is deficiency of suitable protein or of suitable salts; nor synthetic diets whose sole source of vitamin A is 8 per cent. of pure Lucca oil. It seems, therefore, that the diet used in the present experiment was productive of calculus because of the peculiar combination of its faults—deficiency of vitamin A, absence of animal protein, richness in earthy phosphates, with possibly a toxic action of the ill-balanced diet itself on the urinary tract. This tentative interpretation of the results observed is to be considered in connexion with the recently reported observation of Fujimaki (1926) that stone in the bladder and kidney can be produced in rats by feeding them for long periods on synthetic diets deficient in vitamin A. The experimental production of stone in the bladder by means of an ill-balanced diet composed of foods in common use by man would appear to confirm and to extend the observation of Fujimaki, although it raises other considerations which require further investigation for their elucidation.

CONCLUSIONS.

1. Stone in the bladder has been produced in rats by means of an ill-balanced diet composed of foods commonly used by man. The stones were of the phosphatic variety.

2. The main faults of this diet were: (*a*) absence of protein of animal origin; (*b*) deficiency of vitamin A; and (*c*) excess of earthy phosphates. To these faults there may possibly have been added a toxic action of the diet itself on the urinary tract.

ACTINOMYCOSIS IN THE BRAIN OF A CHILD.

BY
JOHN D'EWART, M.B.LOND.,
MEDICAL SUPERINTENDENT, BOOTH HALL INFIRMARY FOR CHILDREN, MANCHESTER;
AND
GEORGE D. DAWSON, M.D.VICT., D.P.H.,
PATHOLOGIST TO THE MANCHESTER UNION HOSPITALS.

ACTINOMYCOSIS is sufficiently rare to warrant a record of the following case in a child, aged 11, in which the brain was affected.

Actinomycosis, first reported by Bollinger in bovines in 1877,[1] and in man by Israel in 1878,[2] and by Porfick in 1879, is rather rare, and this appears to be the only instance of its occurrence in the brain of a child. Records of English cases appear to be limited to that described very fully by Delépine in 1889[3]; the patient was a decorator, 65 years of age.

Moersch in 1922[4] reported from the Mayo Clinic seven cases affecting the brain, all of which were secondary infections, the youngest being aged 20 and the oldest 41.

In the United States Sanford and Voelker collected (1925) 670 cases.[5] Among 574 in which the ages are known, there were 14 under 10, and 89 between 10 and 20. Of 588 cases where the location was known, there were only 9 in which the brain was affected: of these the youngest was 24 years of age, and the oldest 63.

A boy, born on January 15th, 1915, was admitted to the Booth Hall Infirmary for Children, Manchester, on September 27th, 1926. The history was that he had been quite well until March, 1925. He then complained of pain in the right side, and had twitching of the right arm and leg, of which he also lost the use. Later on he complained of headache and vomiting, and was admitted to the medical side of the Manchester Royal Infirmary, being transferred to the surgical side on July 26th, 1926, as a case of left cerebral tumour with increased intracranial tension. He then had left-sided headache, and the right arm showed flaccid paralysis. Vomiting, unaccompanied by nausea, was present. Sensation was unimpaired, but there was bilateral optic neuritis.

Operation.—On July 28th Mr. C. Roberts, F.R.C.S., performed left parietal decompression; considerable bulging of the brain was noticed when the dura was opened, but no localized tumour could be detected, and when the wound healed there was still bulging.

After-History.—On admission to Booth Hall Infirmary there was a large swelling over the left parietal area—4 inches by 2 inches; the skin in one part was broken down, and there was a purulent discharge. The right foot was in the position of talipes equino-varus. The wrists were hyperflexed, but could be extended voluntarily. The oculist reported slight blurring only of the disc edges; the vessels were not engorged. The Wassermann test was negative, and general examination, including x-ray examination of the thorax, did not afford any evidence indicative of tuberculosis. The diagnosis was cerebral tumour, not syphilitic, and probably not tuberculous. The child remained comfortable, and gained 2 lb. in weight until the second week in November, when he was reported as not so well; there was oozing of cerebro-spinal fluid and oedema of feet and scrotum. Albumin, half a gram to the litre, was present in the urine. Diarrhoea commenced a week later, and vomiting started the day following, death ensuing in a couple of days (November 24th, 1926).

Post-mortem Examination.—This was performed on the following day. Dr. Dawson reported as follows: "Beneath the fluctuant swelling on the left side of the head was an abscess the size of a Tangerine orange in the brain substance, containing greenish pus. Pus of the same kind was free at the base of the brain. The liver and spleen, the latter fixed by dense fibrous adhesions to the stomach, contained very extensive suppurating areas with a honeycomb appearance, with pus of the same greenish colour. The base of each lung was similarly affected, but to a small extent only. No other organs were found to be affected. Microscopically, sections of isolated nodules from the liver and spleen showed granulomatous lesions, including one or more typical actinomycotic colonies.

"Diagnosis: Actinomycosis, with extensive metastasis. The site of the original infection is not clear, but may have been gastric."

Thorough inquiry into the history shows that the patient had nothing to do with horses or grain, but regularly carried straw from banana crates. This is the only suggested means of infection.

Thanks are due to the librarians of the Manchester Medical Society and of the British Medical Association for their assistance in an extensive search of the literature, to Mr. Charles Roberts for the use of his notes, and to others for the assistance they have given.

PERNICIOUS ANAEMIA IN ELDERLY PEOPLE.

BY

W. L. TEMPLETON, M.D.,

LONDON, N.

PERNICIOUS ANAEMIA is regarded generally as a disease of middle and later life, and it does not seem to be as generally recognized that it may occur in persons of 70 years and over.

Cabot[1] makes the striking statement that pernicious anaemia is a disease of elderly people, its incidence being not far different from that of cancer; and Eason,[2] working on the figures of the Edinburgh hospitals, concludes that senility is a much more important etiological factor in the production of the disease than has been hitherto recognized. He finds, too, that the rate of incidence in the sexes varies with age. Under 50 the rate of incidence is higher in females than in males; over 50 the reverse is true. Ward[3] could find in the literature four other cases besides his own in which the disease had been recognized in patients over 70 years (70, 73, 76, and 80), and his own patient was 85 when she died.

The following notes refer to two women over 70 who both died of the disease. In one (Mrs. B.) the disease undoubtedly began after she had passed her 75th birthday, and in the other (Mrs. M.) probably at the age of 67 or thereabouts. The fact that the disease may have commenced at a much earlier age and undergone long remission has not been forgotten, but a careful inquiry into the history does not reveal any evidence to support this view, and both patients were under the supervision of the same medical attendant for many years.

CASE I.

Mrs. B., aged 75, was operated on for double hernia when over 70 years of age. She was very feeble for several years before the symptoms and signs of severe anaemia appeared, and was thought to be suffering from general arterio-sclerosis, but no focal lesions were observed and her blood pressure was below normal. She had a good appetite, slept well, and complained of little until three or four months before her death, when she showed the typical lemon tint of the skin, developed complete anorexia and obstinate constipation, and died from progressive weakness. A blood examination, which was repeated, showed:

Red cells	850,000 per c.mm.
Haemoglobin	30 per cent.
Colour index	1.7
Leucocytes	2,000 per c.mm.
Differential count:	
Polymorphs	30 per cent.
Small lymphocytes	69 ,,
Normoblasts	1 ,,

There was marked poikilocytosis and anisocytosis.

CASE II.

Mrs. M., aged 70, was always pale but had no severe illness before three years ago, when some grave form of anaemia was suspected. No blood examination was made, and the patient was able to go about her household duties fairly well until about six months before her death, when she complained of sensory changes in the fingers and toes, described as tingling, burning, and numbness. Later loss of temperature sense was noted, but at no time was there evidence of involvement of one big toe. She had tract except for involuntary twitching of one side of the face, for a peculiar interrupted form of speech, cog-wheel in type, for which no explanation could be found by the laryngologist or neurologist who examined her. A blood examination showed the following:

Red cells	1,500,000 per c.mm.
Haemoglobin	28 per cent.
Colour index	1+
Leucocytes	5,000 per c.mm.
Differential count:	
Polymorphs	32 per cent.
Small lymphocytes	64 ,,

Poikilocytosis and anisocytosis were present.

Three weeks later the red cells fell to 900,000 per c.mm., whereas the haemoglobin was if anything higher, in the region of 30 per cent., giving a colour index of 1.6.

ANEURYSM OF POSTERIOR TIBIAL ARTERY CAUSED BY FRACTURE OF THE TIBIA AND FIBULA.

BY

MANFRED MORRIS, M.D., CH.B.,

MAJOR R.A.M.C.; SPECIALIST IN SURGERY TO THE CENTRAL PROVINCES DISTRICT, INDIA.

CASES of aneurysm of the posterior tibial artery of traumatic origin are of sufficient rarity to justify the publication of the following notes.

A native cavalry soldier, aged 26, was admitted to hospital, having fallen and broken his left leg, both bones being fractured at about the junction of the middle and lower thirds. Radiological examination showed no points of special interest, the fracture being transverse with little displacement and separation. The limb was treated by fixation on a back splint, with footpiece and side splints. I was asked to see the man four months after the accident as there were no signs of union. I found him to be a healthy man with no venereal history; the limb was considerably wasted. Radiological examination showed the fragments to be in good position. There were no signs of callus or reaction at the ends of the bones. I recommended that the limb be re-splinted, and the patient given a liberal diet, a course of tonics, and potassium iodide. His Wassermann reaction (seven weeks after the accident) was negative on two separate dates. Three weeks later (seven weeks after the attempt at union. I now found a pulsating expansile swelling in the calf opposite the point of fracture; it was the size of a hen's egg and in the line of the posterior tibial vessels. A loud blowing systolic bruit could be heard over the tumour; this disappeared on compressing the main vessel above the mass. The pulse at the ankle could not be felt, but the circulation in the foot appeared to be normal. There was some irregularity and a very accentuated first sound. I wondered if these physical signs were the so-called "tumultuous action of the heart" described by Makins in cases of consisting of marked disordered action of the heart, aneurysm of peripheral vessels. A diagnosis of arterio-venous aneurysm was obvious, and, as the swelling at the end of a week appeared to be rapidly enlarging, I decided to operate.

Operation.

The operation consisted in applying a tourniquet and excising the sac, tying the vessels above and below it. Posteriorly the sac was covered by fascia and skin only, any muscle tissue having entirely disappeared; the fascia was stretched and thinned out over it. Anteriorly the sac was very adherent to periosteum, and had hollowed out the tibia, forming a smooth cup-shaped depression

through which ran the fracture. The sac, on being opened and the clot turned out, showed the openings of seven vessels into its wall. I had at first contemplated plating the fracture as a second stage of the operation, but, owing to the fact that the patient did not take the anaesthetic well, and that the dissection took longer and was more difficult than I had expected, I decided to abandon plating until a later date. The ends of the fragments were curetted. The cavity made by excising the sac having been obliterated by deep catgut sutures, the wound was closed, and the limb was then put back on the original type of splint. The wound healed by first intention, and the circulation in the limb appeared normal. Six weeks later there was good union. The patient was discharged from hospital, and is now doing his duty. The excitable heart condition improved and disappeared.

Fractures of the tibia and fibula in this position, due to indirect violence, are so common, and injuries to the vessels so rare, that at first I wondered if there might not have been some direct violence (kick) damaging the vessels. The violence was, however, of a twisting nature. The foot caught against an irregularity in the ground, and the man, half turning round, fell down. He was emphatic that there had been no kick or direct violence.

Aneurysms of the posterior tibial artery are rare. Crisp,[1] in his table of 500 aneurysms, reports only two cases of aneurysm of the posterior tibial. The India catalogue of the library of the Surgeon-General, U.S.A., gives a list of eighty cases of aneurysm of peripheral vessels, of which only one—a case of diffuse aneurysm of the anterior tibial artery—was due to fracture.[2]

Treatment by operation in this case was most successful. Digital or instrumental pressure was not attempted in view of the complicating fracture and the rapidly increasing size of the tumour. In this case there can be no doubt that the posterior tibial vessels received an injury at the time the fracture was incurred. It is a remarkable fact that the vessels escape as often as they do. The failure to unite was certainly caused and aggravated by the presence of the aneurysm; the surrounding tissues were very dense and fibrous, and showed considerable peripheral connective tissue hyperplasia, which interfered with the nutrition and bone-forming units at the ends of the fragments. There were no signs of general vascular disease. The man was young, healthy, and, as far as shown by the Wassermann test, free from syphilitic taint.

LOCAL ANAESTHESIA IN SUBMUCOUS RESECTION OF THE NASAL SEPTUM.

SUBMUCOUS resection of the septum nasi gives good results in suitable cases, but it is not an easy operation. A high authority has, indeed, stated that in any case in which it proves easy it was not needed, and the difficulties natural to it are greatly increased by the use of general anaesthesia, however skilfully administered.

After a long and mainly disappointing experience of many varieties of local anaesthesia I have found a method which permits of the most extensive resection without pain, haemorrhage, or the need for hurry. It is as follows.

One hour before the time fixed for operation the patient receives half a grain of morphine by hypodermic injection. When upon the table he is assured that no pain will be inflicted. The nasal mucosa is then very gently but very thoroughly gone over with a cotton mop repeatedly dipped in a solution of adrenaline. This is massaged into every part of the nasal cavities that can be reached, half a drachm of adrenaline being used. Five minutes at least are devoted to the application, after which anaesthesia is induced by the surface application of cocaine. Three grains of cocaine hydrochloride crystals are measured into a porcelain capsule, and a cotton-tip, wet with adrenaline solution, is loaded with the solid cocaine; the nasal cavities are then massaged with it until the whole of the cocaine has been applied. It is important to leave no area of the nasal mucosa untreated. The operation can then be undertaken.

The completeness of the anaesthesia is unbelievable until one has had experience of it, and the absence of haemorrhage eliminates the chief difficulty of the operation. During the past few months I have employed the method in thirty-eight cases, and find it incomparably superior to any means of inducing local anaesthesia by injection. The entire absence of toxic symptoms may be attributed to the thorough application of adrenaline, which is an indispensable preliminary. I owe my knowledge of the method to the kindness of Dr. Dan McKenzie, who demonstrated it to me last year at the Central London Throat and Ear Hospital.

HENOCH'S PURPURA IN AN ADULT SIMULATING "ACUTE ABDOMEN."

THE report of a case of Henoch's purpura in an adult by Dr. Alex. G. MacGillivray, in the JOURNAL of February 12th (p. 279), prompts me to record the following case.

A single woman, aged 19, was admitted to Lincoln County Hospital on November 23rd, 1926, complaining of pain of two weeks' duration in the lower abdomen, vomiting, and diarrhoea. The diarrhoea ceased in a week, but intermittent vomiting and pain continued up to the day of admission. There was no history of epistaxis or headache, etc.

The patient looked extremely ill; the tongue was furred and the breath foul. The temperature was 102°, the pulse 80, and respirations 24. The chest was normal. The abdomen was not distended, but did not move well, and there was tenderness and rigidity in the lower half, more on the right side than the left. On rectal examination no mass could be felt, but there was tenderness. The urine contained a slight trace of albumin.

The low pulse rate was difficult to interpret, but in view of the signs of peritonitis it was decided to operate. The abdomen was opened by a median incision, and the pelvis was found to contain several ounces of blood-stained fluid. The ovaries, tubes, and uterus were normal, as were the caecum, appendix, and ileum. The greater part of the jejunum was found to be swollen and intensely hyperaemic, with patchy effusions of blood. No ulceration was discovered, and there were no signs of strangulation, intussusception, or volvulus. The serous coat of the jejunum and ileum were normal, and Peyer's patches were not enlarged. The blood-stained fluid was mopped out, and the abdomen closed, Henoch's purpura being diagnosed. On the next day the temperature fell to normal and the patient was much better. There was some black vomit on November 25th, but after that the patient took food well.

On December 4th a typical purpuric rash appeared on her arms and legs. This soon disappeared and the patient made an uneventful recovery.

This case illustrates the well known fact that abdominal symptoms may appear before the purpuric rash, that intestinal obstruction or appendicitis may be simulated, and that the effusion of blood may produce peritonitis and further complicate the diagnosis. The normal pulse rate was also a feature of Dr. MacGillivray's case.

I am indebted to Dr. Watkins, surgeon to Lincoln County Hospital, for permission to publish this case.

Edinburgh. JOHN A. HADLEY, M.B., B.S.

TREATMENT OF INFLUENZA.

DURING the great influenza epidemic in 1918 I found the following treatment useful in cases with pyrexia or epistaxis and pulmonary complications.

Amm. chloridi	3 jss
Liq. amm. acetatis	3 vj
Tr. euonymi	3 ij
Tr. nucis vomicae	3 jss
Ess. pepsinae	q.s. for 3 iv

One teaspoonful in a wineglass of water every two hours until better, then every four hours until well.

This treatment is based upon the experience of 1,972 cases, most of them in the crowded districts of Boston. There was no available nursing and the hospitals were overcrowded. Most of our physicians were at the front, and of those at home many were ill themselves.

In the gastro-intestinal form with anorexia and emesis the addition of one ounce of milk of bismuth was effective. The ensuing complications of bronchiolitis or lobular pneumonia responded equally well. The addition of strophanthus in long cases marked by cardiac failure was necessary.

Boston, U.S.A. I. EUGENE REID, M.B., C.M.Ed.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.

A meeting of the South Wales and Monmouthshire Branch at University College, Cardiff, on March 31st, the President, Dr. R. PRICHARD, in the chair, Dr. HERBERT T. EVANS read a paper on paroxysmal tachycardia.

Dr. Evans said that though paroxysmal tachycardia had been recognized so far back as 1867, it was only clearly defined about twenty years ago, mainly in consequence of the electro-cardiographic work of Lewis. In this condition the auricles and ventricles contracted in their usual sequence at a rate of 110 to 200 per minute, which contrasted with the auricular rate of over 300 per minute encountered in auricular flutter, the ventricular rate in this condition being 240 to 250. Dr. Evans described the normal cardiac cycle, and said that in paroxysmal tachycardia the stimulus did not start in the sino-auricular node, but in a new spot usually situated in the auricle or auriculo-ventricular node. The new rhythm thus initiated was characterized by its sudden onset and cessation; its regularity; and the absence of change of rate after exercise, alteration of posture, emotional manifestations, and the use of drugs such as atrophine and digitalis. The duration of the tachycardia was usually short; it was accompanied generally by palpitation, shortness of breath on exertion, and nervous excitability or anxiety. Precordial pains had been noted, and gastric symptoms were common. Prolongation of the paroxysms was liable to produce acute cardiac failure, but sudden death was rare; nevertheless, the prognosis should be guarded in the case of patients known to have other forms of heart disease, and when the lesion could be associated with paroxysmal tachycardia, attacks were frequent and severe. No constant heart which often started in an apparently sound heart; children and young adults had been reported to grow out of this condition. The treatment was symptomatic, and morphine and chloral should be safely given.

The paper was illustrated by several electro-cardiograms.

Lupus Vulgaris.

Dr. J. BEATTY showed twelve cases of lupus and described the treatment adopted in each. He said that out of eighty patients treated by him during the last four years, two had developed epithelioma and one tuberculous abscesses. In another case pyrogallic ointment had been effective, though the condition had lasted for seven years, and large areas of the thigh, arm, and face were affected. After application of the ointment for four years the disease was replaced by large, white, pitted, and supple scars. This treatment was not suitable for general use in an out-patient department because it was slow and caused much pain. Little benefit had followed the use of x rays, but salicylic and creosote plaster was valuable when patients could only attend at long intervals. The prolonged use of ultra-violet rays had been helpful, but the treatment found most serviceable had been the application of alkaline phenol, followed by a hypertonic dressing.

Syphilitic Ulceration of Trachea.

Dr. D. P. PATERSON showed a specimen of syphilitic ulceration of the trachea in a West African seaman, aged 29. Death had been due to the large amount of watery mucus in the lower part of the trachea and large bronchi. The illness was said to have lasted six weeks, the chief symptom being noisy breathing during sleep; there was no stridor when the patient was awake, and the voice was unaffected. The larynx was normal, except for injection of the whole of the subglottic area. There was no pyrexia and the Wassermann reaction was negative. At necropsy the posterior wall of the trachea was found to be ulcerated just below the glottis; the bronchi were filled with watery secretions; parts of the lungs were oedematous; the mediastinal glands were enlarged; gummata were present in the liver; and there was fibrous thickening of the testes.

Paroxysmal Tachycardia.

Mr. Lambert Rogers read a paper on the diagnosis and treatment of various types of goitre. He said that valuable diagnostic aid was provided by determining the basal metabolic rate, and by the test devised by Emil Goetsch of Boston, which was based on the fact that in thyrotoxicosis the sympathetic nervous system was hypersensitive to adrenaline. He divided thyroid enlargement into the diffuse and nodular types. In the first were comprised the non-toxic physiological enlargement of the gland at puberty, the endemic parenchymatous non-toxic variety, and exophthalmic goitre. Nodular goitres might be solid or cystic, and single or multiple; iodine should never be given to patients with nodular goitre. Malignant disease scarcely ever commenced in a previously healthy thyroid gland. Mr. Lambert Rogers discussed the indications for the surgical treatment of goitre and said that in competent hands the mortality was now lower than that of abdominal surgery. Before an operation an x-ray photograph should be taken of the neck to define the position and condition of the tracheal shadow. Other essentials were an electro-cardiogram, a daily record of the larynx, a skiagram of the thorax to show the shape and size of the solid shadow, a report of the Goetsch test, estimation of the basal metabolic index, and a complete blood analysis.

Diagnosis and Treatment of Goitre.

Reports of Societies.

VENESECTION.

At a general meeting of Fellows of the Royal Society of Medicine, on April 7th, with Sir STCLAIR THOMSON in the chair, a discussion on "blood-letting" was opened by Mr. WALTER G. SPENCER.

Mr. Spencer ascribed the disuse of venesection, especially in private practice, mainly to the existence of certain prejudices; he traced the historical origin of the practice and of the feeling against it. The theories concerning the efficacy of the loss of blood had a prehistoric origin; the relief afforded by haemorrhage from the nose or piles was frequently quoted, and such natural occurrences probably suggested the undertaking of venesection as so well established as looked upon the use of venesection as so well established as to need only casual references. Asclepiades and Themison recognized the secondary benefits afforded by bleeding. Celsus advocated moderation, and Galen, while stating the average amount of blood usually allowed to flow, boasted of extreme quantities which had been let out. The Arabians extracted blood from a spot as far away as possible from the supposed seat of the disease, advocating the theory of "revulsion" as against "diversion"—that is, the withdrawal of blood from as near the seat of disease as possible. These two theories gave rise to a violent controversy, the Paris school following the Arabian physicians, while the Royal College of Physicians in London held to "diversion." The custom of periodically bleeding healthy persons was a mediaeval one and, incidentally, favoured the rise of the Guild of Barbers. However, certain influential opinions began to be expressed against the traditional ideas on venesection, and John Hunter was one of the first to break with tradition. Marshall Hall, while still in Edinburgh, wrote on some of the dangers of repeated bloodletting, and ten years later, in 1844, Copland's *Medical Directory* omitted all mention of venesection. Hughes Bennett compared cases of pneumonia treated in hospitals in this country by blood-letting and by diet only, with results very much in favour of the latter method. The capital indication for venesection, proceeded Mr. Spencer, was impairment of the pulmonary circulation, and he quoted early experiments on animals with regard to asphyxiation and blood-letting. Sydenham had observed that venesection served instead of a tracheotomy in some cases. In asphyxiation experiments the sudden fall in pulmonary blood pressure produced by venesection caused reflex stimulation of the respiratory centres, leading to better oxygenation of the blood. The speaker next dealt with certain states of grave urgency threatening death

from impairment of the pulmonary circulation in which venesection saved life. Dealing first with pulmonary and cardiac affections he quoted from publications by Henry Sutton and Pye-Smith, and lectures by de Havilland Hall and Hale-White. The effect of venesection on the over-distended heart had in very recent times been observed directly on the x-ray screen by B. Gordon. Cases had been recorded in which air embolism occurring during the induction of an artificial pneumothorax had been prevented from causing death by immediate venesection. Children suffering from scarlatinal nephritis with threatening uraemic coma were greatly benefited by venesection. In young children with the so-called "suffocative catarrh" it was sometimes difficult to open a vein, and cutting across the radial artery to secure the rapid loss of about 100 c.cm. of blood was said to be beneficial. Mr. Spencer then gave details of cases of apoplectiform seizures, status epilepticus, and heat-stroke all treated with great benefit by venesection. He pointed out the distinction between what could be achieved at an organized hospital and the venesection which was capable of immediate application in the absence of other remedies. In cases of asphyxiation by non-irritant gases—carbon monoxide for example—venesection would serve to start natural respiration when artificial respiration, including the administration of oxygen, had failed. Venesection was also of great value in irritant gas poisoning, Schafer having recorded that free blood-letting was the only remedy producing an immediate beneficial effect in dogs poisoned by chlorine gas. Acute poisoning—for example, by alcohol, carbolic acid, mushrooms, etc.—had frequently been treated successfully by blood-letting. Certain chronic affections were also benefited. The headache from high blood pressure and the pain of an aneurysm could be relieved by bleeding, and polycythemia caused by over-production of red blood corpuscles was greatly improved by venesection. Chlorosis had also been treated by blood-letting, especially in Germany.

Dr. HERBERT FRENCH dealt with the use of venesection for certain chronic conditions. The first of these was rare: polycythaemia with splenomegaly. This condition was treated in various ways, but nothing benefited these patients as much as venesection, and no case failed to respond. The second chronic condition was much commoner, but difficult to define. It was closely related to "raised blood pressure," although a rise in blood pressure was not an essential part of the clinical features. Bleeding gave relief, not by lowering the blood pressure, for this might remain at the same level; but the procedure was definitely beneficial nevertheless as gauged by the patient's own feelings. The age of the patients in this group was about 45 to 55; they were usually busy, overworked, and of the intellectual type, with too little exercise, who had always been very energetic in youth. Such a patient complained of vague symptoms, such as giddiness, and that his brain was not working so well. On examination it was usually found that his heart was not working so well either. After bleeding, such patients felt much better, could resume their activities, and they frequently returned to be bled again and again. In women a similar state of affairs was associated with the menopause, and a patient of this type complained of a feeling of increased pressure in the head. Such women all emphatically benefited from venesection, and this should be done much more frequently. Dr. French then gave his views as to why bleeding helped such people. He admitted that there was no satisfactory scientific explanation. Physiologists taught that venesection was useless, since the fluid element of the blood was almost immediately replaced from the tissues, and the other constituents were more gradually replaced in the course of about a fortnight. The speaker thought that in these individuals he had been describing blood destruction was delayed, and bleeding led to the removal of a certain amount of stale blood, which was replaced by fresh blood, and the patient was to a certain extent rejuvenated. He believed that in the past blood-letting had not been sufficiently employed because of the mess it made. He demonstrated a method by use of a special cone-shaped needle and bottle, which enabled a pint of blood to be removed in about five minutes.

Dr. R. FORTESCUE FOX said that in his younger days he had been much impressed with the effect of venesection in certain acute conditions. The pulse almost always became slower and fuller, and the circulation became tranquillized. Later on he (the speaker) became attached to certain water health resorts, where he met frequent "candidates for illness," middle-aged persons on the verge of breakdown, with considerable disturbance of the circulation. He quoted one such case in a woman, aged 70, stout and plethoric, who had a cerebral haemorrhage and became comatose, but recovered after immediate venesection. Cases of apoplexy at spas appeared to be common, and Dr. Fox thought that ingestion of water in certain cases might lead to a dangerous increase in the amount of fluid in circulation. He dealt more fully with the use of venesection in hyperpiesia, mentioning the two well known types—the one well fed and florid, and the other pale and anxious. He thought that hypertensive disturbances were common at certain periods—the menopausal time in woman and a corresponding period in man—and he considered that the essential factor in the production of high blood pressure in these cases was, not structural disease of the arteries, but some disordered nervous mechanism. Dr. Fox then described in detail certain cases of high blood pressure where bleeding had been performed at the onset of certain "pressure waves" when definite rise in blood pressure occurred. The various classical symptoms of these hyperpieties were, in his opinion, better indications for bleeding than the actual height of pressure present. He added that death from cerebral haemorrhage was becoming increasingly more common, especially in brain-workers and public men, and he thought it could be prevented in many instances by timely venesection. In treatment of high blood pressure cases it was necessary to follow the venesection with a period of other depletive measures, such as starvation, rest, and purgation. In conclusion, Dr. Fox protested against the teaching that venesection did not affect blood pressure. This was founded on physiological experiments in the healthy, and there was much clinical evidence to show that results were altogether different in diseased persons.

Sir WILLIAM HALE-WHITE began by stating that if the discussion had taken place eighty to ninety years previously several hundred people would have been bled in the afternoon in London, since every person who looked after his health in those days was bled every spring and autumn. In 1840 a doctor was charged with malpraxis for failing to bleed a patient with pneumonia, but there had been a great change, especially since the great blood-letting controversy of 1850-60. Before that date venesection appeared to be carried out for no other reason than that it was fashionable. Dealing next with the modern indications for blood-letting, the speaker said that the cases above all others which benefited were those in which the right side of the heart was overfilled. The guide should be, "Is the patient livid?" It was found that after venesection in such cases digitalis acted better. In pneumonia bleeding was indicated only if the cases were livid. In apoplexy bleeding should only be performed if there was respiratory embarrassment, and the same remarks applied to status epilepticus and sunstroke. In uraemia not much permanent good resulted unless the patient was livid from convulsions. Bleeding relieved the pain of aneurysms and was beneficial in polycythaemia. Lastly, the speaker mentioned two practical points. The patient should always be bled sitting up, so that he could be placed flat if fainting occurred. Secondly, care must be exercised in bleeding the young or very old patients.

Sir JAMES DUNDAS-GRANT described certain cases where venesection had been very useful. A case of severe uraemic coma in a girl after scarlet fever was cured completely by a timely venesection. A boy who had been resuscitated after drowning was found with a purple face and great respiratory embarrassment. He recovered completely after venesection. Another case of severe puerperal eclampsia was also benefited.

Sir WILLIAM WILLCOX said he had early been interested in the subject of blood-letting, since he had been a disciple and pupil of an ardent believer in the procedure, Dr. David Lees. He considered that it was indicated in five classes of cases: (1) Those in which the right side of the heart was dilated. (2) Convulsions, especially status epilepticus, which it would almost always stop. In uraemia

it was of most use in temporarily acute conditions with convulsions, such as in eclampsia. (3) Heat-stroke. In 1917 he had seen many cases of this condition, and venesection alone did most good in cases with cyanosis and convulsions. (4) Polycythaemia, where venesection was a very important form of treatment. (5) Certain medico-legal cases, such as forms of violent asphyxia from drowning or hanging. In high blood pressure cases with definite "pressure waves" a timely venesection was most beneficial. Dr. H. Letheby Tidy summed up the conditions in which venesection should not be employed as chronic anaemias and low blood pressure, especially in elderly people. The indications upon which most people appeared to be agreed were polycythaemia and certain cases of high blood pressure among the chronic group and acute conditions associated with lividity and right heart dilatation. In uraemia there appeared to be two groups: acute cases in which venesection did good, and chronic cases in which it should be not performed. It was also agreed that it was beneficial in sunstroke.

ORAL SIGNS OF GENERAL DISEASE IN CHILDREN.

The Sections of Odontology and of Disease in Children of the Royal Society of Medicine combined on April 6th for a discussion on "Oral manifestations of general disease in children." The chair was taken by Mr. J. B. Parfitt, president of the Section of Odontology.

Mr. A. T. Pitts, dealing first with osteomyelitis of the maxilla in infants, asked what was the nature of this condition. Was it a true osteomyelitis or an antral infection? As the maxilla in infants was a thin shell of bone containing the developing teeth, the tooth crypts soon became infected, and such cases often came within the scope of dental surgery. Treatment should be cautious and limited. Such cases of tuberculosis of the jaw as he had seen had been in the mandible. Did the condition occur in the maxilla, and was it always secondary to tuberculosis elsewhere? Could it occur in a clean mouth, or was it grafted on an existing dental infection? With regard to localized suppuration of the jaws of non-dental origin, although the teeth might be free from caries and appear healthy, a dental cause could not be excluded without a radiograph in addition to clinical examination. Necrosis following scarlet fever, once common, now appeared to be rare. Did this imply that the cause was a lack of oral hygiene which predisposed to infection, and that its present rarity was due to greater attention to hygiene of the mouth as part of the treatment of all illness? Speaking of the teeth in congenital syphilis, he pointed out two features of Hutchinsonian teeth: (1) alteration in architecture so that the sides converged towards the cutting edge, whereas in normal incisors the sides diverged from the gum margin to the cutting edge; (2) an area of badly formed enamel on the cutting edge or an actual deficiency of enamel, leading to a notch. He had never seen Hutchinsonian incisors in deciduous dentition. He believed Hutchinsonian teeth absolutely specific, and his experience confirmed Hutchinson's statement that when perforation of palate occurred the teeth were not affected. He also dealt with some anomalies of eruption and development, and asked whether there was any evidence of the teeth being affected in cases of precocity. In one case which he had seen, in a child of 4 with marked precocity, the dentition was several years in advance of her age. Finally, Mr. Pitts touched on oral manifestations due to vitamin deficiency, as in scurvy and rickets, and asked whether there was any support for the view that follicular stomatitis in children might be due to lack of water-soluble B.

Dr. Robert Hutchison, opening the discussion from the medical side, said that affections of the jaw in general disease were more surgical than medical. General hypoplasia of the skeleton, however, such as occurred in some forms of infantilism, affected the jaws as well as the bones. It was tempting to speculate in this connexion as to the part played by endocrine disturbances. Over-action of the anterior lobe of the pituitary, for instance, caused an overgrowth of the lower jaw in acromegaly, and it was possible that pituitary deficiency might result in under-development of the jaw during the period of growth. In cases of dyspituitarism such an under-development did not appear to occur. There was even less reason to believe that a deficiency of vitamin B could interfere with the development of the jaw. Rickets possibly acted in this way, though he thought it did so to a less degree than might be supposed. The teeth seemed to be more affected than the jaw by general diseases. Their appearance in rickets was delayed. Possibly the teeth were a better index to the real age of the patient than ossification of the epiphyses. In a case of precocious puberty at the age of 3, though the skeletal development was that of a child of 12, he found the milk teeth still present. The influence of general disease on the calcification of the teeth was well seen in rickets, and the observations of Mrs. Mellanby pointed to a deficiency of vitamin A as the cause. The effect of inherited syphilis on teeth was also well recognized. Anything which impaired the general health also might interfere with the laying down of enamel, and a groove more or less broad, or a succession of grooves, with healthy enamel between, might mark attacks of grave illness at that level of enamel formation. Variations in the reaction of the saliva in consequence of affections of the general health might possibly affect the enamel, though little attention had been paid to this subject. Indeed, the whole question of the relation between departures from good general health and a predisposition to dental caries was very obscure. Apart from alterations in its reaction, an increased viscidity of the saliva, the result of a disproportionate "sympathetic" secretion, might be expected to favour caries by interfering with the washing away of food particles. Such an increased viscidity was apt to occur in nervous children. The cause of grinding of the teeth was obscure; it might be merely a bad habit, but it was also met with in many mentally defective children, and in those who suffered from dyspepsia and perhaps from worms. Staining of the teeth was a rare and curious phenomenon, met with when there was circulation of a pigment in the blood whilst the teeth were developing. "Pink" teeth were met with in cases of congenital haematoporphyrinuria, and "green" teeth in jaundice. The gums, being highly vascular structures, usually became affected in diseases of the "haemorrhagic" class, such as scurvy, the lymphatic leukaemias, and purpura. It was possible, even probable, that impairment of general health might, by lowering resistance, favour the occurrence of gingivitis and pyorrhoea, but on this point, as on the influence of the common health on the production of caries, there was no very definite information. Hypertrophy of the tongue was met with in cretinism, and to some extent in mongolism, and in the latter condition fissuring of the organ became pronounced as the child grew. Affections of the mucous membrane of the mouth were, in the speaker's view, for the most part purely local, and not indicative of any general disorder. This was certainly true of the common forms of stomatitis; in the ulcerative, and especially in the gangrenous form (noma), enfeeblement of the general health played a large part, though he thought it very doubtful whether vitamin deficiency was a factor. Speaking generally, Dr. Hutchison was of opinion that the oral manifestations of general disease in childhood were, except as affecting the teeth, neither numerous nor important, just as the alleged effects of oral disease on general health tended to be over-stated.

The Chairman said that he rather gathered from the remarks of Dr. Hutchison that the oral manifestations of general disease were neither marked nor of very great value for diagnostic purposes. The reason for this must be connected with the great resistance of the oral tissues to trauma and to bacterial invasions of all kinds. He wished to point out the service that an ordinary dental surgeon could render in the course of his work—he meant the dental surgeon who corresponded to the general practitioner in medicine. The dental surgeon did not see children very early, and he practically never saw them in an active stage of illness, but he might see the beginning of a growth or of some abnormality, hypertrophy or something of that kind, and this, of course, he would properly point out to the medical man. The speaker referred to

three conditions which the ordinary dental surgeon treated in children. The first was dental caries. Recent research seemed to prove beyond doubt that caries was due to the presence of certain organisms, but this was not a sufficient factor, otherwise every tooth would become carious. There was an unknown factor behind, possibly some endocrinal disturbance upsetting the ordinary immunity to bacterial infection. The second condition was periodontal disease. Here again there was a suspicion that something more lay behind the actual infection—something in the "soil" or "climate" as distinct from the "seed." The third condition was dental-facial irregularity—the particular department of the orthodontist. This condition might arise accidentally, or might be due to some fundamental disturbance of growth. Orthodontists told them that the more one looked for these innate disturbances of development the younger were the children in whom they were found. If the separation which normally occurred between the temporary teeth was retarded the child would have an irregular set of permanent teeth, but what the retarding condition was it was difficult to say; it must be something of a general nature. One of the greatest services a dental surgeon could render was to keep a careful watch on the development of the children who came to him from time to time, and to report anything abnormal to the parents or to the medical man.

Dr. H. C. CAMERON said that so far as it was possible to classify children into types—and the types were mainly determined in inherited peculiarities, assisted no doubt by faults in hygiene and diet—a distinction could be made between two common types of children, in one of which the teeth were found almost habitually faulty, and in the other the teeth, though with many exceptions, were usually well formed and well erupted and with good enamel. The type of child in whom caries was prone to occur was the child with a high content of lymph in the body, a round, plump child, often with very highly coloured cheeks, and a considerable tendency to overgrowth of the lymphatic structures. Such a child was specially likely to have inherited a tendency to catarrhal infections, and he thought the repeated catarrhs, acting on the erupting processes carried on in the normal organ, did from time to time result in that normal organ working badly, and caries was the result. It was very common in these children to find the molar teeth, not erupted vertically, but almost lying on their side, so that the grinding surfaces met at their edges and not surface to surface. The other type of child—the child who always seemed to have good teeth—was the child of intellectual inheritance, with metabolic instability, an ancestry of gout, migraine, asthma, and eczema, very often a pale, thin child, and much subject to vomiting and like troubles. This type of child seemed to have, as a rule, good teeth, with good enamel. A further point was with regard to the use of the jaws. Mothers were commonly instructed at the health centres to allow their children to bite hard food, but it always seemed to him that the child who developed well, who learned to walk early and speak early, learned also to bite and use the jaws early, whereas the child whose infancy had been punctuated by catarrhal complaints was likely to walk late, talk late, and also use the jaws late. In corroboration of this was the fact that children who had brain affections, having perhaps suffered cerebral injury at birth, and on the neuro-muscular side were very slow, nearly always gave an immense amount of trouble on account of their teeth.

Dr. DAVID NABARRO confined his remarks to teeth in congenital syphilis. He said that when people talked of Hutchinsonian teeth they usually had in mind the obvious appearance, and such instances were really quite common, but there were also other less marked types of Hutchinsonian teeth which were not at all uncommon but often escaped recognition. Often in children on whom, on account of suspicion arising from some other circumstance, a Wassermann test had been done and had proved positive, he had found on making a closer examination that the teeth were partially Hutchinsonian. In his experience also, when the Hutchinsonian teeth were found in the upper incisors, the lower incisors also had a very characteristic appearance, small, with a convex anterior surface, and spaced often like little tombstones sticking out of the jaw. The records of 208 cases of congenital syphilis in children over the age of 7, obtained at his hospital, showed that 32—about 15 per cent.—had typical Hutchinsonian teeth, but of the whole 208 only 93 had normal teeth, so that in more than half the cases there were teeth which made one suspect the presence of disease. He had had twelve cases of ulceration of the palate during the last twelve years, so that this was not a common condition though it was characteristic when it occurred. In only one of these twelve cases did he find Hutchinsonian teeth though in two others there was a "tombstone" appearance. The positive Wassermann reaction was very persistent in these cases of ulceration of the palate.

Mr. F. N. DOUBLEDAY mentioned a case in which an abscess on a temporary tooth had caused infection of the crypts of the permanent teeth beneath. This condition was not really osteomyelitis of the jaw in the sense in which one looked upon that condition in the adult, but he mentioned this occurrence of infection of the crypts in the hope that someone might have had more success than he in dealing with it. He also described a case of infantilism in a woman 18 years of age, who had all the appearance of a child of 7 or 8. She played with childish things, her stature was that of a child, and she had a childish dental condition. The speaker sent her to a medical colleague, who put her on dried thyroid extract, and she began to grow, and the teeth erupted perfectly well. In his mind one of the most serious manifestations of general disease in the mouth of a child was dental caries. This was often directly induced by bad advice given by medical practitioners. Mothers often quoted to him a medical practitioner as their authority for giving their children sweets. The practitioner had told them that this was an easy means of raising the carbohydrate part of the diet. He believed that the result was gastro-intestinal stagnation, and that such stagnation accounted for a large number of the cases seen in out-patient departments. It was very largely brought on by an overloading with sugar from youth up.

Dr. ALEXANDER LIVINGSTON remarked that there were two types of gum margin inflammation, one of them purely local, and the other, in his opinion, part of a general lowering of resistance, accompanied by constipation or diarrhoea or other systemic upset. Gum marginal redness was largely a local condition, but a certain group of children presented the more general state which he thought might be attributed to one or more of four causes: generally lowered resistance, calcium shortage, vitamin or sunshine deficiency, or Vincent's fusiform and spirochaete infection. Occasionally the condition went on to a gingivitis or stomatitis, and sometimes to noma. The teeth of children, the speaker added, were extraordinarily interesting and important. The teeth of a child of 6 might be said to give the child's past history, and the mucous membrane of its gums its present condition.

Mr. HAROLD CHAPMAN regarded irregular teeth as an ill development of the maxilla and mandible. There had been an increasing tendency in recent years to regard irregular teeth as one sign of some more deeply seated abnormality, but if there was any foundation for such a view it was particularly appropriate that it should be considered by the two Sections now meeting. What were the causes of irregular teeth, and were such causes also indicative of other physical defects? Were irregular teeth oral manifestations of other diseases in children? Irregular teeth occurred in children of all classes of society, but their incidence in families was peculiar. In some families certain children had irregular teeth and others perfect teeth from the point of view of regularity. In another family all the children might have irregular teeth. The most perfect regularity of teeth in all the members of the same family which he had ever seen was in a family of nomads, who lived under as primitive conditions as one could find in this country to-day.

Dr. ROBERT HUTCHISON, in his reply, took up the question of the effect of sugar on teeth. He was prepared to admit theoretically that sugar might be expected to be a factor in the production of caries, but sugar was an

extremely valuable food for the child, and it might be worth while to pay the price in a certain amount of dental caries. To say that sugar caused gastro-intestinal stagnation was, from a medical point of view, "bosh." Whatever else this unfortunate article of diet could do, it could not do that. One speaker had described a new variety of marginal gingivitis which apparently was due to all the pathological fads separately or collectively, including vitamin and sunshine deficiency—the *dernier cri*—calcium shortage, and Vincent's condition. He was extremely doubtful about *plural causation—and such causation!*

THE MEDICAL SERVICE IN WAR AND PEACE.

AT a meeting of the War Section of the Royal Society of Medicine, on April 11th, Major T. J. MITCHELL, R.A.M.C., read a paper on man-power and the medical service in relation to some of the principles of war.

Major Mitchell discussed the part played by the medical service in war with reference to the concentration of superior force, moral and material; economy of force; mobility, and co-operation. Its duties extended beyond the care of the sick and wounded, the preservation of the health of the troops, replenishment of medical stores and equipment, and the collection and evacuation of sick and wounded; they included also the decreasing of the number of deaths from wounds, reducing the number of permanently disabled men who would become a justifiable expense to the State, the shortening of the time spent in hospital, and promoting the speedy return to duty of as many men as possible. (The cost to date in payment of pensions and the administration of the Ministry of Pensions was over £665,000,000.) An efficient medical service resulted in a considerable saving to the State of both men and money. The medical service in an army, though wholly *humanitarian*, was yet of great military importance, since it played an active part by supplying reinforcements. Statistics showed that at one time or another during the great war the medical service was called upon to deal with the sick and wounded of a force with an average *strength*, including labour units, of nearly 3,500,000. Moreover, operations were conducted in every variety of country and climate, and in Eastern theatres of war in particular an important factor contributing to the success or otherwise of the campaign was the number and well-being of native followers. Broad questions affecting recruiting, billeting, training, rations, the provision of hospitals and other essential medical units opened up a field of research. Specialized types of transport and equipment must be considered to meet the varying needs of different theatres of war. Admissions for disease far outnumbered those for wounds in Eastern countries. Native followers, their needs and customs, afforded scope for a sociological study of far-reaching importance if campaigns in tropical countries were to be carried on without an extravagant expenditure of men and money. Practical application of the principles of medical organization in the field produced better moral among the troops; increased mobility of the army; the early return to duty of trained men who had been slightly wounded, thereby assisting in the concentration of superior force; monetary saving to the State; *and increased confidence* among relatives at home. To attain these ideals, however, there must be co-operation between the medical service and the general staff and other branches of the army. Certain obstacles always confronted the medical staff officer: the secrecy maintained by the general staff *on matters* affecting medical arrangements; its unwillingness to estimate the probable number of casualties and where they might be most numerous; and the locating of medical units. The ability of the medical service to help the general staff, their men, and the State depended upon the information given. For the supply of extra units and personnel, close co-operation was required with the adjutant-general's branch of the staff, and with "Q" branch on matters of transport. It was the duty of the medical service to make it clear that their requirements were not made haphazard but were calculated on definite factors, such as estimated battle and sick casualties, the rate of evacuation, and a small percentage for "crisis" expansion. Failure to appreciate this need for expansion, in the matter of transport, usually led to a breakdown of the medical arrangements, disorganization, and the evacuation overseas of slightly wounded trained soldiers, with consequent loss to the army and expense to the State. From the point of view of man-power the number of men returned to duty in the theatre of operation was all-important. The better the arrangements to collect cases without delay, and the more adequate the provision for their reception, treatment, and evacuation, the greater would be the mobility of the army and the economy of force. The medical statistics of the Western front had shown that the admissions to hospital numbered almost two million wounded and over three million for other causes; of these admissions, roughly 80 per cent. wounded and 93 per cent sick returned to duty in some capacity. The total returned to duty was equivalent roughly to sixteen armies. These figures bore eloquent testimony to the value of the practice of surgery and medicine and the allied special branches, as well as to the undoubted benefits of measures to prevent disease in an army; here success was limited by knowledge and the application of methods. While other branches of the army usually included in their paper schemes definite medical proposals, in actual preparations for war they found it difficult to apply these proposals. Bitter experience in Mesopotamia proved the inadequacy of the regulation that the officer commanding a unit or force was responsible for the sanitary conditions of that unit or force. Diarrhoea, colitis, and dysentery were among the greatest causes of sickness in that campaign, despite the constant issue of orders on the preventive measures required. When attacking troops captured a Turkish position they usually encamped on its site, one of the foulest spots imaginable; consequently the admission ratio for these diseases grew greater than that of battle casualties. It was not the decision to encamp on that position that was questioned, but the fact that all knew the inevitable results, were content to let them ensue, and, it seemed, were still content to let the same thing happen again. It was too much to expect tired troops to make a camp sanitary, but insanitary conditions could be made good if a fresh sanitary battalion were hurried to the spot. When it was realized that in Eastern theatres of war, if not in all, disease was a greater enemy than the human foe and took a greater toll of casualties, both men and money would be saved by proper equipment to fight against it. It was the plain duty, therefore, of the medical service in times of peace to try to convince others by hard facts, to examine their teaching and training, and to be ready to ease the suffering and save men for the fighting forces.

CROWN GALL AND CANCER.

A LABORATORY meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine was held at the London School of Hygiene and Tropical Medicine on April 6th, with the President of the Section, Professor R. T. LEIPER, in the chair.

During the evening Professor WILFRID ROBINSON read a paper on some features of crown gall in plants in reference to comparisons with cancer. From time to time, he said, comparisons had been made between tumour-like growths in plants and tumours in animals and man. Such comparisons on analysis proved to be more apparent than real, if only because of the profound differences in cellular construction and manner of growth. In recent years, however, Erwin Smith in America had expressed the opinion that the characteristic growths in plants known as crown gall were comparable to malignant tumours, particularly as he had observed what he considered to be metastases in this condition. Although he had isolated bacteria from these tumours, Smith had failed to locate them in the diseased tissues by direct microscopical observation. More recently, Blumenthal and other German workers has isolated from the margin of human tumours a bacterium apparently identical with that responsible for the plant condition (*Bacterium tumefaciens*), and at least one of his strains had proved capable of producing crown

gall on sunflowers. Moreover, Blumenthal claimed to have produced tumours in healthy animals by inoculation with the same organism. Using a strain of this organism isolated from chrysanthemums, Mr. Walkden and Professor Robinson had carried out experiments which suggested that Smith's comparisons could not be accepted as valid and which showed why Blumenthal's work could not be accepted as proving that a similar organism was responsible for malignant diseases in man and animals.

The secondary growths described by Smith did not occur naturally on plants, but resulted only from experimental inoculation. The natural growths were globular swellings with a rough surface bounded by superficial layers of dead cells, and the bacteria were present in abundance on the surface. The organism could only produce galls after wounding. It entered the intracellular spaces and, adjoining the lines of invading bacteria, cells and tissues, normally inactive, were stimulated to repeated division. Control shoots cut similarly did not thus grow. In these rough-surfaced galls the later development of the swelling was partly due to the active presence and multiplication of *Bacterium tumefaciens* on the rough external swelling of the gall. The so-called secondary tumours arose when the inoculations were made by needle-pricks near the growing points of actively growing shoots. A number of leaf-rudiments were affected by the needle-prick, and as the growth of the plant proceeded the injuries which developed galls became widely separated from one another. Many such galls had a rough surface, but some were smooth. They were not due to tumour strands, as Smith suggested, but to the presence of bacteria in the air spaces. The bacteria were either carried by the growth of the plant to some distance from the original point of entry or migrated actively in the intracellular spaces. Although regions infected by the migrating strands of bacteria superficially resembled invasive tumour strands, the cells were merely altered *in situ* and there was no migration of cells. This could be observed with particular ease in tobacco plants. Other features of crown gall, such as the apparent teratomas, and the apparent transformation of the structure of one organ into another as a secondary effect of bacterial activity, were equally invalid for comparison with malignant tumours in animals and man. Riker and Kustur had reached similar conclusions, but others had drawn the amazing conclusion that *Bacterium tumefaciens* or similar organisms occurred in human tumours, and that when isolated these organisms could produce not only galls on plants but tumours in animals. In no case, however, had these workers succeeded in isolating the organisms anew from the tumours of the diseased animals. That it should be possible to isolate organisms similar to *Bacterium tumefaciens* from the necrosing margin of tumours was not surprising in view of the large number of different bacteria there.

There thus, continued Professor Robinson, seemed little if any justification for Smith's comparisons or for Blumenthal's conclusions that some connexion existed between crown gall and animal tumours. There were, however, certain features which plant and animal diseases had in common. In both cases cells and tissues were stimulated to active atypical proliferation, and a real insight into the nature of these changes in crown gall might throw light on the changes taking place in the cells of animal tumours. Warburg held that this problem was essentially one in cellular physiology. He had studied the energy-liberating reactions in rat sarcomas and carcinomas, and in fowl sarcoma measured the fermentative changes in the tumour tissue. He found that this fermentative activity resulting in lactic acid production was a property of all non-necrosing tumour tissue, and that such tissue showed this property irrespective of the presence of oxygen. In the absence of oxygen all body cells showed fermentation, but only embryonic tissues showed fermentation at all comparable in magnitude with that of tumour tissue; this was masked in the healthy embryonic tissue by active respiration. Warburg concluded that in tumour tissues the oxygen respiration of growing cells was electively injured, while the fermentative activity still proceeded. Poisons and other injurious substances acted similarly and *in vitro* tumour cells occasionally arose. Usually, however, the effect of injuring respiration was to cause the death of the tissue. In plants lack of oxygen often resulted for a time in cell proliferation, and it might be of significance that *Bacterium tumefaciens* was strongly aerobic. Thus it was possible that in the intracellular spaces it modified the oxygen relations of the cells and caused proliferation. Whether the metabolism of the plant tissues in crown gall was similar to that in animal tumours had still to be seen, but it appeared possible that in their cellular physiology plant galls might have at least some points in common with animal tumours.

Dr. ARCHIBALD LEITCH thought that comparisons between plants and animals were rather illusive. He considered that the most that Blumenthal had ever done was to produce a granuloma, and a poor granuloma at that. It was even doubtful if his organism was the same as that of Smith. He agreed with Professor Robinson that there was no analogy between crown gall and animal tumours.

INFLUENCE OF RADIATION ON THE GROWTH OF TUMOURS.

AT a meeting of the Section of Electro-Therapeutics of the Royal Society of Medicine on April 8th, Dr. G. B. BATTEN presiding, three communications were made describing experimental work on the growth of tumours in tissues exposed to *x* rays and radium.

Professor SIDNEY RUSS spoke of some work which he and Miss G. M. Scott had done in the Cancer Research Laboratories of the Middlesex Hospital. He said that it was known from previous experiments that rats which had been exposed to repeated small doses of *x* rays and afterwards had been inoculated with Jensen's rat sarcoma did not grow the tumour as quickly as non-irradiated rats. One investigator, Murphy, had found that after purely local irradiation of the skin of mice, intracutaneous inoculations of the tumour rarely grew, but with subcutaneous inoculations there was very little difference between the growth in the treated mice and in the controls. As these observations had some bearing on the therapeutic use of *x* rays and radium, Dr. Russ and his colleague made further experiments from which again it seemed clearly indicated that the implanted sarcoma of the rat did not grow at the normal rate in the area which had been given a suitable dose of radiation. These experiments, which he described in detail with the aid of graphs, had been continued. Young rats had been inoculated on the flank with small pieces of Jensen's rat sarcoma, and three or four days later the graft was covered with a lead disc and the surrounding tissue exposed to a square radium capsule for varying periods in different cases. Half-way through each exposure the capsule was turned through an angle of 45 degrees so that the irradiated area might be more or less circular. In some cases control tumours were grown in the same rats, in others in different rats, but in all cases the control tumours were the larger. The series of observations on more than 100 rats suggested that radiation of the skin distinctly hindered the growth of the tumour. Finally this was tested in a more exact fashion. Each rat was covered with lead thick enough to stop the *x* rays used in this experiment, except over two areas. The rats were then exposed to moderate doses of the rays while under an anaesthetic. In some cases they were inoculated with Jensen's rat sarcoma before the *x*-ray exposure, but in most cases this was done three or four days afterwards, and the inoculation was made as nearly as possible in the middle of the screened area directly between the two exposed sectors. Jensen's rat sarcoma was found to grow much more readily in the normal areas, and in many cases where the irradiated area was eventually invaded by the tumour the growth was much flatter than in the normal regions. The tumour in its growth avoided the irradiated areas. All the rats in these experiments were inoculated in the flank. Normally Jensen's rat sarcoma in this position grew more or less spherically, with perhaps a tendency to track into the axilla and towards the chest, but one *x*-rayed sector was between the nodule and the axilla and the other directly below it, and the tumour grew more

readily towards the chest and avoided the x-rayed area near the axilla. The general result of the experiments was to show that the tumour grew more readily in normal tissues than in irradiated ones, irrespective of position.

In a further communication Professor Russ and Miss Scott described some work on the action of "radon seeds" on tumour and liver cells of the rat. The term "radon seeds" denotes a small glass tube, 3 to 4 mm. long, filled with radium emanation. The glass walls are very thin, so that not only do all the gamma rays get through, but a large proportion of the beta rays also. Jensen's rat sarcoma and the normal rat liver were used, and the seeds inserted for varying periods vertically and into the surface of the liver, leaving the top point just visible. These experiments were again described and illustrated in detail, and the general conclusions of the investigators were that limited regions of destruction were caused by inserting "radon seeds" into tumours and livers of rats, that the extent of the damage depended much more on the amount of energy absorbed than on the actual intensity of the radiation, and that the cells around the blood vessels appeared to be protected to some extent from the damaging effects of the radiation.

Dr. J. C. MOTTRAM, director of the Cancer Research Department, Radium Institute, London, also brought forward a contribution describing somewhat similar experiments, and bearing out the contention that tumour cells did not grow as well in irradiated tissues as in non-irradiated. He said that since radium and x rays were first used for medical treatment about twenty years ago a large number of facts had been accumulated, but so far no satisfactory theory which would string together a great number of these facts and possibly assist the clinician. Now that he had a theory had been propounded. He thought The theory was that the observed effects of the radiation on living tissues were to be explained by adding together the results of direct action on the cells and of interference with the blood supply. Radiation, he said, had a profound effect on the blood vessels. This could be demonstrated by a simple experiment on the ear of a rat or a rabbit. If one ear of the animal was given a two hours' exposure to beta radiation no effect would be observed during the first two days following the radiation, but on the third day the ear which had been exposed would be at once pinker and bluer than the other ear, and after pressure the blood would return more quickly. After five days the only change would be a remaining blueness, and after six or even days there would again be no difference between the ears. Fast-growing tumours were much more sensitive to radiation than slow-growing. The question was whether this difference was due to any greater sensitiveness of the cells of the tumour or to some other reason. He proceeded to describe experiments in which small pieces of tumour had been taken out and irradiated between mica and then put into mice. The result of the radiation was to cause the tumours to grow very much more slowly, but the tumours so treated were much less sensitive to a second dose of radiation. The changes seemed to be explicable, not by increased sensitivity of the cells to radiation, but by some other factor, probably the blood supply. There was no evidence that tumour cells were necessarily more sensitive to radiation than normal cells, and indeed the evidence of one observer, not perhaps convincing, was that actually the tumour cells were more resistant. The other factor was the vascular supply, which, if it were interfered with by radiation, might be expected to operate more severely in tumour tissues than in normal tissues. Such interference also was likely to influence more profoundly the fast-growing than the slow-growing tumours. To measure the vascular supply of a tumour was not easy. In slow-growing sarcomas one found quite a large number of well formed vessels running through the tumour. This factor might be held to explain the difference in the effect of radiation on tumours of various kinds, non-malignant and malignant, and situated in different regions, vascular and relatively avascular. A great number of clinical and experimental findings might be correlated with this idea that it was not only or chiefly the sensitivity of the cells which explained the action of the radiation, but the interference with the blood supply to the growth.

ULTRA-VIOLET RAY THERAPY.

AT a meeting of the Brighton and Sussex Medico-Chirurgical Society on April 7th, with the President, Dr. E. RIVAZ HUNT, in the chair, Dr. J. STANLEY ELLIS, in a paper on ultra-violet therapy, gave a brief history of the development of treatment by natural and artificial sunlight, and discussed the advantages and disadvantages of both methods. He concluded that artificial sunlight therapy bore the same relation to natural sunshine that synthetic drugs had to the crude drugs. The various wave-lengths of the electro-magnetic spectrum were shown, and the characteristics of the ultra-violet range were considered in detail. The definite photo-electric, photo-chemical, and fluorescent effects of the rays on the tissues were the basis of the profound physiological changes now demonstrable. After citing the effects of the rays on cholesterol, on the nerve endings, and on the production of pigment, all of which were concerned in the beneficial action of light therapy, the various conditions which responded to treatment were shown to fall naturally into four or five groups where the above physiological changes and others were most marked. Dr. Ellis added that certain drugs and endocrine extracts were activated by the rays in the human body, and emphasized the need of collaboration between the physician and actino-therapist. He feared that this form of treatment was in danger of discredit owing to the too ardent claims of enthusiasts: it was not a cure-all, but in the great majority of cases it was essentially an auxiliary procedure.

Diarrhœa in Tabes.

Dr. ROWNTREE CLAPHAM showed a woman, aged 37, who two months previously had come to hospital complaining of chronic diarrhœa of three years' duration which had become much worse in the previous six weeks. There were about nine motions during the day; they were quite painless, but she was losing weight rapidly. Examination of the abdomen and rectum revealed nothing except slight weakness of the sphincters. Examination of the nervous system, however, showed that this was a case of tabes with Argyll Robertson pupils, loss of ankle- and knee-jerks, and commencing perforating ulcers of both feet. The gait was normal, Romberg's sign was absent, and there was no inco-ordination. There was some analgesia and paræsthesia of the feet, the outer side of the legs, and the inner side of the arms. The Wassermann reactions of the blood and cerebro-spinal fluid were positive; the spinal fluid cells numbered 200 per cubic millimetre, globulin was in excess, and the colloidal gold reaction was 4332210000. Under antisyphilitic treatment the diarrhœa had improved, and the patient now had only two motions a day.

JAMES MACKENZIE INSTITUTE.

Delayed Resolution.

ON March 1st Dr. MAIR read a paper on delayed resolution in pneumonia. He distinguished an alveolar and an interstitial type of lesion, the former being characteristic of unresolved and recurrent pneumonia, while the latter was represented by pulmonary fibrosis. The symptomatology of unresolved pneumonia in the adult was reviewed, the lecturer specially emphasizing the loss of weight, even amounting to emaciation, which might result from this disease process. Illustrative cases from the Institute records were quoted. In one of these the signs of unresolved pneumonia were still evident, both clinically and radiologically, five months after the onset of illness. The symptoms in children were somewhat different from those found in the adult, the cardinal symptom being paroxysmal cough, often associated with cyanotic attacks. Failure of nutrition and some degree of exhaustion were almost constantly present. Cases of unresolved pneumonia and of recurrent pneumonia in children were reported, and the lecturer stated that danger to life appeared to arise, not primarily from the pneumonia, but from the repented strain on the heart. One child died of exhaustion in its fifth attack. The difficulty of recognizing cases of interstitial fibrous pneumonia was emphasized. Symptoms might be almost lacking in this disease, beyond slight cough and some loss of efficiency, unless the condition was of such long standing that cardiac displacement had resulted.

Reviews.

LISTER AS SEEN BY A STUDENT.

DR. JOHN RUDD LEESON entered as a student at St. Thomas's Hospital, London, in 1871. After two years in its medical school he, on the advice of Dr. Murchison, migrated to Edinburgh. In *Lister as I Knew Him*[1] he now records the impressions made on him by his service in Lister's wards of the Royal Infirmary. No greater contrast could well be imagined than that offered by the conditions under which Dr. Leeson worked in the two institutions. St. Thomas's Hospital had just been erected, almost regardless of expense, in an open situation, with every improvement that commended itself to the late Sir John Simon, then the leading authority on all questions of hygiene, including hospital construction. The nursing was carried out by Florence Nightingale's own nurses. Everything seemed to be in favour of the patients' quick recovery from injuries and operations. Yet it was found that the new surgical pavilions at Lambeth were little if any more healthy than the ancient wards of the old building in the Borough of Southwark. On the other hand, Lister's wards in the Edinburgh Royal Infirmary were ill ventilated, ill lighted, crowded, and not over-clean. The building had not been designed for a hospital but for a school. It was old, situated in a low and crowded poor district, and, in short, seemed to be as ill suited to its purpose as St. Thomas's was well suited. The nursing staff had little training, and its members were ill educated and uncultured, unlike the trained and refined ladies of Miss Nightingale's school. In fact, a good deal of the nursing was done by the surgeons' dressers and clerks, of whom there were fifteen besides a house-surgeon. Yet the diseases which at St. Thomas's rendered the surgeons' efforts vain were banished from Lister's wards. The contrast was naturally staggering to the English student, who soon became one of the devoted band of dressers, and afterwards clerk. Lister's care of detail extended beyond the operating theatre, and he himself attended to much that would now be left to a nurse. This was one of the great secrets of his success, and the neglect of this, as well as misunderstanding of principles, was the secret of the failure of many of his contemporary surgeons in Scotland as well as England to obtain good results from the antiseptic method. Dr. Leeson tells us that although at almost every visit Lister was accompanied by foreign surgeons, eager to note every detail, his senior colleagues on the staff of the Infirmary took no interest and never entered his wards. London surgeons have no cause to look back with pride on the reception accorded to Lister and his methods by their predecessors, but Glasgow and Edinburgh are in no position to throw stones. It is clear from Dr. Leeson's pages that Lister, with all his kindness of heart, was a shy man, and that he never succeeded, even if he wished to do so, in breaking through the veil of constraint which separated him from his pupils, who nevertheless revered him, although their reverence was not untinged with awe.

This interesting book is well illustrated, some of the plates being taken from the late Professor John Chiene's book *Looking Backwards*.

PYORRHOEA ALVEOLARIS.

IN his work on *Pyorrhoea Alveolaris*[2] Mr. STEADMAN retains the old and oft-abused nomenclature because "it is exceedingly difficult to find a name which is really suitable, and the old term 'pyorrhoea alveolaris'—bad as it is—appears upon the whole to be as good as any other." Most medical practitioners will agree that even a bad name is better than another change, and will be grateful to Mr. Steadman for acknowledging that he, at any rate, can invent no better term. The author, who lectures on bacteriology at the Royal Dental Hospital, London, would divide pyorrhoea into (1) the germ-carbohydrate-stagnation type; (2) the atrophic type; (3) the acute infective type. While we acknowledge the simplicity of such a classification we cannot agree that he makes out a good case. The third type, by common consent, stands apart as a fuso-spicillary infection, but the first two "types" so commonly coexist, or in course of time develop one into the other, that no clinical distinction of type can be made.

In the etiology of pyorrhoea the author finds a place for "traumatic occlusion," but we should have preferred an example in which the affected teeth were regularly placed. Again, peri-apical infection through the blood stream does not seem to have been proved in the case quoted by the author: extremes meet, and we should have been at the other extreme (local peri-odontal infection) in explaining the clinical course of the case quoted. The importance to the dentist of substantiating the existence of traumatic occlusion and of peri-apical infection through the blood stream must be our excuse for direct criticism of these points.

The major part of the book is devoted to a discussion of the sequelae of pyorrhoea, and here the author seems to have forgotten he started out to discuss pyorrhoea and (greatly, we think, to the reader's advantage) has included all sources of dental sepsis. He has a wide clinical experience, and keeps careful notes, with the result that diseases as divergent as alcoholism and cancer have their appropriate clinical illustration. Syphilis is relegated to a minor place in the causation of chronic glossitis, and in general we may say that the author has a very just appreciation of the part played by dental sepsis in the production of disease, and presents his case in a restrained, and therefore the more convincing, manner. The pages on insanity might perhaps be curtailed.

In the chapters on treatment the author begins with the preventive treatment of the expectant mother, and carries the argument runs through infant-feeding, adenoids and mouth breathing, regulation of teeth, to the actual treatment of the condition when present. In adults we gather that the author is inclined to radical treatment.

Dr. Murray Levick adds a note on the value of ultra-violet radiation in dental sepsis, especially in raising the immunity of the body to bacterial invasion.

We wonder what "negatory" (p. 153) means, and we wonder how removal of teeth accounts for the incidence of pyorrhoea in childhood (p. 14).

The book will stimulate thought and interest in the problems of dental sepsis, both among medical and dental practitioners.

THE EVOLUTION OF MAN.

WE welcome a second edition of Professor ELLIOT SMITH'S essays on *The Evolution of Man*[3]; the first edition was published less than three years ago, and the volume had to be reprinted within six months.

In the new edition certain parts which were regarded by the author as not relevant to the general purpose have been omitted, but additions, both considerable and highly important, have been made. In the course of a most interesting discussion of the question of right- and left-handedness, it is indicated how the asymmetry of the human cerebral hemispheres "confers upon one hand, usually the right, a greater aptitude for the attainment of skill than the other." The author also marshals in orderly sequence the factors which led up to the adoption of the erect posture, and shows that it was not the cause of man's intellectual pre-eminence, as has so often been assumed. The erect attitude, as Professor Elliot Smith so definitely establishes, was itself made possible by cerebral development.

Perhaps the most valuable and fascinating addition is a very full consideration of the acquisition of skill and its significance and influence upon the evolution of man. Evidence is presented to prove definitely how the ability to perform skilled movements emerged, and how, having been established, it exerted profound influences upon the further development of the neopallium.

[1] *Lister as I Knew Him.* By John Rudd Leeson, M.D., C.M.Edin., M.R.C.S., F.L.S. London: Baillière, Tindall and Cox. 1927. (Demy 8vo, pp. viii + 242; 7 plates. 8s. 6d. net.)

[2] *Pyorrhoea Alveolaris: Its Ætiology, Pathology, Symptoms, Sequelae, and Treatment.* By F. St. J. Steadman, D.P.H., L.R.C.P.Lond., M.R.C.S., L.D.S.Eng. London: Henry Kimpton. 1927. (Roy. 8vo, pp. xv + 263; 42 figures, 36 plates. 25s. net.)

[3] *The Evolution of Man: Essays* by G. Elliot Smith, M.A., M.D., Litt.D., D.Sc., F.R.C.P., F.R.S. Second edition. London: Milford, Oxford University Press. 1927. (Demy 8vo, pp. xii + 165; 47 figures. 12s. 6d. net.)

References to recent advances in knowledge and anthropological discoveries have been incorporated, and a very complete account of the Taungs ape is presented. The number of illustrations has been tripled in this second edition; they are all exceedingly clear and of high quality, and enhance appreciably the value of the book. The general descriptions and discussions are so simple, and technical terms have been avoided wherever possible with such remarkable skill, that the essays may be followed readily by the interested layman, as well as by the biologist and the anthropologist. The first edition has already proved itself to be a popular and valuable textbook, both in this country and abroad, and the new edition is likely to have an even wider circulation, and can be recommended most warmly to all interested in man's pedigree.

ALLERGIC DISEASES, INCLUDING ASTHMA.

DR. W. W. DUKE'S book, the first edition of which was reviewed last year (1926, i, 290), on *Allergy: Asthma, Hay Fever, Urticaria, and Allied Manifestations*,[4] has already passed into a second. In the brief preface he not only expresses his "sincere thanks to the editors and physicians who have so kindly reviewed this little book," but obligingly points out some of the additions necessitated since it first appeared. Among them are almost a hundred recent references added to the existing thirty odd pages of the bibliography. Considerable importance is attached to the observation that most normal persons can be passively sensitized locally by an intracutaneous injection of the serum of a hypersensitive individual, and that this sensitiveness is specific for the substance to which the donor is sensitive—for example, if the recipient takes an article of food which affects the donor, the area of skin sensitized, and that part only, responds. He also describes very briefly his modification of E. W. Phillips's intracutaneous treatment with pollens for hay fever, and states that it was always and rapidly successful.

Dr. Duke has done much work on the reactions caused specifically by physical agents, such as light, heat, cold, mechanical irritants, and indirectly by the effect of mental or physical effort. The illustrations of urticaria thus produced are very striking. Reference to the work on these lines by Sir Thomas Lewis and his collaborators during the last two years should find a place in the next edition of Dr. Duke's useful book.

GUY'S HOSPITAL REPORTS.

THE first quarterly instalment of the seventy-seventh volume of the *Guy's Hospital Reports*,[5] edited by Dr. ARTHUR F. HURST, now with the help of Mr. W. H. OGILVIE as assistant editor, contains eleven articles. One, entitled "Cases from Clinical," deals with eight cases of interest; five of them, being by the "clinicals" or student contributors, serve a valuable educational purpose not only to the readers but to the writers. The longest article, occupying nearly a third of this instalment, is that on extrauterine gestation at term by Mr. S. N. Evans, who from an analysis of 33 cases published in the five years 1920-24 concludes that the etiological factor in 67 per cent. of the cases is infection due to a previous pregnancy or abortion, and that in the remaining 33 per cent. there is only the rather unsatisfactory postulation of developmental defects and anomalies. Mr. A. W. Ormond reports cases of disc-like degeneration of the macula, occurring at about the age of 70, and due to senile failure of the capillary circulation in the retina; the article is illustrated by six coloured representations of the change. A form of encephalitis lethargica characterized by unequal pupils and loss of accommodation without any severe constitutional disturbance and without any other nervous symptoms is described by Mr. O. Gayer Morgan and Dr. C. P. Symonds. Mr. W. H. Ogilvie reports two cases of squamous-celled carcinoma occurring simultaneously in different parts of the body, and appends a list of papers dealing with two independent malignant growths in the same patient. Mr. E. H. Richards has investigated the microscopic conditions of the tonsils and the posture in forty-two children; he finds that hyperplasia of the tonsils is associated with a generalized hypotonic condition, whereas a purely inflammatory change is a comparatively local affection; his results confirm those of Misses L. Wills and J. Warwick. Dr. Arthur Hurst's activity and influence are extremely obvious; he contributes two papers on remedial exercises in asthma and on so-called gastric hypertonus and gastroptosis, and atonic dilatation of the stomach. Dr. F. A. Knott's article on the part played in pernicious anaemia by achlorhydria and intestinal infection deals with thirty-seven of the editor's cases, and Dr. J. A. Ryle's record of an instance of oesophageal spasm with severe anaemia (Plummer-Vinson syndrome) is clearly inspired by his senior's example.

VERTIGO.

DRS. J. LÉVY-VALENSI and E. HALPHEN have written a small volume with the title *Les Vertiges*,[6] which summarizes in convenient form the main facts concerning this interesting and difficult subject. The book is one of a series dealing with neurological and psychological subjects published under the direction of Professor Henri Claude and Dr. Lévy-Valensi. Vertigo is defined as an error of sensation under the influence of which the sufferer feels as if he himself or surrounding objects were animated by a gyratory or oscillating movement. All true vertigo they regard as directly or indirectly vestibular in origin, whether the cause be an organic change in the vestibular mechanism itself or a systemic toxin indirectly affecting this mechanism.

After a short description of the anatomy and physiology of the vestibular apparatus and its nervous connexions, a considerable part of the book is devoted to an account of the standard methods for the examination of labyrinthine function. The various clinical conditions in which vertigo is a prominent symptom are then discussed seriatim and their differential diagnosis is considered. The accounts of primarily labyrinthine, nervous, and general conditions associated with vertigo are brief and clear, and the volume is an excellent guide to the subject.

NOTES ON BOOKS.

THE demands made upon the nursing profession have undergone a profound change; the cause is probably twofold. In the first place, during the war, in the times of stress, sisters and nurses had to perform duties and undertake responsibilities which they had hitherto never been called on to discharge. Since the war the advent of women into the medical profession has broken down many old prejudices and stimulated a keener interest and sense of rivalry among the nurses themselves. For this reason we can recommend Mr. RUSSELL HOWARD'S book on *Surgical Nursing*,[7] which appears in its fifth edition and is brought up to date. The foundation of the book is a series of lectures on surgical nursing given to the probationers of the London Hospital. It gives a brief and concise account of the principles upon which modern surgical treatment is founded, especially from the nurse's point of view, and we may add that many medical students and junior qualified men would find its contents extremely useful to them in the wards. The active strides being made by surgery, with its tendency towards greater specialization, demand an ever-increasing knowledge on the part of the nurse, and it is essential that the nurse should understand the principles upon which the surgeon is working, so as to be the better able to render him efficient aid. Apart from carrying out instructions, the nurse must be prepared in cases of emergency to act and apply such treatment as may be possible until the arrival of the surgeon. Moreover, it is becoming more customary for nurses to carry out the preparation of the patient without special orders, and also to modify diet as circumstances demand.

[5] *Guy's Hospital Reports*, Vol. 77 (Vol. 7, Fourth Series), No. 1, January, 1927. Edited by Arthur F. Hurst, M.D., and W. H. Ogilvie, M.Ch. London: The *Lancet*. (Med. 8vo, pp. 1-126; 2 *coloured plates*, 32 figures. Annual subscription £2 2s. for volume of 4 parts; single numbers 12s. 6d. each.)

[6] *Les Vertiges.* Par J. Lévy-Valensi et E. Halphen. Bibliothèque de Neuro-Psychiatrie. Paris: A. Maloine. 1926. (Imp. 16mo, pp. ii + 118; 41 figures.)

[7] *Surgical Nursing.* By Russell Howard, C.B.E., M.S., F.R.C.S. Fifth edition. London: E. Arnold. 1926. (Cr. 8vo, pp. xx + 320; 27 figures, 12 plates. 7s. 6d. net.)

The thirteenth edition of *Madeira, Canary Islands, and Azores*[8] has been revised and brought up to date, and the author, Mr. A. SAMLER BROWN, is to be congratulated on improving still more a very valuable and interesting guide-book to these islands, which are rightly increasing their popularity as health and holiday resorts. The climate, history, geography, social conditions, means of transport, and such matters are dealt with comprehensively, and the book is illustrated with photographs, maps, and diagrams. Special attention has been given to the requirements of invalids of different kinds, and medical practitioners who wish for information in this respect will find the book helpful. It may be suggested that the subject of pronunciation deserves a little more attention, two short paragraphs on an otherwise blank page being intriguing, but inadequate for those who would like to arm themselves with a few phrases in Portuguese or Spanish before landing.

The second edition of Dr. HARRY MERRALL's little work on *Resistance to Disease*[9] differs from the first, which appeared about two years ago (JOURNAL, May 16th, 1925, p. 931), by the addition of a new preface and the prescriptions for some throat pigments.

THE HEALTH OF THE ARMY.

ANNUAL REPORT FOR 1925.

IN March, 1925, we reviewed the report on the health of the army for the year 1922, and drew attention to the delay in the issue of these annual reports. Since then, and within a space of little over twelve months, the reports for 1923, 1924, and 1925 have appeared, an achievement on the part of the Medical Department of the War Office which merits grateful recognition by all who peruse these reports before the interest in them has subsided. The report for 1924 came under review only nine months ago, and we have now received the report for 1925.[1] In this respect the Army Medical Service has forged ahead of the Royal Navy and the Air Force, and has drawn level with the United States Army Medical Department.

The 1925 report is similar in character and extent to that of the previous year. Both at home and abroad the health of the army continues to be satisfactory, reductions being noticeable in the admission, death, invaliding, and constantly sick rates.

The admission rate for officers, with a strength of 9,909, was 296.3, and the death rate 4.44 per 1,000, as compared with 284.4 and 5.86 in 1924. The corresponding rates for other ranks, with an average strength of 193,597, were 446.2 and 2.35, as compared with 484.7 and 2.8 in the previous year. The invaliding ratio was 11.12, as compared with 13 per 1,000 in 1924 and 14.5 in 1923. The constantly sick rate—25.7 per 1,000—also showed a decrease from 27.11 in 1924.

Among the causes of admission to hospital, malaria (10,019 cases) heads the list as in previous years, but the ratio has fallen from 71.0 to 51.8 per 1,000 of strength. Venereal diseases (8,591 cases) come next, and show a decrease of 600 on the admissions for 1924. Tonsillitis (6,008 cases), inflammation of areolar tissue (4,582), bronchitis (3,286), influenza (3,047), sprains (2,592), and sandfly fever (2,397) follow, in practically the same order as in the previous year, as the chief causes of admission, influenza alone showing any marked decrease in the ratio.

With the exception of the small garrison in West Africa, no command showed a ratio of admissions amounting to 1,000 per 1,000. In West Africa it was 1,016.8. The most marked reduction is in the Army of the Rhine, where the ratio fell to 289.7 per 1,000 from 345.9 in 1924 and 466.5 in 1923. The decrease cannot be attributed, as in the previous year, to a great reduction in venereal diseases, although the latter have decreased from 38.4 per 1,000 in 1924 to 30.7 in 1925. The health of the Army of the Rhine in 1925 was only equalled by the health of the comparatively small garrisons of Bermuda and Mauritius, and with the exception of these two shows the lowest admission rate of any other command.

The report contains many interesting notes on the chief diseases. Again we find that the amoebic type of dysentery preponderates. Of the total admissions for dysentery 67.9 per cent. were diagnosed as amoebic; but the report draws attention to the fact that special bacteriological investigations have resulted in more precise differentiation of the types of the disease. At the same time, it is difficult to get away from the impression that amoebic dysentery is the prevailing type east of Suez and bacillary the type west of Suez. In Egypt, for example, in 55 out of 62 admissions, 40 were bacillary and 15 amoebic, whereas in India 438 of a total of 725 admissions were diagnosed as amoebic. Against this, however, it must be noted that in one district, Poona, bacillary infection was the main cause of admission. Much stress is laid in the report to the importance of the investigations in relation to principles of prevention and treatment. It may be noted in this connexion that the prevention of bacillary dysentery by prophylactic vaccines has not yet become a practical proposition in the army; and that both forms of the disease are considered to be largely due to contamination of food by flies.

There were 218 admissions for enteric fevers, 184 of the cas occurring in India. Little light, however, is thrown on tl effects of prophylactic inoculations. Reports in this respe refer only to 5 cases at home, none of whom were inoculate and 9 cases abroad, exclusive of India, of whom 5 had bee inoculated. The only information regarding cases in India the statement that 86.5 per cent. of the officers and 95.3 pe cent. of other ranks had prophylactic inoculations; but to wha extent the 184 cases occurred amongst the non-inoculated is no recorded.

Venereal diseases, which in recent years have remarkabl declined in the army both at home and abroad, show a sligh further decline in 1925. The ratio for the whole army wa 44.4 per 1,000, as compared with 47.8 in 1924. In the home commands alone it was only 22.3. The chief cause of admission was gonorrhoea, admissions for other types of venereal disease being insignificant. Some interesting observations on the value of preventive measures are recorded. In Malta a decrease in the admission ratio from 41.4 in 1924 to 24.8 in 1925 is attributed to the establishment of preventive ablution centres in certain streets; and in Quetta, out of 6,057 men who used a central prophylactic treatment room in the bazaar, only 8 are stated to have developed venereal disease subsequently. Considerable research work in connexion with gonorrhoeal vaccines is also recorded in the report.

The only other group of diseases that are extensively dealt with are diseases of the digestive system. They formed the subject of special investigations by all modern methods of diagnosis and treatment. The number of admissions for gastritis, indigestion, duodenal and gastric ulcers, and appendicitis was formidable, and was responsible for a high constantly sick rate. The investigations were carried out in connexion with them by fractional test and barium meals, presence of occult blood, fluoroscopy, and radiography, and the results correlated.

As in previous reports since the war, special notes are included in the report for 1925 on the work of the departments of medicine, surgery, hygiene, and pathology. These are now a feature in the annual reports on the health of the army, and should be an encouragement to young medical men who are anxious for opportunities of good scientific and professional work to adopt an army career. A short account of dental work in the army is also of interest, and shows how this important service is growing.

The section dealing with the medical examination of recruits gives the number examined as 57,447, of whom 20,405, or 355.19 per 1,000, were rejected or discharged within six months of enlistment. The ratio in 1924 was 393.49. The chief causes of rejection, as in previous years, were deafness and ear diseases, loss or decay of many teeth, defective vision, heart diseases, and defects in lower limbs. As regards invaliding, middle ear diseases accounted for the majority of the cases, tuberculosis and valvular disease of the heart coming next in order. Other sections of the report comprise detailed statistics and notes on the health of the troops in each command at home and abroad, of gentlemen cadets, the boys' technical school, Beachley, and the women and children on the strength of the army.

British Medical Journal.

SATURDAY, APRIL 16TH, 1927.

THE PREVENTION AND CONTROL OF RHEUMATIC INFECTION IN CHILDHOOD.

IN the SUPPLEMENT this week is published the second report presented to the Science Committee of the British Medical Association by the Subcommittee set up in January, 1924, "to inquire into the steps which have been, and are being, taken in relation to the prevention, detection, and treatment of cardiac disease in children, and to make proposals in connexion therewith." The first report of the Subcommittee, which was published in the SUPPLEMENT for July 3rd, 1926, laid down certain general principles for the prevention and treatment of rheumatic heart disease in childhood. The present report furnishes the application of those principles to practical politics. Its object is to suggest in a more detailed form the steps which any national campaign against this disease should follow. In preparing these suggestions the Subcommittee had the valuable assistance of Dr. C. O. Hawthorne (Chairman of the Science Committee) and Dr. H. B. Brackenbury, and of Dr. J. Alison Glover of the Ministry of Health. Besides the material collected for the first report the Subcommittee examined a large mass of additional information prepared by its Honorary Secretary, Dr. Reginald Miller, who presents it in a summarized form in an appendix to the new report.

The reader of this second report cannot fail to be struck by two things. First, it deals rather with treatment than with prevention. This does not imply an underestimation of the supreme importance of prevention. It merely reflects the imperfect state of our knowledge of the causes predisposing to rheumatic infection, confessed by Dr. G. F. Still in his summary of the recent Medical Research Council report on the same subject.[1] It is possible that further research into environmental conditions may bring to light more definite bases for a policy of prevention. For the collection of the data necessary for such an investigation the Subcommittee favours voluntary effort rather than compulsory notification, having regard to the difficulties, administrative and clinical, by which the latter course would be hampered. In the meantime the Subcommittee has expressed in action its declared belief in the importance of preventing damp in dwellings by taking into counsel the Royal Institute of British Architects, who will doubtless report on the matter after giving it due consideration.

It is in the proposals for dealing with children already injured by the disease that the second great feature of the report stands out—namely, its preference for the co-ordination of existing agencies over the establishment of any new *ad hoc* service. Those agencies are the family practitioner, the school medical service, and the voluntary hospitals. The onus of making an early diagnosis falls especially on the first and the second of these, while the third can help here also by offering expert assistance. There is no need to set up new machinery for dealing with this part of the task. Indeed, the report emphasizes the unwisdom of any plan which would hand over the diagnosis of rheumatic infection in childhood to a specially appointed service of officers working in isolated clinics.

In the treatment of the disease, however, it is clear that the existing machinery is inadequate. Increased knowledge of the pathology of rheumatic heart disease has taught us that the infection tends to persist, often in a latent form, for periods of years. To meet this tendency the report proposes that a register of rheumatic children shall be kept so that the children may be re-examined periodically as far as is thought necessary. This is in accordance with the general trend of hospital policy in this country, and even more in America, where the "follow-up" organization is regarded as an essential part of every efficient hospital.

The final paragraphs of the report deal with another means of prolonged treatment in which America has taken the lead—more, we believe, owing to circumstances over which we have no control than to blindness or lassitude on the part of British clinicians. As long ago as 1912 Dr. F. J. Poynton, to whose unwearied labours on behalf of the rheumatic child the whole world stands in debt, said, at the Liverpool meeting of the British Medical Association, that he looked forward to the foundation of proper homes for the convalescence of the rheumatic child. So far as this country is concerned, however, these hopes were soon to be destroyed, or at all events deferred, by the European war.

The Subcommittee's first report included a valuable summary by Drs. G. A. Allan and A. P. Thomson of the provision already made in this country for the organized after-care of rheumatic children. From a perusal of this it is clear that there is as yet little accommodation for the prolonged institutional treatment of these children, and that the Subcommittee was justified in pleading for its rapid expansion. In the second report the lines upon which such accommodation should be provided are suggested: close touch with the existing voluntary hospitals, provision of means of education to run concurrently with treatment, and union with similar institutions treating other crippling diseases of childhood. No one expects to see miracles achieved by these methods, yet those who are most experienced in the treatment of rheumatic heart disease in childhood have borne witness to the possibility of arrest, and even of cure, in an appreciable proportion of cases if early diagnosis is made and treatment carried out over an adequate period. It is to the provision of these two essentials, chiefly by the co-ordination of means already in being, that the bulk of this eminently practical report is devoted, and we are confident that the medical profession in this country will not be slow to adopt its recommendations.

[1] See BRITISH MEDICAL JOURNAL, March 12th, 1927, p. 480.

STONEMASON'S LUNG.

AN interesting turn was given to the discussion on the perilous state of the stonework of the Palace at Westminster in the House of Commons on March 31st, when three Labour members raised the question of the effect on the health of the quarriers and dressers of the hard siliceous Darley Dale sandstone, recommended for the repairs by the Office of Works. A million pounds and more is to be expended over a period of fifteen years. The debate made a picture of what must have been the ordinary procedure in any guild-hall in the Middle Ages when an important building was to be erected, because we had an architectural sculptor, a builder, and a carpenter expressing

their views, the result of practical knowledge, on the importance of avoiding in the future the glaring faults of the past.

After the Thames itself, it is the Portland stone, of which practically all the public buildings except the Houses of Parliament are built, that gives London one of its chief beauties. Barry's design for a Gothic pile unfortunately required a stone which lent itself to elaborate undercutting and carving of statuary, pinnacles, and other ornament. He therefore discarded Portland stone, preferring a magnesium limestone from Anston in Yorkshire. Subsequently almost every mistake that could be made with this stone was made, such as face bedding—that is to say, placing the horizontal bed of the stone in a vertical position. The sculptors carved too well, and the smoky atmosphere of London, charged with sulphuric acid from the combustion of coal, shows no mercy to delicate stone tracery, with the result that, as a purely "safety first" measure, £37,000 has been spent simply on "hand-picking" the decayed portions. Portland stone was advocated by the Labour members, not only for its durability, but also because, as a limestone, it is innocuous, or nearly so, to the lungs; whereas sandstone is notoriously the building stone most productive of silicosis. Some interesting figures comparing these two classes of stone were given. Thus, as compared with a general phthisis death rate of 1.4 per 1,000 in the years 1901-10, the rate was 13.7 among 124 gritstone workers in Derbyshire and 7 per 1,000 among 426 stone workers (some in limestone) in the two Matlocks and Darleys. Among colliers in the same district it was 0.68. The Registrar-General's comparative mortality figures for phthisis for 1910-12 were also quoted—142 for all males between 25 and 65 years of age, 127 for granite dressers, 129 for limestone workers, and 451 for sandstone masons.

Nowhere in the memorandum drawn up by the Office of Works is the question of the healthiness or otherwise of working these stones mentioned, presumably because that aspect never entered the minds of the responsible parties. Attempt was made on behalf of the Office of Works to maintain that the figures were based on the census of 1910, and therefore could not be taken as reliable to-day. This is a familiar way of shelving an awkward question. Clinical symptoms do not alter when conditions remain the same, and it is an unfortunate fact that no means external to the worker—conditions, that is to say, over which he can exercise control—such as flexible ducts connected with fans to take away the dust, have been introduced into stone-cutting operations. It may be possible, however, to adapt the pneumatic tools now increasingly used to consume their own dust by means of the exhaust for the compressed air.

At any rate, the ventilation of this subject in the House of Commons will ensure now that the best brains are brought to bear on this very difficult problem. For a dozen years or more some scores of sandstone masons will be working within the precincts of the Palace of Westminster—ideally near the Chamber, therefore, for complaints to be heard and attended to. How many other dangerous trades would wish to be similarly placed!

It must have been obvious to those who raised the discussion that a self-denying ordinance in the case of the Houses of Parliament against the Darley Dale stone was illogical, if its use was not to be prohibited altogether. It was alleged, too, that Portland stone would cost three times as much. Still, Government departments have a way of cheapening at one end and making dearer at the other. It will be interesting to see if the official assurance is borne out: "We do not think that any injurious effects to the workmen will ensue from the use of this stone."

THE ACTION OF SALICYLATES.

THE value of the salicylates is apt to be underrated because these drugs are used for a wide variety of purposes, and the full importance of the aggregate of their actions and uses is not immediately obvious. They are, in fact, one of the most widely used and important groups of drugs in medicine. Acetylsalicylic acid, for example, is used for self-drugging more extensively than any other substance in the *Pharmacopœia*, if we except alcohol and caffeine. Again, the importance of rheumatic fever as one of the chief causes of permanent heart injury can scarcely be overestimated, and the salicylates are still our chief remedy in this disease. Finally, chronic muscular rheumatism is one of the commonest causes of partial disability, and here again the salicylates are the chief palliatives we possess. The real importance of these drugs in this last connexion was probably brought home to many during the first years of the war, when the supply ran short and regimental medical officers had to face sick parades with scarcely any salicylates available.

Dr. P. J. Hanzlik, Professor of Pharmacology, Stanford University, California, has recently published a monograph[1] on the action and uses of the salicylates and cinchophen in medicine, which is of particular interest because he has himself carried out extensive researches on the subject and can base his judgements on first-hand knowledge. Cinchophen, which is best known in this country by trade names, such as agotan or atophan, shows close affinities to the salicylates in its pharmacological actions, and although its most specific action is its power to increase the excretion of uric acid, yet its effect in relieving chronic rheumatism is important and perhaps more generally useful. Professor Hanzlik has collected all the evidence available, and a bibliography of some eight hundred references bears testimony to his industry. Nevertheless the outstanding impression left after a study of all he has to tell us is that our ignorance regarding the mode of action of this important group of drugs is still astonishingly great. This ignorance involves problems of both practical and theoretical importance. For example, clinical workers are almost unanimous in their opinion that the administration of sodium bicarbonate with full doses of salicylates lessens the toxic action of the latter; but apparently most of the controlled observations have failed to confirm this opinion, and Professor Hanzlik quotes an opinion to the effect that this practice rests on tradition rather than on reason. Similarly, the action of salicylates in relieving the symptoms of rheumatic fever is one of the most striking therapeutic effects seen in a hospital ward, and yet we know really nothing of the means by which this effect is produced. Hanzlik is emphatic that it is not a specific action, and concludes: "Hence, it appears that the relief of rheumatic fever by salicyl and cinchophen is mediated through the antipyresis and analgesia produced by these agents, which act rather efficiently, permitting

[1] *Action and Uses of the Salicylates and Cinchophen in Medicine.* By P. J. Hanzlik, M.D. Medicine Monographs, Vol. IX. London: Baillière, Tindall and Cox; Baltimore: The Williams and Wilkins Company. 1927. (Med. 8vo, pp. 290; 12 figures. 16s. net.)

comfort and rest while the joint symptoms disappear spontaneously and gradually."

Probably these conclusions will be doubted by many clinicians, but even if they are accepted they do not carry us very far, because we do not know the mode in which these drugs exert their antipyretic and analgesic actions. Barbour has advanced the theory that these effects are secondary to blood dilution, but Hanzlik appears to doubt the accuracy of this conclusion.

Since uncertainty exists regarding the most obvious and definite actions of the salicylates, it is needless to say that our ignorance is even more complete regarding their less dramatic effects. Most of the important actions of salicylates unfortunately cannot be tested by animal experiments, and will have to be solved by the more difficult method of clinical observation. In spite of the extensive literature on the subject, nearly all the questions of prime importance are unsolved, and the mode of action of the salicylates still offers a very profitable field for clinical research. If Professor Hanzlik's summary of our current knowledge—or rather, perhaps, of our current [illegible] the mode of action of these drug[s] investigation it will have served a very useful purpose.

INTERNATIONAL ANATOMICAL CONGRESS, LONDON.

ON April 11th, 12th, and 13th the Association des Anatomistes held its annual meeting, under the presidency of Professor Brachet, conjointly with that of the Anatomical Society of Great Britain and Ireland, under the presidency of Professor Elliot Smith, at University College, London. This is the first occasion on which such a meeting has been held in England, and it attracted a large gathering of anatomists from France, Belgium, Holland, Spain, Portugal, Italy, Switzerland, Poland, and Czecho-Slovakia, as well as from most of the British medical schools. There was a very full programme of communications and demonstrations, and the discussions were marked by a zest and geniality that revealed the deep interest in anatomical research and the reality of the anatomists' *entente*. Professor J. T. Wilson showed preparations suggesting that maternal haemopoiesis took place in the placenta. Some of the famous early embryos of man and other vertebrates were shown by Professors J. P. Hill, Teacher, and Bryce, and several others. A large part of the programme was devoted to cytology, the constitution of the cell, the processes of oogenesis and spermatogenesis, and fertilization, a remarkable demonstration by Professor Dalcq of Brussels of the processes of fertilization in the frog's egg, and Professor Parat's (Paris) account of the respective roles of mitochondria, the Golgi apparatus, and lipoids in oogenesis, arousing special interest and lively discussion. The Golgi apparatus in particular seemed to provoke the sharpest differences of opinion amongst those who specialize in that elusive study. Several communications were devoted to the sympathetic nervous system, of which the most noteworthy was Dr. Woollard's beautiful demonstration (by means of the methylene blue stain) of the existence in the striated muscles of mammals and birds of the two sharply contrasted types of muscle fibres and nerve endings to which the late Professor Kulchitsky called attention in reptiles (BRITISH MEDICAL JOURNAL, February 7th, 1925, p. 340)—that is, the existence of very fine muscle fibres innervated by non-medullated nerve fibres ending epilemmally in numerous grape-like terminations, sharply contrasted with the hypolemmal end-plates of the medullated fibres in the coarser muscle fibres. Professor Veuwiller (Zürich) gave a very startling exhibition of the internal structure of living plants and animals as revealed by a modification of the ophthalmologist's slit-lamp. But the communications were so many and so varied that it is impossible to summarize them. The meeting has demonstrated how much more living the subject of anatomy is becoming, and revealed the vital interest that anatomists are taking in the new vision of their subject which improved optical devices, radiology, and experimental methods are providing. During the meeting a conversazione was held at University College, at which demonstrations of x-ray cinematography, and a series of anthropological, histological, and embryological specimens of exceptional interest were shown, including microphotographs of Mr. Thorton Carter's sections of the enamel of a variety of vertebrate teeth, Professor J. P. Hill's early embryos of monotremes, marsupials, and of the rabbit, microphotographs of the late Professor Kulchitsky's exquisite preparations of the nerve endings in muscles, and Dr. H. A. Harris's radiological demonstration of the records in the bones of living people of their life-histories—the lines due to cessation of growth caused by illness or malnutrition. A reception was held at the Wellcome Historical Medical Museum. The Zoological Society also gave the visitors the opportunity of visiting its gardens and aquarium. On April 13th the members of the congress dined at King's College, and were honoured by the presence of the French Ambassador. On April 14th the foreign visitors go to Cambridge as Professor Wilson's guests.

THE LISTER CENTENARY IN LONDON.

NOT much remains to be added to the very full account of the Lister centenary celebrations in London published last week. We then mentioned that the Royal College of Surgeons of England gave a conversazione on the afternoon of April 5th, which was very largely attended; but the hospitality of the College did not quite end here, for on the evening of April 7th the President and Lady Moynihan gave a dinner in the library of the College. The occasion was remarkable, if not unprecedented, as the guests included ladies and men in about equal numbers. The guests sat at a number of round tables, and the proceedings were of an intimate and informal character. The chief guests were the Prime Minister and Mrs. Baldwin, but we will not attempt to enumerate the many other distinguished persons who were present. Sir Berkeley Moynihan gave the toast of "The King," but no speeches were made, and the guests were liberated early to inspect the collection of personal mementos of Lord Lister and of instruments and scientific apparatus used by him, of which some account was given last week (p. 675), as well as the more familiar objects always displayed in the various rooms of the museum. On the same evening a large number of guests were received at the Wellcome Historical Medical Museum, when Sir W. Watson Cheyne, who was in the chair, demonstrated some of the apparatus Lister used in his bacteriological investigations, as described and illustrated in these columns last week. Sir Watson Cheyne mentioned some of the difficulties Lister encountered in his pioneer work and the way in which he overcame them, and concluded by a reference to Lady Lister, who had been Lister's devoted helpmeet and amanuensis; they had been everything to one another, and her death was a crushing blow to him. Professor Archibald Young, Regius Professor of Surgery in the University of Glasgow, said that he spoke as the substitute for Sir Hector Cameron, who was to have represented the University, and whose long and faithful service to the master and to his memory would have rendered him peculiarly fitted for that duty on this occasion. The collection formed in the museum by the enterprise of Mr. Wellcome well illustrated the progress of Lister's ideas and the evolution of his method, and made it possible to study them in a way which neither oral narration nor written

description could permit. Professor Young quoted figures showing the mortality of major operations in the Glasgow Royal Infirmary in 1825, 1853, and 1925, which showed the comparative infrequency of that confession of failure, amputation, since the introduction of antiseptic surgery. Glasgow was proud of the fact that in the wards of its infirmary Lister elaborated his system and brought it to the test, which it so triumphantly stood. Sir William Macewen, the speaker's predecessor in the chair of surgery, was one of Lister's students, and carried some of his principles of surgery further than Lister had done. Indeed, it might be said of him that he was "Ipso Listero Listerior." The Glasgow students' hearts and heads were quickly won by Lister, for when, after one year in Glasgow, he became a candidate for the post of surgeon to the Infirmary, they took the very unusual course of drawing up a petition to the managers in his favour. This petition, which was on view in the Wellcome Museum, was signed by 161 out of 180 students. Lister always referred warmly and gratefully to the support he had from his students, and also to that of his father-in-law, Syme. Sir StClair Thomson said that Lister's personality had a good effect on his neighbours, who could not feel mean or do a mean thing in his presence. His gentle patience and sweet reasonableness won over adversaries—such, for instance, as Bryant and John Wood—and made of them friends and supporters. Much had been heard during the week of Lister's virtues. He had tried to think of his weaknesses, but all he could mention were his unpunctuality, mentioned by his nephew Sir Rickman Godlee, and another, often falsely attributed to Scotsmen, though Lister was not a Scot, that he "joked wi' deefficulty." Lister never felt the pinch of penury, and so was able to devote many years to the training and education of his own mind. He was not a success as a consultant, partly because of his uncommercial attitude to the question of fees, and partly because his personal devotion to the details of dressing wounds was apt to remove the case from the hands of the general practitioner. But his was a detached and lofty soul. Sir John Samuel of Glasgow proposed a vote of thanks to the speakers, which was seconded by Pasteur's grandson, Dr. Pasteur Vallery-Radot of Paris, who, in an excellent speech in French, recalled the cordial relations which existed between Pasteur and Lister and the interdependence of their work. If Lister depended on Pasteur, Pasteur in his turn also depended on another Englishman—Jenner. On the suggestion of Sir StClair Thomson, a telegram of thanks for his hospitality was sent to Mr. Henry Wellcome.

IMHOTEP: THE PHYSICIAN-ARCHITECT.

INTEREST in the contribution made by ancient Egypt to the history of medicine has been greatly stimulated by the light recently thrown on the life and achievements of Imhotep, the famous architect and physician of King Zoser, who reigned about 2980 B.C. Imhotep has long been recognized as the builder of the earliest pyramid—the Step-Pyramid at Sakkarah, not far from Cairo. During the last two years, however, extensive clearances and excavations at the base of this pyramid, directed by Mr. C. M. Firth, have brought to light some remarkable temple buildings which were also constructed by Imhotep, probably at the same time as the pyramid. Amongst these discoveries is a beautiful colonnade eighty-five yards long, composed of forty-eight columns of white limestone arranged in pairs and forming the main approach to the pyramid enclosure. These columns are fluted, and carry remarkable foliage and papyrus capitals, thus revealing an architectural style which archaeologists had not previously met with until a thousand years later. There are also halls finely decorated with blue tiles and exhibiting curious false doors, each ornamented with portraits of King Zoser in different costumes and attitudes. Even more recent than the discovery of these extensive temple buildings is the finding of a mastaba or grave close to the Step-Pyramid, which it is suggested may perhaps be the actual tomb of Imhotep himself, of the great architect and physician who so impressed his fellow countrymen with his skill as a healer of disease that after his death he was raised first of all to the status of medical demigod, and subsequently to that of full deity of medicine. Whether this surmise is true time only will show, but if the adscription should prove to be correct an interesting chapter could be added to the history of Imhotep which has recently been told us by Dr. J. B. Hurry in his illustrated volume published by the Clarendon Press, and reviewed in our columns on October 16th, 1926 (p. 692). Owing to the climatic conditions of Egypt, further excavations must be postponed until next winter, when possibly important revelations bearing on the early history of medicine may be forthcoming. Already, however, enough is known of Imhotep, "the first figure of a physician to stand out clearly from the mists of antiquity," to raise the question whether he, a man of flesh and blood, should not be substituted for his younger and semi-mythical rival Asklepios as the patron deity of medicine.

PRISON PSYCHOSES.

THE morbid mental states included in the category of prison psychoses have been well discussed by Dr. H. T. P. Young, medical officer to H.M. Convict Prison, Parkhurst, in a recent issue of the *Journal of Mental Science*. He defines prison psychoses as special types of mental reactions developing upon conflicts which arise as the result of imprisonment, and possibly from the shock attending the criminal act, trial, and conviction. Among approximately 300 convicts placed under medical observation at Parkhurst recently, disordered states of the prison type were observed in 19. The mental condition in these cases resembles Kraepelin's mild form of paranoia of psychogenic origin. The delusions manifested are of a combined grandiose and persecutory type, based, as a rule, upon a belief in their own innocence and wrongful conviction, and are directed towards police and prison officials. This type of disorder is most commonly met with in recidivists, whose recurring convictions give them a familiarity with police and penal methods. The symptoms do not as a rule develop rapidly; usually a period of six to eighteen months is required. In first offenders the psychosis tends to assume the features of an anxiety neurosis of traumatic origin, and in recidivists that of systematized delusional insanity. As might be expected, the symptoms frequently disappear when the prisoner regains his freedom—that is to say, when he is removed from the traumatic situation which has provoked them. It should be understood that at Parkhurst are concentrated all those convicts whose mental state, at any time subsequent to arrest, has given rise to doubt as to their fitness for ordinary convict conditions. It is thus evident that the proportion of psychoses in convicts which is attributable to the specific effects of the prison environment is small (19 in 300). No doubt the improved conditions under which convicts are now dealt with are responsible for the diminished incidence of the "prison psychoses." Dr. Young is of opinion that impaired health, often due to chronic focal infections, is one of the factors which favour the development of a prison psychosis. An impairment of health appears to exert a definite influence on the minds of certain persons, leading to the production of those fantastic conceptions through which a failure of adaptation may be diverted from reality. Monotonous occupations are also liable to stimulate the tendency to fantasy formation, and Dr. Young states that since the character of prison labour has been altered there has been a diminu-

tion in the intensity and frequency of the prison psychoses. Convicts who are compelled, by reason of some physical defect, to work at the less productive or interesting tasks are, on the whole, more liable to develop morbid states of mind than those whose tasks more closely approximate to the work to which their class is accustomed outside prison. This clinical study has naturally a particular interest for those concerned with the care of convicts who exhibit mental disturbances. It should enable them to seek out and remedy as far as possible those features in the prison environment which appear to be instrumental in the production of psychotic symptoms. The study also has a general psychiatric interest. The prison psychosis would appear to belong to the category of cases to which the terms "psychogenetic," "situation," or "reaction" psychoses have been applied. Instances were sometimes observed in soldiers about to proceed to the front (anticipation psychoses) or who had been in action, and they also occur in civil life in prisoners awaiting trial, or in persons faced with situations calculated to provoke a profound emotional upset—such, for instance, as the discovery of a condition of pregnancy in an unmarried woman. In such cases, where the psychic trauma is sudden and intense, rather than prolonged and insidious as in the prison psychoses, the symptoms take the form of confusion and stupor, or of a "wish-fulfilment" delirium. It is not to be wondered at that individuals faced with situations which threaten their life, involve them in social disgrace or the loss of their liberty, should manifest psychotic symptoms; rather is it surprising that relatively few of them do so. The fact that the incidence of such cases is comparatively small makes it evident that the most important causal factors in the psychoses as a whole are not to be discovered in external circumstances, but in defects of the personality or in morbid states of the organism.

MILD SMALL-POX ON SHIPBOARD.

On February 25th, 1926, a steamer sailed from London for Sydney, New South Wales, with a complement of 1,203 souls, being 231 of a crew and 972 one-class passengers, mainly emigrants. She touched at Las Palmas, Capetown, Adelaide, and Melbourne, and reached Sydney on May 3rd. On her arrival at Adelaide on April 10th the quarantine officer picked out four missed cases of mild small-pox (alastrim) from the muster of her passengers. At Melbourne two more missed cases were found, and six fresh ones developed. Two further cases, which occurred among the passengers detained in quarantine at Adelaide, raised the total to fourteen. The original case of the outbreak was an English passenger from Consett, county Durham, where the disease had been epidemic. He sickened on March 6th, when ten days at sea, and was logged as suffering from bullae, but was not isolated. The second case, probably infected by the first in the eruptive stage, sickened on March 29th, and was logged as febricula. The third case, who sickened about the same time as the second, did not report sick. The fourth case, who sickened on April 1st, was logged as catarrh and pustular eruption. Two further cases on April 5th complete the number infected from the first case. The remaining group of eight cases sickened from April 13th to 23rd. The diagnosis of the early cases was complicated by the concurrent prevalence on the ship of influenza, measles, and impetigo contagiosa. Two cases occurred in one cabin; three in another; for the rest contact may be presumed. Of the fourteen cases, ten had never been vaccinated, and four had been vaccinated in infancy only. Infection followed the line of greatest opportunity of contact, and selected the unvaccinated to a significant degree. The control measures adopted included vaccination in terms of the Commonwealth Quarantine Act; 1,072 persons were vaccinated, 111 were exempted for cause shown, and 6 conscientious objectors were detained, prosecuted, and fined. The work was got through by one operator at the rate of 100 vaccinations an hour. The methods adopted were: for 90 of the crew scarification, for 150 passengers linear incision, and for the rest acupuncture. The results were uniformly successful. This outbreak of alastrim, which is of interest as occurring in a closed community, is described in a recent report of the Commonwealth Department of Health. The report presents also a review of the results of the vaccinations carried out on persons previously unvaccinated and vaccinated once and twice or oftener, at various age-periods, with respect to the occurrence of the immunity reaction, the accelerated reaction in its two grades, and the typical Jennerian reaction. The protection afforded by previous vaccinations was observed to decrease with the lapse of time.

THE NATIONAL PHYSICAL LABORATORY.

THE report of the National Physical Laboratory at Teddington for the year 1926 is a bulky document, containing accounts of much experimental work in many branches of physics. Amongst matters with a medical interest it is noted that the number of clinical thermometers received for testing again shows a small fall, and that a specially designed x-ray equipment is in use for distinguishing different kinds of glass used for the stems of the thermometers. It has been found that the only satisfactory measurement of x-ray intensity and dosage involves the use of an ionization chamber. Amongst the hospitals inspected to fulfil the recommendations of the X-Ray and Radium Protection Committee, the report makes special mention of the new radiological department of the Edinburgh Royal Infirmary as the largest and most up-to-date x-ray department attached to any hospital in this country, or probably elsewhere. It is proposed to use photo-electric methods of spectrophotometry in measurements of ultra-violet light. Work for the Dental Investigation Committee has been continued at the laboratory for the purpose of throwing further light on the phenomena of dental amalgams, and the ageing phenomena in silver-tin alloys and certain analogous alloys of gold. The bulk of the report is concerned with researches in aerodynamics, metallurgy, electricity, and metrology.

POST-GRADUATE TOUR TO AMERICA.

FURTHER details are now available with regard to the post-graduate tour in Canada and the United States of America which is being arranged by the Section of Surgery of the Royal Society of Medicine. Starting from Southampton on August 20th, Quebec will be reached on August 28th, and the following towns will be visited; Montreal, Ottawa, Toronto, Chicago, Rochester, Grand Rapids, Ann Arbor, Detroit, Cleveland, Washington, Baltimore, Philadelphia, New York, and Boston. On the return journey the party will sail from New York on September 24th, Plymouth being reached on October 2nd. The estimated minimum cost of the tour is £138, together with about £25 for out-of-pocket expenses. Fellows of the society other than members of the Surgical Section can join the tour on being nominated by the Tour Committee, but members of the medical profession who are not Fellows of the society, and who wish to accompany the party, must be nominated by two members of the Surgical Section. All those who wish to participate must pay a deposit of £6 on or before May 1st, after which date reservations cannot be guaranteed. Full details may be obtained from Mr. C. Max Page, 134, Harley Street, W.1.

AT a statutory meeting of the Royal College of Physicians of London on April 11th, Sir John Rose Bradford was re-elected President for the ensuing year.

Nova et Vetera.

THE BLACK DEATH.

FEW will fail to admit the fascination exercised by even a second or third hand account of a great pestilence. "Fear," says a character in one of Stevenson's tales, "is the strong passion; it is with fear that you must trifle if you wish to taste the intensest joys of living." It is the dramatization of fear in its grimmest form, panic fear, that we discover in any good account, above all in a contemporary account, of a great pestilence. One wonders whether, if the great pestilence of our own day had not come upon a Western world whose emotions of fear had already been stimulated almost to the point of exhaustion, there might not have been a strange contemporary story to record of panic and horror.

The great pestilence of 1348-50 has been well described by several modern authors; two of the best accounts, those of Cardinal Gasquet and Dr. Charles Creighton, were originally written in English, while Hecker's story—uncritical, indeed, but learned and well written—has long been available to English readers in translation. To those who can read German, Heinrich Haeser's account (in the third volume of his *Lehrbuch der Geschichte der Medicin*, a book which, whether in point of scholarship or literary charm, has seldom been surpassed) can be recommended as never likely to be improved upon. All these writers—especially Haeser, who gives a very useful collection of the most important records—quote eye-witnesses copiously, but they did not confine themselves to the compilation of such records nor seek to be exhaustive in this respect. Further, the most recent of the books quoted was published more than thirty years ago; since then a certain amount of important historical information has been brought to light, while the reappearance of bubonic plague on a large scale in countries accessible to scientific investigation has led to discoveries completely revolutionizing our doctrines of the epidemiology of the disease.

The author of the book which has recently appeared in an English translation with the title *The Black Death: A Chronicle of the Plague*[1] has profited by the former but very little by the latter additions to knowledge. We do not know whether Johannes Nohl is a medical man, and, it is not always easy to distinguish between his own views and those of his authorities, but there are some passages—for example, on pp. 112-113—which suggest that his acquaintance with modern work is rather superficial. Even from the historical point of view, the book is open to criticism. It is a little disconcerting to find, at the beginning of the first chapter, the unqualified assertion that "The name 'Black Death,' which was commonly given to the plague of 1348, must be regarded as the expression of the horror aroused by this uncanny disease. Popular imagination depicted it as a man mounted on a black horse, or else as a black giant striding along, his head reaching above the roofs of the houses." As a matter of fact, Gasquet pointed out that the name Black Death, *atra mors*, is not older than the seventeenth century. It is also strange to find Defoe's interesting fiction termed "a masterly history of the Plague of London in 1664 and 1665." Finally, although a bibliography is appended, it is impossible to connect passages, even when cited between inverted commas in the text, with the sources from which they come.

It would be unfair to judge the original by a translation, and we have not seen the original, but if the translator has done his author justice, we cannot say that Mr. Nohl is of the class, including Hecker, Haeser, Hirsch, and Sudhoff, which made Germany superior even to France in the field of medical-historical scholarship. Still, it would be unjust and ungrateful both to Mr. Nohl and his translator not to say that this book does bring together in a convenient form a great deal of painfully interesting information. Many examples are given of the horrors of the persecutions of the Jews, and a graphic account of the experience of Suso, a South German mystic, sent on the business of his convent with a half-witted servant into Alsace in 1348. The idiot's foolish talk aroused suspicion that he was one of the well-poisoners; he was haled before the provost, and to save himself asserted that his master (who was carrying a mail bag) was the culprit. Suso, on returning to his inn, hearing that his servant had been arrested but nothing of the rumour, hurried to the provost, secured his servant's release, and was then set upon by a howling mob, from whom he escaped with his bare life. In Rostock, a priest who had been tending the sick was suspected of plague-making. He was imprisoned, bound and gagged, for twenty-six weeks, and tortured in various ways. When, ultimately, he was acquitted he was required to swear that he would make no complaints of his treatment. The torturing to death of a barber in Milan, not in the Middle Ages but on July 17th, 1630, is a hideous story. This man and a commissioner of the health office were thus treated.

> "First they were placed upon a cart and driven to the place of execution. On the way they were pinched with glowing tongs at every place where poison had been smeared; before Mora's house they both had their right hands cut off, and subsequently they were both broken on the wheel, being placed living on the wheel and strangled after six hours, their corpses were burnt with fire, their ashes strewn upon the water, Mora's dwelling was pulled down and in its place a column of disgrace was erected with the following inscription:
>
> "'On this spot stood the barber's shop of John Jacob Mora, who conspired, together with William Platea, an official of the public health offices, during an epidemic of plague, by smearing mortal ointments to contrive the cruel death of many.'"

Long after, this document, dictated to a confessor, was published:

> "In the name of Jesus, the 31st July, 1630,[2] I, Jacobus Mora, barber, enter protest against my sentence to death and, as I do not wish to leave this world with a weight upon my conscience, I once more protest and declare in this document that all who in the course of this trial were accused by me to have been concerned in the manipulation of pestilential ointments are completely innocent. I write this in the presence of the Capuchin fathers and witnesses for the salvation of my soul."

Such instances are examples of the purely horrible effects of fear. Of the grotesquely horrible atmosphere of plague times an instance may be given. It is from Regensburg, apparently at the end of the seventeenth century.

> "A street-sweeper of the name of Zacherl was appointed gravedigger at the pest house; he was at constant loggerheads with the cook. When the latter died of the plague he laid her over his shoulder and carried her to the plague burying ground; he stripped her naked of her clothes and, as he only found one single small coin on her, he tore a strip from her chemise, rolled it up like a sausage and inserted it in her uterus,[3] the coin he thrust into her nostril, and, hurling her into the trench, he said: 'Lie there, you beast; you never would cook me a good soup.'"

These are neither the most gruesome nor the most grotesque stories in the book. Perhaps for grotesqueness we should give the palm to remedies against plague, often prescribed by members of our faculty. "A wash with urine," says one pundit, "does more than any other preventive, more particularly when, in addition, the urine was drunk." We, however, have no sure remedies against pestilence, and probably we too should come under the empire of fear if such a mortality as that of 1348-50 were pandemic. But it is reasonable to believe that our fear would not find such horrible methods of expression as it found in civilized societies even much later than the reign of Edward III.

THERAPEUTIC SUBSTANCES ACT.

ISSUE OF DRAFT REGULATIONS.

THE aim of the Therapeutic Substances Act, which became law on August 7th, 1925, is to provide for effective control of the quality and the authenticity of such therapeutic substances as cannot be adequately tested by direct chemical means. This it seeks to do by regulating their manufacture, testing, sale, and importation. Substances of this kind fall into three categories. The first includes such biological preparations as vaccines, serums, toxins and antitoxins and antigens; the second, the group of synthetic products comprising salvarsan and its analogues; and the third consists of insulin and preparations of the pituitary gland intended for use by injection.

An article summarizing the main provisions of the Act, and describing the circumstances that led to the placing of this much-needed measure on the Statute Book, appeared in the SUPPLEMENT of September 12th, 1925, p. 105. The Act, which applies to England, Scotland, and Northern Ireland, declares that the manufacture of the scheduled substances is to be conducted only by persons and on premises specially licensed for the purpose, and under conditions laid down by the Licensing Authority, such authority being: for England, the Minister of Health; for Scotland, the Secretary of State for Scotland; and for Northern Ireland, the Minister for Home Affairs. The duty of defining standards, and thus securing uniformity, was entrusted to a Joint Committee consisting of the three authorities named, or their deputies, and acting after consultation with an expert advisory committee. The advisory committee consisted of Sir George Newman (chairman), representing the Ministry of Health; Mr. John Jeffrey, Scottish Board of Health; Sir Thomas Houston, the Ministry of Home Affairs in Northern Ireland; Dr. H. H. Dale, Medical Research Council; Sir Nestor Tirard, General Medical Council; Dr. C. O. Hawthorne, British Medical Association; Dr. J. H. Burn, Pharmaceutical Society of Great Britain; and Dr. J. F. Tocher, Institute of Chemistry.

The Joint Committee was empowered, after consultation with its advisory committee, to make Regulations prescribing the standard of strength, quality, and purity of any substances to which the Act applies, the tests to be used to determine whether that standard has been attained, the units of standardization to be employed, the form of the licences, and the conditions of their issue. The Joint Committee may also, by regulation, add to the schedule of the Act any therapeutic substance whose purity or potency cannot be adequately tested by purely chemical means. All imports must be consigned to a person duly licensed, and must satisfy the authority that they comply with the standards in force for the home products. The application of the Act was restricted in three directions. Medical practitioners were left free to prepare any of these substances for the use of an individual patient; special licences to import were to be issuable to persons engaged in research, such licences allowing the import for experimental purposes of substances not complying with the standards laid down; and power was given to the Joint Committee to exclude from the application of the Act substances intended for veterinary use alone. Lastly, the Act prescribed that the Regulations made under it should be laid before both Houses of Parliament and subject to modification or annulment under the ordinary procedure on presentation of an address by either House.

The Therapeutic Substances Regulations, 1927.

The Joint Committee, after consultation with the advisory committee, has now issued draft Regulations,[1] to come into force on August 6th next. These prescribe the conditions under which licences will be issued for manufacture and importation, and deal in detail with standards of strength, quality, and purity and with such matters as containers, labels, and so forth. The work incidental to the determination of the required standards has been carried out by the Medical Research Council or under its direction.

Part I of the Regulations is concerned with their interpretation, etc. Part II governs the issue of licences to manufacturers, and specifies the general conditions to which every licensee shall be subject, in addition to the special conditions, if any, set out in the relative schedule. These general conditions relate to the provision of adequate staff, premises, and plant for testing strength, quality, and purity, including proper housing for animals used for such tests; to the keeping of permanent records of the details of manufacture of each batch and its testing; to the provision of facilities for inspection of premises, plant, and processes of manufacture and testing; and to the furnishing of samples. Where a licensee contravenes or fails to comply with some condition of his manufacturer's licence, or with any of the Regulations, but not so as to justify its revocation or suspension, the Licensing Authority may compel him to submit a sample of every batch of the substance, and forbid him to sell or offer for sale any batch without a certificate authorizing him to do so.

Part III directs *inter alia* that if any of these therapeutic substances is advertised or sold as a proprietary medicine the "proper name" of the substance as given in the schedule must appear on the label. The sale of any substance after the date stated on its container is forbidden, except where a medical practitioner, being aware of the date, is satisfied that the sale is required by the urgency of the case. No substance is to be sold except in sterilized glass containers adequately sealed, and stringent conditions are laid down regarding the particulars to be entered on labels. Part IV is concerned with standards of strength, quality, and purity, and with tests for determining whether these standards have been attained. Such standards and tests are specified in the relative schedules. Detailed instructions are given regarding tests for the presence of living aerobic or anaerobic bacteria, the procedure to be adopted if a growth of micro-organisms is visible at such examinations, and the testing of substances, by inoculation into mouse and guinea-pig, for freedom from abnormal toxicity.

Part V lays down the conditions to be observed by persons licensed to import therapeutic substances for purposes other than those of scientific research, and Part VI deals with research licences. Part VII exempts from the application of the Act and Regulations any therapeutic substance labelled "to be used solely for veterinary purposes" and intended to be so used.

Schedules to the Regulations.

The first schedule sets out forms of application and forms of licence for the manufacture and import of therapeutic substances.

The second schedule sets out the provisions applicable to (1) the production of bacterial vaccines and vaccine lymph; (2) the reagents used in the Schick test, and the testing of diphtheria prophylactic; (3) tuberculin and other preparations from *B. tuberculosis* and its cultures; (4) the production of all serums from living animals, and of particular serums and antitoxins. The special provisions apply respectively to antimeningococcal serum and other serums for which no potency test is prescribed, to antidysentery serum (Shiga) and other antidysentery serums, to diphtheria antitoxin, and to tetanus antitoxin.

The third schedule sets out general provisions applicable to salvarsan and its derivatives, together with special provisions applicable respectively to salvarsan, neosalvarsan, sulphuro-salvarsan, silver-salvarsan, neo-silver-salvarsan, and to derivatives of salvarsan other than those specified.

The fourth schedule lays down the conditions required in respect of insulin, which is defined as "the preparation of the specific antidiabetic principle of the pancreas"; and the fifth schedule deals in corresponding terms with pituitary (posterior lobe) extract, defined as "the watery extract prepared from the separated posterior lobe of the pituitary body."

THE SCIENTIFIC SECTIONS.

COMBINED MEETINGS.

Treatment of Crippling Due to War and Industry.

THE subject of crippling resulting from war and industry was considered by a combined meeting of the Sections of Naval and Military Medicine and Orthopaedics.

Dr. H. S. NEWLAND (South Australia), opening the discussion, said that prior to the last war orthopaedics had not been linked in any way with military surgery. During the first eighteen months of the war it became evident that soldiers with certain types of injury needed special treatment, and hospital accommodation was reserved for them; a little later on the need for the establishment of orthopaedic hospitals became urgent. At first about 250 beds had been provided, but by the end of the war the number of these had increased to 30,000. A considerable amount of preventive work was possible, and the orthopaedic service of an army should ensure the exclusion from the combatant forces of men with certain forms of physical unfitness; many of the remediable conditions could be treated before enlistment. During the battle period the orthopaedic service should maintain the efficiency of the men, both at the base and also with the advanced units. Excision of the contaminated tissue surrounding wounds had been the most important measure for preventing deformities, but it must be early in order to prevent sepsis, which was the chief cause of deformity and loss of function. Shock and haemorrhage had, therefore, to be promptly and efficiently treated, tourniquets being avoided as far as possible, and bandages applied with very great care. Foreign bodies and fragments of bone should be removed before the soldier was transferred to the base. The use of the Thomas splint had produced better results in the healing of fractures and in the alleviation of pain during transport. Before its employment became general the mortality among men with fractured thigh bones in the casualty clearing stations alone had been nearly 50 per cent.; this had been reduced to 15.6 per cent. Amputation of the limbs had been necessary in only 17.2 per cent. of the wounded as the result of skilled orthopaedic treatment of the soldier at the base, and subsequent shortening of the limb after fracture of the thigh had been diminished to a surprising extent.

Dr. R. B. WADE (New South Wales) dealt chiefly with treatment of the crippled soldiers in civil life, and spoke in high terms of the value of the work of Sir Robert Jones and Mr. Hugh Owen Thomas. Considerable difficulty in stimulating interest in the treatment of war cripples had arisen from the lack of accurate figures of the numbers in the community handicapped in this way. According to American statistics—which provided the most accurate figures at present available—there were 6 cripples per 1,000 of the population, 30 per cent. being less than 21 years old; 74 per cent. of these were under 6 years old, 18 per cent. between the ages of 6 and 14, and 7 per cent. between the ages of 15 and 19. Crippling was due to disease in 69 per cent. and to accident in 4 per cent., while deformity was congenital in 25 per cent. Infantile paralysis and spastic paralysis were responsible for 67 per cent. of the deformities. Dr. Wade thought that the American figures were approximately correct for Australasia, and it would therefore follow that there were in New Zealand about 9,000 cripples, of whom 3,000 were under the age of 21. In Australia there would be 36,000, including 12,000 under 21 years old. He believed that adequate surgical provision existed, but no means were available for education or vocational training. Since the illness usually occurred early in life and lasted through the main school years, the majority of these children were at the best only partially educated. The speaker pleaded that orthopaedic surgeons should therefore unite in a campaign for educating public opinion. Although it was the function of the State to tackle this problem, there seemed to be no hope of State intervention until public opinion had been stimulated by voluntary organizations. He recommended, therefore, the provision of adequate orthopaedic treatment, district visitors being employed to encourage patients to take advantage of it. Educational training should be established for children in hospitals or attending as out-patients, while special accommodation for crippled children should be attached to general schools. Convalescent homes and vocational schools were also required, and arrangements should be made by unions and arbitration bodies whereby a worker, slow through crippling, should be enabled to obtain a living. Legislation should be introduced to enable the State to provide money for surgical treatment and education.

Parasitology in the Tropics.

Hookworm, trematode infections, and yaws were discussed by a combined meeting of the Sections of Pathology and Preventive Medicine.

Dr. T. R. RITCHIE (Samoa) opened with an account of the control of hookworm in a native community. He said that in 1923 a campaign against this parasite had been begun in Samoa based on the work of the Rockefeller Foundation. Each night a lecture was given on the village green, with lantern slides or portable cinema, and early next morning the whole population was dealt with, mass treatment being given as over 90 per cent. of the population harboured the parasite. Systematic treatment had been continued since 1923, everyone being given the opportunity of having treatment at least once a year. A vigorous educational policy had been pursued, special attempts being made to interest the women; committees were formed and duties were assigned to them. An article on hygiene was supplied to every issue of the school journal. The question of the type of latrines had been difficult. At first drop latrines over the sea and pit privies in inland villages had been built; these were being, or would be, replaced by water-carriage systems where piped water supplies became available. In mass treatments they used a mixture of carbon tetrachloride three parts, and oil of chenopodium one part, the dose being 0.12 mils. (2 minims) per year of age, with a maximum dose of 2 mils. (35 minims). This combination removed *Ascaris lumbricoides* as well as hookworm.

Dr. G. A. M. HEYDON (Queensland) dealt with the influence in hookworm infection of the species of worm and of the race of man, and on the characters of the larvae as a means of determining the species distribution. He said he had been much impressed by the elusiveness of hookworm disease in New Guinea. The clinical signs and symptoms were conspicuous by their absence, and it was impossible to determine from these whether a patient had a thousand worms or only a few. In North Queensland the picture was different. The infection rate was far lower, but several cases of severe hookworm disease with advanced anaemia had been investigated in white adults. The cases of serious disease seen so far had been caused by *Ancylostoma duodenale*. The worm count method was the only available way of finding out the species distribution of hookworms in a country. Many practical difficulties arose in a white community, and this procedure could not be applied on a large scale even to native races. He gave a detailed account of a method of examination of larvae from faecal cultures. He emphasized the fact that the two species of human hookworms had not the same pathogenic importance; there was great need to determine the prevalence and distribution of each.

Dr. R. W. CILENTO (New Guinea) discussed trematode infestations in Northern Melanesia. He said that last year paragonimiasis had been discovered in a native recruited from a distant and rarely visited native village. The disease was dangerous, and as the patient had never been away from his village in his life previously there must be effective intermediary hosts for paragonimiasis in New Guinea. This was the first case found in the Pacific anywhere south of the equator. The symptoms, pathology,

and transmission of the disease were detailed. In New Guinea the local molluscan genera had not been described in readily available papers, but it was obvious that some local species must be capable of transmitting the parasite. Dr. Cilento asked members of the Congress who were practising in the Polynesian Islands to endeavour to determine whether trematode infestations were locally present, so that measures might be introduced to combat what might otherwise become a menace.

Dr. T. R. RITCHIE (Samoa), introducing the subject of yaws, said that systematic work for the control of this condition in Samoa had been undertaken in 1923. The district to be treated was divided into areas which could be readily dealt with in five treatment days. Treatment was given at five selected points in the area with novarsenobillon, and on the sixth day the party retraced its steps to the point of commencement of treatment. Second and third injections were given at the same points during the second and third weeks; thus each case received three injections at weekly intervals. The majority of primary and secondary lesions cleared up with three injections. The administration was not particularly anxious to cure thoroughly every patient. As all adult Samoans had had yaws in their early youth, they were immune from further attack. To treat them thoroughly for tertiary yaws would be to withdraw that immunity, and so render them liable to contract the disease again. Until primary and secondary infections were reduced to a negligible number, the acquired immunity of the adult was better left alone. Meanwhile the children were growing up free of the condition. Cases of syphilis were not seen among Samoans, probably because yaws conferred some immunity to syphilis; to eradicate yaws completely might be dangerous until syphilis was under control.

Delinquency.

The Sections of Neurology and Preventive Medicine united in a discussion of various aspects of delinquency.

Dr. HARVEY SUTTON, dealing with delinquency in New South Wales, included truancy, because it was inseparable from the major problem. Every child that came before the children's court was given a complete medical examination, and it was found that all forms of physical defects were in excess, as compared with the usual finding in the child population. Defects of the nose, throat, and ear were especially prominent, and appeared to intensify maladjustment with the school and everyday life. Parental failure seemed to be the main factor in causing delinquency; industrialism with its overcrowding, poverty, and intemperance formed the background. At puberty a marked rise in minor offences occurred in boys, but in girls the rise was in serious offences—a secondary sex phenomenon shown by the relative frequency of gonorrhœa in girls. Feeble-mindedness was important as a causative factor, but should not be overestimated. Dr. Sutton then referred to the programme for the future, and pleaded for reorganization, so that every delinquent should be examined by a psychiatrist, a psychologist, and a social worker (probation officer).

Dr. S. J. MINOGUE (New South Wales) raised the question of crime and insanity, and divided insane criminals into congenital mental defectives and those with other forms of mental disease. In his experience about 50 per cent. of all insane criminals in New South Wales were mentally defective. Their detection was an urgent and much neglected necessity in Australia, and those discovered should be treated in colonies or mental hospitals. Among prisoners suffering from mental diseases other than mental deficiency he found generally that the crime committed was the direct result of the mental disease present. Very few criminals became insane while in prison. Dr. Minogue then discussed the moral imbecile and the victim of irresistible impulses, and the problem they presented in treatment. After referring to legal responsibility of the criminal insane and outlining the procedure adopted in New South Wales, he concluded with some remarks on the attempts now being made in America to reform prisoners by complete and thorough psychological examination and treatment.

Dr. ST. LEGER GRIBBEN (New Zealand) confined his remarks to the adult delinquent. He said that the importance of a knowledge of the offender's mental standing was being increasingly recognized; the International Prisons Congress in England last year had passed a resolution that every person convicted of a crime should be mentally examined before sentence was passed. Dr. Gribben considered that the three essentials for successfully dealing with a delinquent were classification, individualization, and a practical knowledge of the criminal mind and outlook. The question of criminal reform had been much before the public during recent years. The greatest incentive to a criminal to reform would be the realization that it would pay him to do so. He had had some experience of the "honour system," and the results had been highly encouraging; he felt sure that it would be extensively used in the near future. He concluded with a eulogy of those workers engaged in easing the way back to civil life of persons who had fallen under the ban of the law.

Dr. BUCKLEY-TURKINGTON said that medical tests had been performed on infirmary boys in South Australia, and many physical defects, especially of the nose and throat, had been found. In many cases sent by magistrates for medical examination physical defects were in great evidence. Dr. MOORE eulogized the work of Dr. Gribben in prison reform, and said that he had created an impression of discipline in the prison, any prisoner who wished to reform being now given every opportunity to do so.

Spastic Paralysis.

The Sections of Medicine, Neurology, Surgery, and Orthopaedics held a combined meeting for the discussion of spastic paralysis.

Dr. S. V. SEWELL (Victoria) first gave a brief review of the proprioceptive nervous system, outlining the three main pathways of afferent impulses originating in muscles, the first level arc, the second level tonus and posture maintaining arc, and the third, the plastis arc. He also mentioned the cerebellar-cerebral connexions, emphasizing the fronto-pontine fibres. Experimental investigations had shown that the spasticity due to lesions in the internal capsule was caused by the simultaneous involvement of these fronto-pontine fibres, and not by the involvement of the pyramidal tract. Conditions like paralysis agitans, post-encephalitic rigidity, and Wilson's disease were probably instances of disease destroying the inhibitory mechanism of the striate level. It was possible that tonus-maintaining impulses, associated with the maintenance of posture, initiated from the emotional or striate level, found their final common pathway by way of the sympathetic outflow to the muscles: this would account for the slight improvement reported after sympathectomy in cases of post-encephalitic rigidity.

Dr. N. D. ROYLE (New South Wales) gave a cinematographic demonstration on ramisectomy.

Dr. H. R. G. POATE (New South Wales) gave his personal experience of Royle's operation of sympathetic ramisection. He had had under his own immediate care twenty patients on whom the operation had been done, and he had seen many of Dr. Royle's patients both before and after the operation. After dealing with the indications for the operation, he reviewed the operative results, from the point of view both of the observer and of the patient, and gave figures showing that in the main they agreed. In no case was there a failure to obtain a physiological result. This was noticed by the patient immediately he recovered consciousness. The most noticeable post-operative feature in cases in which the lower limbs were affected was the restoration of balance. There was often also some amelioration of the obstinate constipation, and relief from chilblains. In his experience the best results had been obtained in cases of spasticity following cortical injury, and in an occasional case of post-encephalitic rigidity.

Osteitis Fibrosa and Osteitis Deformans.

Inflammations and tumours of bone were discussed by a combined meeting of the Sections of Pathology, Surgery, and Radiology.

Dr. H. R. SEAR (New South Wales) expressed the opinion that osteitis fibrosa and osteitis deformans merged into one another. One of the greatest difficulties that beset a radiographer was the absence of confirmation of many of his

diagnoses. Other workers had since reported cases showing apparently the two lesions in the same patient. He had seen well over two hundred patients, and thought that the lesion of osteitis deformans was much more common in Australia than in other countries. He reviewed a number of cases, and concluded that under the two headings of osteitis deformans and osteitis fibrosa they were dealing with one pathological entity. He considered that the radiological appearance of the skull did not assist in forming a diagnosis.

Various Neurological Subjects.

A combined meeting of the Sections of Neurology and Medicine was held to consider the sequels of encephalitis lethargica and the localization of spinal tumours. A cinematograph demonstration of the teaching of neurology was given by Dr. J. F. MACKEDDIE (Victoria).

Dr. H. F. MAUDSLEY, *M.C.* (Victoria), in a paper on the neurological aspects of the sequels of encephalitis lethargica, said that in the chronic form this disease affected the extrapyramidal motor system, and was generally progressive; Parkinsonism, its commonest form, was due to *lesions in the substantia nigra. The corpus striatum gave* a non-voluntary component to voluntary movements by tracts passing through the substantia nigra. If this were damaged the involuntary component was lost and bradykinesia, as, for instance, the loss of arm-swinging in walking, ensued. The cause of increased muscle tone was still debated, but increased sympathetic action seemed evident. Many other parts of the brain, such as the pyramidal tracts, the bulb, and the medulla, might be affected and show symptoms. There was no specific treatment, but rest and hygiene were useful, and hyoscine was a valuable drug; he had seen no good from ramisectomy.

Dr. W. MARSHALL MACDONALD (New Zealand) remarked that the disease was important, because it was now playing a considerable part in filling hospitals for chronic cases. The slow evolution of the original disease led to a multiplicity of lesions or sequels. The commonest sequel was Parkinsonism, the mask-like face of which was attributable to the retention of the voluntary with loss of the emotional or automatic movements. He described the physical signs and symptoms that might be elicited and the tests that might be performed. A list was given of the mental, or rather the moral, changes in children, and for these psychotherapy was of little use, but much might be achieved by careful parental control. The moral changes were of special interest to those occupied in medico-legal and pensions work. The forms of treatment were mentioned. He enumerated the resemblances between the mental sequels of lethargic encephalitis and the symptoms which occurred in the ordinary psychoneuroses. He suggested as a field for histological research a possible origin of the psychoneuroses in the excitations and inhibitions due to vascular changes in the mid-brain consequent on nasopharyngeal infections, fevers, or influenza.

Dr. J. F. MACKEDDIE (Victoria), discussing the localization of spinal tumours, said that the discovery of lipiodol with its special properties had rendered possible the exact localization of tumours of the spinal cord, and had thus limited surgical procedure to an exact field where formerly it had been undertaken in too exploratory a fashion. Lipiodol injected into the cisterna magna was held up by any compression area in the spinal cord. The indication for its injection was Froin's syndrome. The harmlessness of the preparation had been amply confirmed. The method of puncture of the cisterna magna was then described in detail. There followed a demonstration of *x*-ray photographs where lipiodol had been successfully used. Recent acquaintance with the new preparation, "lipiodol ascendens," had indicated the ease of its administration and its harmlessness.

Dr. J. RENFREW WHITE (New Zealand), continuing the discussion of the localization of tumours of the spinal cord, said that the non-neurological evidence was obtained by examination of the cerebro-spinal fluid and by radiography. The evidence obtained by lumbar puncture included Froin's syndrome, and measurement of the pressure of fluid in different regions by multiple punctures until the different pressures indicated the site of the block. The injection of substances into the subarachnoid space for radiographic purposes was valuable, but lipiodol had been known to become encysted, and its use was therefore not without danger. Pneumography, in which the cerebro-spinal fluid was replaced by air below the lesion, seemed to obviate this. Ordinary radiography would reveal exostoses, spinal tuberculosis, syphilis, and cancer. Compression from osteo-arthritis might simulate a tumour.

Dr. OLIVER LATHAM (New South Wales) contributed some observations on the examination of the cerebro-spinal fluid to a combined meeting of the Sections of Medicine and Radiology. He described the method of withdrawal and the necessary precautions, giving suggestions as to procedure in connexion with bacteriological and pathological diagnostic requirements. The naked-eye appearances which aroused suspicion of lethargic encephalitis, tuberculous meningitis, and other conditions were mentioned. Bacteriological examination entailed such practices as grouping the meningococci present. The cells should be counted soon after withdrawal. The procedure for investigating the organisms and the cytology was described and the results *correlated with the respective diseases. Emphasis was laid* on the value of testing for specific proteins in certain diseases, both qualitatively and quantitatively. The gold-sol test had been found eminently useful as being almost pathognostic of general paralysis. The value and applications of the Bordet-Wassermann test, the estimation of chlorides in suspected tuberculous meningitis, and the procedure for glucose and urea estimations were given with deductions. Use was made of a table of the clinical states, the tests used, and the reactions commonly found.

(To be continued.)

ROYAL MEDICAL BENEVOLENT FUND.

THE annual meeting of the Royal Medical Benevolent Fund was held in the rooms of the Medical Society of London on April 8th, with Sir THOMAS BARLOW, President of the Fund, in the chair.

Sir CHARTERS SYMONDS, the treasurer, in presenting the financial statement, said that the investments in the general annuity fund, apart from special named bequests, now stood at £96,205. The income derived from invested property during the year was £4,718, as against £4,550 the year before, and the income from subscriptions and donations £7,250, as against £6,685. An increased number of new subscriptions, accounting for £1,050, was noted. The sources of income remained very much the same except for £500 allocated from the Charities Fund of the British Medical Association, for which the committee of the Benevolent Fund was extremely grateful. If this was all new money it was most satisfactory. A generous donation, amounting to £525, had again been received from the Medical Insurance Agency, together with 100 guineas towards the Christmas Gift Fund. Another thing for which the Fund was indebted to the British Medical Association was the suggestion which that Association had made to its members when sending their annual subscriptions to add a certain amount for charity. The sum received as a result of these reminders in 1926 was £1,141, being £51 more than in the previous year. One increasing source of annual income was subscriptions from Panel Committees and local bodies of medical men. The highest subscription in this category was £50, from the Leicester Union of Medical Practitioners. An interesting subscription had come from as far away as Thursday Island, from which outpost a medical officer wrote that he had read with interest and sympathy the accounts of the work of the Fund appearing in the BRITISH MEDICAL JOURNAL, and hoped to send a yearly cheque. On the disbursement side the number of persons who received relief in 1926 was 622, an increase of 52 on the year before, and the relief given had been in 444 cases by means of grants, and in 178 by means of annuities. The amount expended in grants was £5,934, an increase of £563, and in annuities £4,836, an increase of £965.

Dr. NEWTON PITT, one of the honorary secretaries, said that the income was still insufficient for the demands made

upon the Fund. Many of the grants were quite inadequate. It had come within the knowledge of the committee that there were a number of medical men, from 50 to 65 years of age, who lost their practice during the war and had been unable to recover it or to find more than casual employment; some of them were practically starving. During the past year there had been an increase of 52 in the number of applicants for assistance, and not only so, but the distress in individual cases was more acute than formerly. The total number of annuitants had been increased by 11, and the Fund now maintained 26 annuities of £40, 24 of £30, 44 of £26, and 54 of about £20. Dr. Newton Pitt, like his colleague, referred appreciatively to the efforts put forward by the British Medical Association, though he thought the Association would find it by no means an easy matter to secure and maintain any large addition to subscriptions over and above the sources which the charities had already tapped, but the help that was being given was most valuable, and much was hoped from it. Dr. HOWARD STRATFORD said that he believed the British Medical Association was well aware of the difficulty of geting fresh subscription revenue, but it was being encouraged in its efforts.

Sir Thomas Barlow as President, Sir Charters Symonds as treasurer, and Dr. Newton Pitt and Mr. Handfield-Jones as honorary secretaries, were all re-elected, with thanks for their past services, and the committee of management was reappointed, with some slight variations in personnel. Speaking to one of the resolutions of thanks, Dr. C. O. HAWTHORNE said that, although the Fund made its principal appeal to members of the medical profession, contributions from laymen and lay bodies were occasionally received. It sometimes happened that a patient, when he came to pay his doctor's bill, was struck with the disparity between the amount he was asked to pay and the benefit he had received, and in that case a further contribution on his part to the Benevolent Fund would be a tactful and much appreciated way of further discharging his obligation.

New South Wales.

CHAIR OF PSYCHIATRY.

AT a meeting of the Senate of the University of Sydney held in December, 1926, Dr. William S. Dawson was appointed to the professorship of psychiatry rendered vacant by the retirement of Sir John Macpherson. The new professor is a graduate of the University of Oxford (B.A. 1914, M.A. 1918, M.B., B.Ch. 1918, M.D. 1923), is M.R.C.P. London, and holds the Diploma in Psychological Medicine of the University of London. He served for a period of three years in the great war. Dr. Dawson is at present a lecturer in clinical psychiatry in the University of London and senior assistant at the Maudsley Hospital, London, where he has been engaged in teaching students, graduates, and medical officers of mental hospitals. He has had an extensive experience in early cases of mental disorder, and has written papers bearing on psychiatry. He recently spent ten months in the United States as Rockefeller Research Fellow, studying the psychiatric training and the organization of social workers, but principally engaged in research in clinical psychiatry under Professor Meyer at the Phipps Psychiatric Institute, Johns Hopkins Hospital, Baltimore, where he also acted as instructor in medical psychology.

CANCER RESEARCH.

The Cancer Research and Treatment Organization of the University of Sydney has issued a pamphlet containing information for intending applicants for the post of director. A seven-year whole-time appointment is offered at an annual salary of £2,000. The director will be required to have qualifications in some branch of cancer research or treatment; he must be able to take a broad view of the various problems of cancer, have a grasp of the fundamentals of such sciences as are applicable to some of these problems, and possess administrative and organizing ability. A short account is given of the progress made since the beginning of 1921, when a Cancer Research Committee was appointed by the Senate of the University. During the last three years work has proceeded along three main lines—namely, the biophysical, biochemical, and the biological and pathological. A biophysical laboratory has been established, and the effect of homogeneous radiations upon living tissues is being investigated by biologists, physicists, and clinicians, with a view to improving radiotherapeutic technique. Biochemical investigation of malignant tissues and of the body fluids, and of cancerous patients before and after different methods of treatment, is being carried on in the University and the hospital laboratories. The organization is now undertaking treatment as well as research, and is urging the Government of the Commonwealth of Australia to establish a radium bank with a stock of eight grams of the radium for Australian use. In the middle of 1926 an appeal was made for £100,000 to endow research and treatment, and £130,000 has already been received.

Scotland.

SCOTTISH UNIVERSITIES PARLIAMENTARY REPRESENTATION.

A MEETING representative of the Socialist Teachers' Society, the University Labour Club, and the National Labour party was held in Glasgow on April 6th. Mr. Hugh B. Guthrie, M.A., was adopted as the Socialist candidate for the vacancy in the parliamentary representation of the Scottish Universities. Mr. Guthrie accepted the invitation to stand as Socialist candidate and delivered an address to the meeting.

LECTURES ON MENTAL DEFICIENCY.

The Scottish Association for Mental Welfare has arranged a course of lectures on mental deficiency for medical practitioners, more especially those who are engaged as school and parochial medical officers. The course is the first of its kind that has been attempted in Scotland, and the success which has attended those arranged by the Central Association for Mental Welfare in London encourages the Scottish Association to hope for similar success in its venture. The value of such a course to those whose work lies in this direction cannot be doubted, and the eminence of the lecturers whose services have been secured ensures that the various aspects of the subject will be adequately dealt with. The course will be held in Glasgow during the first week in May, and particulars may be had from the secretary, Mr. A. Wright, Education Offices, Paisley.

SMALL-POX IN DUNDEE.

At Dundee, on April 3rd, three lascars in the crew of the liner *Macharda* were found to be suffering from a mild form of small-pox and were removed to the Isolation Hospital. The steamer was on a voyage direct from Calcutta to Dundee with a cargo of jute, and it appears probable that a similar case (or cases) which had not been notified was the original cause of the outbreak in the town. On April 5th sixty-six persons were known to have suffered from small-pox, and sixty were in hospital; the other six were discovered only after recovery, and were in a reception house. The medical officer of health has reported that up to this date 8,200 school children had been vaccinated at the request of their parents. In the diagnosis of cases, the test elaborated by Dr. M. H. Gordon, F.R.S., of London has been used with success. With the exception of four adults who had been vaccinated in infancy, all the cases of small-pox occurred among unvaccinated persons, chiefly children. A house-to-house visitation is being carried out in the infected area, which is confined to the east end of the city, and a special staff is engaged on vaccination work. Lymph sufficient for 16,000 persons has been issued, and centres for vaccination have been established. Arrangements are also being made for the vaccination of employees at works and of the inmates in institutions as well as children at the schools.

Difficulty is experienced in recognizing some of the cases on account of their extreme mildness, and also in differentiating cases from chicken-pox, which has now been made generally notifiable throughout Scotland. Vaccination with ordinary calf lymph appears to afford protection both against ordinary small-pox and this mild variety. The convener of the public health committee has stated that even if the outbreak were to come to an end immediately it would have cost the municipality at least £10,000, which represented 2d. in the £ on the rates.

INSTITUTIONS FOR MENTAL DEFECTIVES.

At the sixty-sixth annual meeting of the Royal Scottish National Institution for Mental Defectives at Larbert, Stirlingshire, the directors reported that it had been necessary to realize most of the investments in order to take advantage of the opportunity to acquire the Larbert estate, which was near the institution and eminently suitable for the colony which it was proposed to build and equip for 300 adult mental defectives. A further sum of £70,000 would be required within the next two years to complete the buildings. The institution at Larbert was the only voluntary one at present existing in Scotland for the care of all classes and all grades of juvenile mental defectives. It was essential for the welfare of many of these that accommodation should be provided where they could be kept on and trained as adults to do some useful work under safe conditions. This would be achieved by the new colony. The Edinburgh District Board of Control is taking steps for a new institution for the treatment of mental defectives at Gogarburn. This is intended to accommodate about 1,000 patients, and will be available for patients from the south-east of Scotland area. The first step in the development of the new institution was taken on March 28th, when the first sod of a new roadway in connexion with the institution was cut by Mr. William Elliot, chairman of the District Board of Control. A beginning is to be made next month with the building, which is the first part of the scheme, and which it is expected will be completed in about three years.

NEW EDINBURGH DENTAL HOSPITAL.

The annual meeting of the Edinburgh Dental Hospital and School was held on March 31st. Dr. William Guy, dean of the school, who was in the chair, said that in his opinion the institution did more than any other agency to prevent the incidence of disease among the Edinburgh public, and yet when it appealed to the generosity of that public for support it received in the course of twelve months contributions amounting to about £60. It was high time that the general public realized that what had been done during the past generation was due to self-denying work by members of the dental profession. Otherwise the hospital would not now have been in existence. The income derived from the students had been used to build up the extension and equipment of the present hospital, but it must get in the immediate future between £10,000 and £20,000 for the support of the new building. Bailie T. G. Nasmyth, M.D., in moving the adoption of the annual report, said that the past year had been one of great activity and progress; the hospital practice had been attended by 144 students, and nearly 26,000 dental operations had been performed during the course of 1926.

GLASGOW HOSPITAL FOR WOMEN.

At the fiftieth annual meeting of subscribers to the Glasgow Hospital for Women, on April 7th, the Earl of Home, K.T., who presided, traced the history of the hospital from its beginning in 1877 in a small house as a hospital for women and children; since 1888 it had confined its activities to the care of women, and it had now become one of the most important institutions in the city. It had had a struggling existence for a long time, but in recent years its financial position had become secure. Lord Home paid a warm tribute to the services of the matron and staff, and in the name of the directors and staff presented Dr. G. Scott MacGregor, the senior surgeon, who has been connected with the institution for the long period of thirty-four years, with a canteen of cutlery and a gold cigarette case.

PERTH ROYAL INFIRMARY.

The eighty-ninth annual report of the Perth County and City Royal Infirmary showed that the number of cases treated throughout the year in all the departments was 4,051, as compared with 3,752 in 1925. Lord Forteviot, who had already met the cost of building the new maternity ward, had signified his intention of giving also the medical equipment and instruments. The late Mrs. C. A. Murray of Taymount bequeathed £5,000 for the endowment of a ward in memory of her late husband.

PUBLIC HEALTH INSTITUTES IN LANARKSHIRE.

The Middle Ward district committee of the county of Lanark contemplates the provision of five public health institutes in its area. The first of these, on the site of the county housing scheme at Johnson Drive, Cambuslang, was opened last month. The building cost about £7,500, and is intended for the treatment of children up to 5 years of age, nursing and expectant mothers, tuberculosis, and general infectious diseases of the skin. The second public health institute was opened the following week at Station Road, Shotts; the cost of this building is about £4,000, part of which is met by a Government grant. Other similar institutes are to be established at Blantyre, Larkhall, and Bellshill.

CENTRAL MIDWIVES BOARD FOR SCOTLAND.

At a special meeting of the Central Midwives Board for Scotland for the hearing of penal cases, Dr. James Haig Ferguson in the chair, a certified midwife was cited to appear for failure to take and record the pulse and temperature of her patients, and for other breaches of the rules. Miss Barker, assistant inspector of midwives for Glasgow, was present in support of the charges. The board found the charges to be proved, and instructed the secretary to remove the name of the midwife from the roll and to cancel her certificate. At the same sitting another certified midwife was charged with being guilty of negligence, breaches of the rules, and that she had proved herself incapable of carrying out the same, and, further, with failure to intimate intention to practise as required by the Act. The board found the charges to be proved, and instructed the secretary to remove her name from the roll and to cancel her certification, and, further, to prohibit her from attending women in childbirth in any other capacity.

Ireland.

LOCAL AND PART-TIME MEDICAL REFEREES.

AT a recent meeting of the Tyrone Division of the British Medical Association, Dr. Thompson, who was in the chair, said that it had been called to consider the attitude to be adopted towards the proposal of the Northern Government to appoint part-time local medical referees to review the medical certificates for sickness benefit under the National Health Insurance Act. Such medical referees would be in competition for private practice with the doctors whose certificates they were appointed to review. The matter, he said, had been considered at a meeting in Belfast of the Ulster Branch council of the British Medical Association, when it was decided to call a meeting of the Branch to consider the question, which was of vital interest, not only to the medical profession, but also to the poor. Dr. Thompson strongly disapproved of the proposition as being opposed to the best interests of the doctors and their insured patients. He urged that if the principle was once admitted of permitting local doctors to review other local doctors' certificates, and this without any special remuneration to the latter, two of the chief rules guiding doctors in their relationship would go by the board. In the South of Ireland the difficulty was solved by the appointment by the Government of three whole-time medical referees, and if three were enough for the South of Ireland, two referees should be enough for the Ulster six counties. A long discussion took place. Dr. Lagan

mentioned a case where a referee examined a delicate patient with heart disease and certified him fit for work. Dr. Lagan, who had been attending the case for weeks, had a different opinion, and this patient was later examined in his presence by another medical referee, and Dr. Lagan's opinion was confirmed—the patient being certified unfit to work. Dr. McAllister thought that the appointment of local referees was a good idea, but that efforts should be made to allow no local referee to come within ten miles of another medical practitioner who was also a medical certifier, to review his cases. Dr. Patrick proposed that the Tyrone doctors should vote against the appointment of local and part-time medical referees, and Dr. Lyle seconded. A motion to the opposite effect was proposed by Dr. McAllister, and seconded by Dr. Cunningham, but this was rejected by fourteen votes to three. The original motion was then put and carried by the same majority. A deputation, including the chairmen of the Ulster Divisions of the Association, was appointed to wait upon the Minister of Labour and to protest strongly against the appointment of part-time medical referees, as any arrangement by which local medical practitioners would review the patients of their colleagues was professionally objectionable, and unfair to the insured.

MEDICAL INSPECTION OF SCHOOL CHILDREN.

At a recent meeting of the Dublin Borough Commissioners Dr. Dwyer (City Commissioner) submitted a report recommending a preliminary scheme for the inspection and treatment of school children. The medical officer of health (Dr. Russell) had previously recommended the appointment of two assistant medical officers of health to act as school medical officer and assistant school medical officer respectively, together with two nurses. Dr. Dwyer recommended the immediate appointment of two permanent whole-time assistant medical officers of health, one to act as school medical officer at a salary of £700-£40-£900, the other as assistant school medical officer at a scale of £500-£20-£700, and two nurses at a salary of £182 10s. each. Dr. Russell advised that the school medical service might with advantage be co-ordinated with the working of the maternity and child welfare scheme, with the object of securing a uniform system of treatment. This would result in the compilation of a complete record for each child from the date of birth to the end of school life. Dr. Dwyer fully endorsed this view, and recommended that the school medical officers be also required to undertake medical work in connexion with the child welfare scheme, and that their salaries be charged equally against the two services. The report was adopted.

England and Wales.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

IN connexion with the rebuilding scheme of the Royal Westminster Ophthalmic Hospital a reception was held on April 6th in the Westminster City Hall. The Mayor of Westminster, Councillor Bucknill, who opened the proceedings, referred to the founding of the hospital in 1816 by Mr. Guthrie, an army surgeon, in his own house in Berkeley Square, whence it was later moved to King William Street. Like the other notable charities in the city of Westminster, the work of the hospital—curative, educational, and scientific—was not confined within the boundaries of the city, but was of benefit to the whole world. In particular the valuable ophthalmic and aural work now done among school children was instrumental in reducing the number of street accidents, due so often to defective sight and hearing. The Earl of Desart, chairman of the rebuilding fund, said that the object of this meeting was to lay before the public the first special appeal launched by the Royal Westminster Ophthalmic Hospital for thirty years. The rebuilding of the hospital was forced upon them; the present building was no longer adequate for their work. A very good site had been found, and the present site favourably disposed of. Various generous donations had already produced £18,000, but the sum of £60,000 was still required. The new building would contain beds for paying patients, as well as increased accommodation for nurses and students. He appealed to those present to help them, not only with subscriptions, but by giving the appeal all the publicity in their power. Mr. H. Percy Adams, the architect of the new building, plans of which were exhibited in the hall, described some of the special features of the new hospital. The great aim was to make the hospital as light and cheerful-looking as possible. Mr. W. H. Macmullen, surgeon to the hospital, opened an address on ophthalmic surgery by a reference to Lord Lister, whose discoveries had been of such value to all surgery. Ophthalmic surgeons, however, were often debarred from the use of ordinary chemical antiseptics, which would injure the surface of the eye. A bacteriological examination, therefore, was made before any operation. The most common ophthalmic operation was the removal of cataract. Very erroneous ideas existed as to this condition, which, contrary to lay opinion, could usually be treated quite successfully by surgical means. A much more difficult condition was glaucoma; Mr. Macmullen described several methods of operating on this disease, and also various ways of fixing artificial eyes. Sir Richard Cruise then demonstrated some of the instruments used in the routine examination carried out daily in the hospital, including the giant magnet used for removing foreign bodies from the eyes, the ophthalmoscope, whereby the whole cavity of the eye could be illumined, and the slit-lamp. He pointed out that much interesting and sometimes surprising information as to a patient's condition was derived from an ophthalmological examination.

ROYAL VICTORIA AND WEST HANTS HOSPITAL, BOURNEMOUTH.

At the annual meeting of the Royal Victoria and West Hants Hospital, on March 30th, it was stated that out of 18,372 patients treated during 1926 nearly 4,500 had come from outside the boundaries of Bournemouth. Further extension of the hospital was required in several directions; the provision of a second operating theatre had become urgently necessary in view of the large increase in operations now being performed, and several additional one-bed and two-bed wards were needed for special cases, which could not be satisfactorily accommodated in larger wards. The ultra-violet light and *x*-ray departments were quite inadequate for the great amount of treatment that was now being given, and the work of the dental department was badly handicapped by being carried on in temporary quarters. The chairman of the board of management announced that the question of further extension of the hospital was being carefully considered by a special committee, and that sketch plans were being prepared. Though there had been a small deficit of £35 on the annual turnover of £34,000 during 1926, the treasurer anticipated that satisfactory improvement in this respect was probable in the coming years, provided that the support of the outlying districts could be obtained, in view of the fact that so many of the patients of the hospital resided outside the Bournemouth area. The cost of maintenance of patients had decreased by about 12 per cent., the only increase in any direction being attributable to the industrial dispute.

HEALTH OF SCHOOL CHILDREN IN GLOSSOP.

In his annual report as school medical officer for 1926, Dr. E. H. Marcus Milligan describes a method he adopted successfully to deal with the serious outbreak of diphtheria in Glossop during last summer and autumn. Out of the total 65 cases, 45 occurred in school children, and three schools were mainly affected, the infection being almost entirely limited to one side of the borough. All class contacts in these three schools were examined and some carriers were found, including two children from a farm which supplied milk to the affected area, and two children of one of the caretakers. The contacts were repeatedly swabbed, the carriers isolated, and, in addition, many children were treated with prophylactic serum without any special ill effects. Dr. Milligan supports the suggestion of Surgeon Commander F. Dudley that diphtheria may be effectively combated by immunizing large numbers of those likely to be infected, the bacillus losing its virulence by transmission through immunized carriers. He has also for

some time taken special interest in goitre, and now reports that this disease is milder and less prevalent among the children in Glossop since the adoption of systematic examination for thyroid enlargement and their prolonged treatment by iodostarin or by tablets containing 1/10 grain of iodine. Improvement was slow under this treatment, and Dr. Milligan thinks that the dose of iodine might safely be increased or augmented by the use of thyroid extract. He notes that goitrous children were frequently found to have nasal catarrhs, sore throats, or other septic infections. The examination of 1,000 children for rheumatic nodules, cardiac defects, and diseased conditions of the ear, nose, and throat showed that rheumatic stigmata were present in at least 10 per cent. of them at all ages.

Correspondence.

CARCINOMA OF THE HEART.

SIR,—Dr. Thomas Lindsay's report of a case of "Carcinoma of the heart" (BRITISH MEDICAL JOURNAL, February 19th, p. 325) in an old woman who had a nodule of squamous-celled carcinoma in the interior of the left ventricle is very interesting. It is quite obvious, however, that primary squamous-celled carcinoma is not the right term to apply. A squamous-celled carcinoma originally must come from a squamous-celled surface, and whether the primary growth has been found or overlooked does not matter very much—it must be somewhere. There is not the slightest doubt that emboli from primary carcinomatous growths become sown throughout the body, but the delicate cells will not grow in every locality; in certain organs, such as the liver, they grow readily, while in others, like the muscles, they seldom will. The reason for this is not known. One of the curious facts in connexion with it, however, is that squamous carcinoma of the tongue will very often give rise to secondary growths in the heart. This is not generally known, but struck me very forcibly in looking up the literature lately. Secondary growths from carcinoma of the tongue are seldom mentioned, since autopsies on these patients are not common when death takes place at home, and usually only early cases die in hospitals. In some institutions, however, autopsies may be met with and the figures can be obtained. Thus, in the *post-mortem* examinations of the Middlesex Hospital the heart was found affected on two occasions, the liver on eight, and the lungs and pleura on eleven, while in the literature on the subject frequent mention is made of secondary nodules in the heart. Thus, almost offhand, I can mention the following instances: Féré[1] records three nodules, one in the wall of the left, and two in the wall of the right ventricle, in a man aged 64. Godlee[2] notes an instance in a man aged 56, and Weil[3] and Jeanne[4] each record cases.

One can only wonder if the tongue in Dr. Lindsay's case was carefully examined. The commencing degeneration mentioned in the tumour is often seen in secondary growths from the tongue.—I am, etc.,

London, W.1, April 5th. DUNCAN C. L. FITZWILLIAMS.

THE SURGERY OF GASTRIC AND DUODENAL ULCERS.

SIR,—In his letter in the issue of the BRITISH MEDICAL JOURNAL of April 2nd (p. 643) Mr. E. R. Flint takes exception to my statement that, of 1,275 cases of gastric and duodenal ulcers admitted to the surgical wards of the London Hospital in the three years 1923-25, 660 were gastric and 615 were duodenal, and implies somewhat directly that the surgeons at the London Hospital are unable to distinguish between a gastric and a duodenal ulcer.

I think that his implication is probably entirely correct, and that the disability is shared by other surgeons if they would only admit it. It is perfectly true that, as he says, the white line and the pyloric vein define with considerable accuracy the anatomical position of the exit of the pylorus, but in a large number of cases there is no means of judging the extent of an ulcer, or even its precise situation from the external appearances of the pylorus and the duodenum. There will therefore be a large proportion of cases in which the question of whether the pylorus is or is not involved remains a matter of some doubt, and as it is the custom of some surgeons to classify as gastric all cases where they suspect the pylorus to be involved, there is room for a very wide variation in statistics.

Thus Walton states that among his own cases the numbers of uncomplicated lesser curve and duodenal ulcers are exactly equal, whilst Eggleston,[1] in a series of 500 cases, allots 415 to the duodenum and 85 to the stomach. W. J. Mayo has in various papers given an incidence of duodenal ulcers at figures varying from 60 to 73 per cent. Pannett places an incidence of 57 as the generally accepted figure.

The *post-mortem* records at the London Hospital, which surely cannot lie, give 68 gastric ulcers and 55 duodenal over a certain period, but this cannot, of course, be accepted in the same category as operation statistics, as the question of mortality enters into the calculation.

In the last 100 cases on which I have myself personally operated I consider that 54 were gastric ulcers and 46 duodenal. When I was in charge of the surgical unit at the London Hospital we paid special attention to this very point, and the cases operated upon by myself and my assistants were distributed as follows: 47 were gastric ulcers, 53 duodenal, and 17 pyloric.

The question whether in any specific case an ulcer should be described as duodenal or pyloric is often exceedingly difficult to answer, as the few statistics I have quoted are sufficient to indicate. The question can only be settled, if it can be settled at all, by a larger series of gastro-duodenectomies than has yet been published.—I am, etc.,

London, W.1, April 9th. H. S. SOUTTAR.

THE NUMBERS OF THE PROFESSION.

SIR,—The glut in women doctors still continues. A single advertisement inserted in the BRITISH MEDICAL JOURNAL produced forty-eight women applicants for two posts—namely, those of senior and junior resident medical officers to a children's hospital in the North of England, the salaries being £120 and £100. Recently a like advertisement brought forth only twelve male candidates for the post of house-physician at our general hospital.

None of the former applicants gave her age as over 29. Thirty-eight of the candidates had held previous hospital appointments lasting from two to fifty months. Many had gone from post to post. All the applicants were university graduates except one, who held the conjoint diploma of the London colleges.

Twenty-three had English qualifications, 21 Scottish, and 4 Irish (one from Northern Ireland and 3 from the Free State). The 23 English women had degrees from: Oxford 1, Durham 4, London 10 (University 9, Conjoint Colleges 1), Birmingham 1, Liverpool 3, and Manchester 4. The 21 Scottish graduates were: 3 from St. Andrews, 6 from Edinburgh, 8 from Glasgow, and 4 from Aberdeen. The Irish graduates were: 1 from Belfast and 3 from Dublin.

The large number of Scottish applicants was out of proportion to the numbers qualifying across the border. Of over 2,000 new names added to the *Medical Register* last year from Great Britain, two-thirds were from England and one-third from Scotland, although Scotland has only one-seventh the population of England.

As regards the excessive number of graduates (men and women) entering the profession in face of the falling sickness rate—the *Medical Register* already contains over 53,000 names—it is said that out of every three qualifying in Ireland two must emigrate; the proportion must be higher from Scotland. Abernethy, at the first meeting of his annual class of medical students, once exclaimed, "Good

[1] Féré: *Bull. de la Soc. de Anat.*, 1880, lv. 512.
[2] Godlee: *Trans. Path. Soc.*, 1881, xxxii. 27.
[3] Weil: *Gaz. hebd. de méd.*, 1837, 570.
[4] Jeanne: *Gaz. hebd. de méd.*, 1837, 737.

[1] *Journ. Amer. Med. Assoc.*, December 6th, 1920, p. 1542.

God, gentlemen, what will become of you all?" We may say the same to-day.

Some of the best American universities (Pennsylvania, Baltimore, etc) restrict their medical students to a fixed number which can be adequately taught the practical side of their work, some of them admitting less than a quarter of the applicants, and selecting only the best after inquiry and examination.—I am, etc.,

Sunderland, April 7th. W. ROBINSON.

CERTIFICATION OF THE INSANE.

SIR,—Your admirable leader on the Hume-Spry case leaves an important point undeveloped which nevertheless adds to the danger to the general practitioner in certifying mental cases. I refer to a statement emphasized by Sir James Barr at the annual meeting of the Royal Liverpool Infirmary on March 31st last. "The medical man knew that an individual with money could sue him and always command expert evidence that he was sane." This is surely a serious accusation.

In the case under consideration the judge and jury made short shrift of such evidence—evidence be it remembered given by "experts" who did not see the patient at the time he was certified. In a later case (de Freville *v.* Dill) the following quotations from the *Times* report speak for themselves:

Mr. Maitland: If a doctor has left any stone unturned, is it proper to give a certificate of insanity?—No.
Mr. Singleton: Is not that for the jury?
Mr. Justice Avory: I think the answer means that no doctor should ever give a certificate of insanity unless he has consulted Dr. Hyslop.

And further, from the *Times* report of Dr. Risien Russell's cross-examination:

Mr. Singleton: Do you say, because Dr. Dill said that she refused food, that he wilfully made false statements to strengthen a medical certificate?
Dr. Russell: He made the statement to strengthen the certificate. He either did it wilfully, or he is very ignorant of what is required in a medical certificate. He himself says that she had a cup of tea.
Mr. Justice Avory: May not a reasonable man think that a cup of tea is not food?
Dr. Russell: Not a medical man, my lord.
Mr. Justice Avory: I said a reasonable man. (Laughter.)

I think we may all join in the laughter.—I am, etc.,

F. E. H. DAUNT, L.R.C.P.I., L.R.C.S.E.

London, S.W.9, April 5th.

"BIRTH CONTROL."

SIR,—In the letter (April 9th, p. 701) combating my contention that the world's food supply is increased so slowly that only a very small proportion of couples in the world can get really sufficient food for themselves and more than three children, Dr. S. Vere Pearson quotes from a League of Nations publication that between 1913 and 1925 the world's output of foodstuffs was increased by 13 per cent. This important estimate that the world's food supply is only being increased at a rate of about 1 per cent. per annum precisely accords with my contention. It indicates that if all are to be adequately fed the world's inhabitants cannot have a birth rate of much more than 20 per 1,000, and this implies that the great majority of couples cannot have more than three children.—I am, etc.,

London, S.W.7, April 9th. B. DUNLOP.

Obituary.

DR. JAMES HARRIS GARCIA WHITEFORD died suddenly on March 26th at his residence at Greenock. Dr. Whiteford, who for a considerable time had been medical officer of health to the burgh of Greenock and physician to the Greenock Infirmary and Fever Hospital, was a son of the late Dr. James Whiteford of Greenock, where he was born in 1865. He graduated B.A. at Cambridge in 1886, and M.B., C.M. at Edinburgh in 1891, and took the diploma in public health at Cambridge in 1900. At one time he served on the town council; he took a great interest in Freemasonry and in the local Territorial Force, attaining the rank of lieutenant-colonel R.A.M.C. Dr. Whiteford is survived by his wife and two daughters, one of whom is a medical practitioner in Greenock.

DR. WILLIAM HAMMOND HODGSON, whose death is recorded at the age of 45 years, was born at Poulton, the son of Alderman William Hodgson, J.P. He was educated at the London Hospital and the University of Cambridge, took the diploma of the English Conjoint Board in 1907, and graduated B.A.Camb. in 1902, and M.B., B.Ch. in 1911. He served as house-physician, senior clinical assistant to the ear, nose, and throat department, and resident anaesthetist to the London Hospital, and after working in London for a time removed to Blackpool, where he carried on a successful practice. He joined the Victoria Hospital in 1914, to which he was surgeon at the time of his death, and in 1921 was elected the representative of the medical board on the board of management. During the war he served for twelve months in Mesopotamia, and subsequently took charge of the Station Road (South Shore) Auxiliary Hospital, Blackpool. Dr. Hodgson was a member of the Blackpool Division of the British Medical Association. He is survived by his widow and a young daughter.

DR. EDWARD JOHN JOSEPH QUIRK, M.B.E., who died on March 24th, received his medical education at Charing Cross Hospital, where he obtained the diplomas M.R.C.S., L.R.C.P. in 1908. After serving as house-surgeon and house-physician to Charing Cross Hospital, and house-anaesthetist to the Royal Dental Hospital, he was appointed to the West African Medical Service in 1912. In the late war he received a commission as captain and was attached to the West African Field Force from 1914 to 1916, and to the Nyasaland Field Force from 1917 to 1918. He was mentioned in dispatches and awarded the M.B.E. A colleague writes: By his death the staff has lost one of its most promising officers. A sound physician and an expert anaesthetist, Dr. Quirk was also very efficient at administrative work, so that he was marked out for early and high advancement in the service. As regards his personal character, he was kindness and generosity personified. These qualities, added to his never-failing fund of wit and tact, endeared him to all.

DR. JOHN THOMAS CROWLEY, who died on March 18th, at the age of 28, received his medical education at University College, Dublin, where he graduated M.B., B.Ch., B.A.O. in 1921. He was then appointed resident surgeon to the Mater Misericordiae Hospital in Dublin, and in 1922 obtained a commission in the Irish Free State Army. He held the position of command medical officer in Cork until April, 1924, when he was promoted to the rank of commandant on the inspection staff. Ill health compelled him subsequently to resign his commission.

FREDERICK BELDING POWER, Ph.D., LL.D., who died on March 30th at Washington, was born in 1853 at Hudson, New York, and began life as a practical pharmacist in Chicago and Philadelphia. In 1876 he went to study at the University of Strasbourg, where he took his degree in 1880, after acting as assistant to Professor Flueckiger. Returning to America in 1881, he became in turn professor of analytical chemistry at the Philadelphia College of Pharmacy, and of pharmaceutical chemistry and materia medica at the University of Wisconsin. In 1896, at the invitation of Mr. Henry S. Wellcome, Dr. Power came to England as first director of the Wellcome Chemical Research Laboratories. Under his direction 168 scientific papers from these laboratories were communicated to learned societies, and during this period Dr. Power gained a wide reputation as a research chemist, particularly in the field of plant chemistry. One of his most important researches was an investigation of the constituents of chaulmoogra and hydnocarpus seeds. In 1914 Dr. Power returned to America as director of the Phytochemical Laboratory of the Bureau of Chemistry at Washington, a post he held

until his death. In 1908 the University of Wisconsin conferred on him the honorary degree of Doctor of Laws, and in 1913 he was awarded the Hanbury gold medal. In 1921 Mr. Wellcome presented him with a commemorative gold medal. Dr. Power was an honorary member of many scientific societies and institutions, a former vice-president of the Society of Chemical Industry, and served on the committee of the United States Pharmacopoeia; in 1920 he was elected vice-president of the United States Convention.

The following well known foreign medical men have recently died: Dr. ANTONIO CARDARELLI, professor of *clinical medicine* at Naples, aged 96; Professor PERTHES, director of the Tübingen Surgical Clinic; Dr. JEANNE, professor of clinical surgery at the medical school at Rouen; Dr. ZOEGE VON MANTEUFFEL, extraordinary professor of surgery at Dorpat, aged 68; Professor RIELÄNDER, a Marburg gynaecologist, aged 48; Professor SPIEGEL, who discovered the alkaloid yohimbin; Dr. GIOVANNI D'ABUNDO, professor of clinical neurology at the University of Catania; Dr. J. SINGER, formerly professor of internal medicine at Prague, aged 72; Professor A. VALENTA EDLER VON MARCHTURN, gynaecologist at Laibach, aged 57; Dr. PAUL CORNET, general secretary of *Paris médicale;* Dr. PAUL RIBIERRE, a Paris cardiologist, aged 52; Dr. LANGLET, national associate of the Académie de Médecine, and formerly mayor of Rheims; Professor J. CURTILLET, dean of the faculty of medicine of Algiers, aged 64; Professor GAVELLO, *director of the öto-rhino-laryngological clinic* at Turin; and Dr. LÉONCE PIERRE MANOUVRIER, director of the laboratory at the Collège de France and professor at the Ecole d'Anthropologie.

The Services.

Brevet Colonel William Westropp White, C.B., *C.M.G., Bengal* Medical Service (ret.), died at Cove, Bampton, Devon, on March 21st, aged 64. He was born on June 10th, 1862, the eldest *son* of the late John Carpenter White of Cork, and was educated at Queen's College, Cork; he graduated as M.D., M.Ch., and M.A.O., of the Royal University, Ireland, in 1887. He entered the I.M.S. as surgeon on October 1st, 1887, he became lieutenant-colonel after twenty years' service, and received a brevet colonelcy in 1915. He retired on August 2nd, 1921. He had a *long* record of war service—North-West Frontier, Hazara campaign of 1891, medal with clasp; Chitral, 1895, relief of Chitral, medal *with* clasp; Tirah, 1897-98, operations on the Samana range and in the Kurram Valley, and in Buner, two clasps; China, 1900, relief of Pekin, mentioned in dispatches in *London Gazette* of May 14th, 1901, medal with clasp. He also served throughout the recent war, in France, Mesopotamia, and Palestine successively, was four times mentioned in dispatches (1915, 1916, 1918, and 1919), and received the C.B. on January 1st, 1916, and the C.M.G. on June 3rd, 1919.

Lieut.-Colonel David MacDonald Davidson, C.I.E., Bengal Medical Service (ret.), *died at Lahore on March 13th, a few days before* his sixty-second birthday. He was born at Antananarivo, in Madagascar, and was educated at Aberdeen, where he graduated M.B. and C.M. with honours, and gained the Murray scholarship in 1897; he proceeded M.D. in 1896, and took the D.P.H. of the Glasgow Colleges in 1897. He entered the I.M.S. as surgeon in October, 1887, became lieutenant-colonel after twenty years' service, and retired in October, 1923. After two years' *military* duty he entered civil employment in the Punjab, where he was for many years civil surgeon, first at Delhi and afterwards at Lahore, *and in* December, 1914, was appointed professor of midwifery in the Lahore Medical College, in addition to his duties as civil surgeon. On his retirement he came home, but after a short period in Europe returned to India and settled at Lahore, where he served as a municipal commissioner. *He received the C.I.E. in* January, 1921. He was the author of the article on dysentery in his father's well known work, Davidson's *Hygiene and Diseases of Warm Climates,* published in 1893

Major Roger Durrant Willcocks, Indian Medical Service (ret.), died on January 9th, aged 50. He was educated at Liverpool, where he graduated M.B. and Ch.B. of the Victoria University in 1901, and entered the I.M.S. as lieutenant in January, 1902. He attained the rank of major on July 29th, 1913, and retired on October 12*th*, 1920. He served in the recent war.

Major Sorab Dinshaw Billimoria, Indian Medical Service, died *on February 2nd,* aged 41. He was born in 1885, and was educated at the Grant Medical College, Bombay, where he obtained the *diploma* of L.M.S. in 1910. He joined the I.M.S. as a temporary lieutenant on January 4th, 1915, and received a permanent commission, ranking from his original date of entry, in November, 1920. He served throughout the great war, in Egypt in 1915-16, and in *Mesopotamia in 1918, and was mentioned in* dispatches on August 15th, 1917.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

ON April 7th the Parliamentary Medical Committee visited the National Research Institute, Hampstead, and the Mill Hill experimental farm. The Committee were very favourably impressed by the organization at both. All departments were visited, special attention being paid to the research into rickets and to the section of applied physiology. At Mill Hill the *Committee saw the arrangements for the investigation of* distemper in dogs and of Johne's paratuberculous disease in cattle, and also the ultra-microscopic work of Dr. Gye and Mr. Barnard, for which a special building has now been provided.

The Budget.

Mr. Churchill presented in the House of Commons, on April 11th, the Budget for 1927-28. This showed an estimated expenditure for the year of £833,390,000, *including* a provision of £65,000,000 for Sinking Fund, and an estimated revenue of £796,850,000 on the basis of existing taxation. Mr. Churchill proposed to increase this revenue to £834,830,000. An additional £14,800,000 is to be obtained by collecting income tax under Schedule A for 1928 in one instalment next January, and £12,000,000 will be *transferred from the* Road Fund reserve to general account. New duties are proposed on imported tableware, on imported motor tyres, and on British wines, and the *duties on "fortified" foreign* wines are increased. No change is made in the rates of income tax nor in the motor car duties, but the Chancellor announced important changes *in income tax administration to take effect* next year. Taxation under Schedule E (salaries) will be transferred to the basis of the previous year; supertax and income tax are to be harmonized into a *single graduated tax on income,* and taxpayers will make a single annual return for all purposes of the total income for the previous year. Mr. Churchill further announced that the Government had decided to abolish the Ministry of Transport, Mines Department, and Department of Overseas Trade, and to slow up the rate of entry for the civil service.

At the close of the day's sitting a resolution giving the force of law to the duty on "patent" medicines was carried by the House. The debate on the Budget duty was resumed on April 12th and 13th.

Landlord and Tenants Bill (No. 2).

On April 7th the Home Secretary, Sir William Joynson-Hicks, moved the second reading of the Landlord and Tenants *Bill (No. 2),* which would entitle the tenants of leasehold business *premises* to compensation for goodwill and for improvements made after the passing of the bill, or alternatively to renewals of *their leases.* The bill also proposes to set up a tribunal of arbitrators to deal *with questions* in dispute between landlords and tenants. Mr. Dalton, moving an amendment on behalf of the Labour party, regretted that the bill was limited to business premises. A large number of doctors, dentists, and other professional people were liable to suffer from confiscation by their landlords, when their leases fell in, of the goodwill which they had added to their practices. In the poorer parts of London doctors had built up considerable practices. When their leases fell *in they* must be turned on the streets or in the alternative pay a grossly excessive rent to the landlords who were aware of the amount of goodwill that had been created around these practices. Mr. MacLaren, seconding the amendment, said it was laid down in law that professional men had their goodwill assessable for Probate Duty and other purposes. Mr. Ellis Davies said the solicitor as a rule was not entitled to goodwill in respect of the premises which he occupied, but the doctor's connexion was much more personal and therefore the doctor ought to be included within the scope of the bill. Dr. Graham Little urged the extension of the provisions of the bill to the professional premises of doctors. Two classes of doctors were concerned. The first were the consultants who were resident in London. Under the present law a surgeon would take a house for a short period, would establish a great reputation, and at the end of some years would be faced with the necessity of removal or of renewing the lease. The landlord understood it was a damaging thing for that man to remove from the neighbourhood, and the lease would immediately go up to an extortionate value. *Unless the bill applied* to professional premises it would make leases more difficult to obtain. The inland revenue regarded a doctor's house as business premises. The general medical practitioner would be, perhaps, more hardly hit. He read a resolution by a meeting of general practitioners urging the Government to make provision in the bill for the security of tenure of practitioners who had been in many instances compelled to build on leasehold premises to comply with the requirements of the National Health Insurance Act. The Solicitor-General, Sir Thomas Inskip, said Dr. Little's suggestion that doctors' goodwill should be made the subject of compensation was purely a question for the Committee stage. The Government had no desire to reject reasonable proposals for making the bill more effective. The second reading of the bill was carried by 240 to 83.

Shop Hours.

At the first sitting of the Committee which has been appointed to inquire into the working of the Shops Acts of 1920 and 1921 and to consider whether they should be made permanent, and, if so, whether with or without modifications, evidence was given by Mr. A. Larking, secretary of the Early Closing Association. He recalled the history of the early closing movement, and said that the habit of late shopping by the public had entailed suffering on the young people behind the counters. All over the country shops were open from 7.30 or 8 in the morning to 10, and midnight on Saturday, and the hours of assistants ranged from eighty to one hundred a week. The only safeguard was for all shops to be closed at a prescribed time, whether employing shop assistants or not. An additional reason for continuing the Shops Act of 1920 was its value in connexion with the Summer Time Act, which afforded time for outdoor recreation every evening of the week, instead of, as previously, only on the half-holiday.

Replying to Miss Margaret Irwin, a member of the Committee, the witness said that he had medical evidence that long hours were injurious to the health of women and men employed in shops.

The Chairman (Sir W. W. Mackenzie) said the Committee would like medical evidence since 1912. The witness said that since 1912 the number of hours worked had been much reduced, and the half-holiday and the Shop Seats Act considerably lessened the hardships of shop assistants.

The Chairman said if the evidence showed the injurious effect of long hours before the Shops Acts were passed it would not be very material. The witness replied that the hours to-day were not sufficiently long to warrant medical evidence against long hours. He could bring medical evidence that if the Shops Act of 1920 were discontinued, and things went back to the old state of affairs, keeping open to 9 or 10 at night, the effect on young people, especially girls, would be most injurious.

Replying to Miss Irwin, the witness said that work in shops at any time with artificial light was far more exacting than working in ordinary light. In some shops the sanitary conditions left a good deal to be desired.

The Committee adjourned till Thursday.

Opium and Drug Addiction.—Mr. G. Locker-Lampson denied that the League of Nations Advisory Committee on Opium and Drug Addiction had stated that in Europe 700,000 men and women were engaged in the illicit sale of morphine, heroin, and cocaine, a good percentage being employed in Great Britain. The statement was without foundation and had not been made by any responsible body.

Mr. Amery, replying to Mr. Gardner on April 11th, said that opium consumers were not registered in the Straits Settlements or Federated Malay States, though the Governments of those territories had put into operation measures designed to lead up to registration of consumers when possible. The Government of North Borneo had recently introduced an experimental and tentative system of registration of consumers of opium.

Cholera in India.—On April 11th Earl Winterton informed Mr. Short that the epidemic of cholera in the Bombay Presidency appeared to have started in the Dharwar district in February last and had spread to three other districts. Figures relating to these outbreaks had not yet been received. The measures taken to arrest the spread of the disease were a matter for which the local Government was responsible, but the Secretary of State had no reason to suppose that all possible steps to this end were not being taken. The Belgaum district was freshly infected on March 19th, and on March 26th the disease was spreading in that district.

Infantile Mortality in Palestine.—Mr. Amery has stated that the infant mortality rate per 1,000 births in Palestine was 184.83 in 1924, 188.64 in 1925, and 163.15 in 1926. Twenty-nine non-Government infant welfare centres had been established in Palestine, to many of which the Government centres had been established where addition, two Government centres had been established where training by experienced British nursing sisters was given to women who wished to take up infant welfare work. A training centre for midwives had been established, at which forty-three women had already qualified, and a scheme was on foot for establishing nursing clinics in a number of villages.

Poisons and Pharmacy Acts.—On April 11th Captain King told Dr. Fremantle that traders engaged in the sale of poisons, both by wholesale and retail, were represented on the committee which was investigating the working of the Poisons and Pharmacy Acts. He was unable to say when the committee's report might be expected. Lady Astor asked whether whisky was classed as a poison for the purpose of this inquiry. No answer was returned.

Notes in Brief.

The Home Secretary is about to make a scheme under the Workmen's Compensation Act which will embrace all the metal grinding industries, including the edge-tool trade.

The Ministry of Labour estimates that on March 21st last 10,702,000 insured persons were employed in Great Britain, as against 9,677,000 in July, 1922.

The Minister of Health is of opinion that the re-issue in casual wards of unwashed night clothing does not satisfy the existing regulations.

Material will be contributed by the Ministry of Health to the next Health Yearbook issued by the League of Nations.

The Consultative Council of the Ministry of Health last met on December 7th, 1921, and the Minister cannot say whether there is hope of its meeting again.

Medico-Legal.

A CORONER'S INQUEST.

On March 24th a meeting of the Southall Medical Society was held at the Manor House to discuss the matter of the inquest held at Westminster on March 15th last by the coroner, Mr. S. Ingleby Oddie, relating to the death of Lily Leah Wise, and circumstances arising therefrom. The meeting was called because of the strong feeling that an injustice had been done, and that a question arises affecting the medical profession generally. Dr. J. Davenport Windle presided, and all the members were present—namely, Drs. Hart, Wynn-Werninck, Hutchison, Brook, McKenna, and Seccombe.

The report of the proceedings at the inquest which appeared in the *West Middlesex Gazette* of March 19th was laid on the table. The coroner, in returning a verdict of accidental death, said that it was an unfortunate case of a young married woman losing her first child. In view of the difficulties the doctor had to contend with some injury might easily be received by the infant, but the abrasion on the scalp became infected and the infant died of pyaemia. The doctor should have seen that the abrasion was bathed with antiseptics and kept clean. The coroner added a rider regretting that the doctor had not supervised the keeping clean of the abrasion by the nurse or kept it clean himself. The chairman said that the remarks of the coroner, especially in the rider to the verdict, contained an unjustifiable reflection on the professional skill of Dr. McKenna. Professional witnesses had been unable to say whether the infective process originated in the abrasion or was conveyed by contagion from the mother. Dr. Weir, the pathologist, although of opinion that the origin of the condition was the wound on the head, properly admitted the possibility of infection from the mother. The chairman pointed out other possible sources of infection, including infection from the cord (sloughing of the cord), a common cause, and infection from the nurse. A member pointed out that infection was prone to occur in the case of any child whose weight at birth was much below the normal, due to prematurity or some hereditary cause. He asked why the nurse was not called at the inquest, and, as the question of the doctor's conduct had arisen, why there was no jury. Though it might be the coroner's duty to censure where the facts were incontrovertible, it was his duty, the speaker considered, to determine the cause of the death, and this he had failed to do. He had formulated an opinion and evolved out of it a reflection on a medical practitioner. A motion was unanimously adopted to send a copy of the minutes of the meeting, together with the local newspaper, to the British Medical Association and the Medical Defence Union.

Universities and Colleges.

UNIVERSITY OF OXFORD.

AT a congregation held on April 9th the following medical degrees were conferred:

D.M.—A. Kendrew.
B.M.—C. W. Mackenzie, Grace Batten.

UNIVERSITY OF LONDON.

THE following have been recognized as teachers of the University in the subjects and at the institutions indicated:

St. Bartholomew's Hospital Medical College.—Mr. Reginald Hilton (physiology).

Guy's Hospital Medical School.—Dr. William W. Jameson (hygiene).

Middlesex Hospital Medical School.—Mr. Stephen L. Baker (pathology—morbid anatomy and histology); Dr. Davis E. Bedford (medicine); Dr. Samson Wright (physiology).

London School of Medicine for Women.—Sir Bernard H. Spilsbury (forensic medicine).

St. Mary's Hospital Medical School.—Mr. Gerald R Lynch (pathological chemistry).

University College.—Mr. Albert Hemingway, temporary (physiology).

Dr. Hamilton Hartridge has been admitted to the Faculties of Medicine and Science as from September 1st, 1927.

Sir Holburt Waring, M.S., has been appointed a governor of the Imperial College of Science and Technology.

Mr. V. Warren Low has been reappointed the representative of the Royal College of Surgeons of England on the Senate, and Lord Dawson of Penn and Mr. H. L. Eason have both been reappointed as the representatives of the Faculty of Medicine.

Applications for the Chair of Anatomy tenable at King's College (salary £1,000 a year) must be received not later than the first post on April 21st by the Academic Registrar, from whom further particulars may be obtained.

Three lectures with lantern illustrations on sensation and the sensory pathway will be given on May 3rd, 4th, and 6th, at 4.30 p.m., by Professor J. S. B. Stopford at University College.

A course of four lectures with lantern illustrations on inflammation and infection will be given by Professor E. H. Kettle at Guy's Hospital Medical School on May 20th, 27th, 31st, and June 3rd, at 5.30 p.m.

Professor John Fraser will give a course of three lectures with lantern illustrations on some surgical problems at the Middlesex Hospital Medical School on May 16th, 17th, and 18th, at 5 p.m.

UNIVERSITY OF GLASGOW.

THE following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—W. Abdurahman, Margaret K. M. Alexander, H. Black, A. Blair, G. F. Cables, A. Campbell, J. Campbell, Margaret C. Campbell, Columba C. Capaldi, H. Dickie, J. Downes, D. J. Ferguson, J. S. Ferguson, J. A. Fleming, H. W. O. Frew, J. P. Galloway, T. Gibson, Mary L. Gilchrist, Marjorie Gillespie, W. H. Graham, W. F. Greer, B. M. Hegarty, J. Hepburn, J. Hill, *F. T. Land, H. V. Lavelle, J. L. McColm, E. C. Macdonald, [illegible] McGregor, A. A. McMillan, [illegible] R. A. Neill, R. L. Paterson, [illegible] Jeannie McC. Robertson, [illegible] A. Sharman, S. Sharman, J. S. Sharpe, J. B. Simpson, N. Smith, P. Spence, A. McD. Steele, J. R. Sutherland, Anne I. Symington, A. C. Thomson, Donella A. F. Watson, W. Watson, E. Yoddes.

* *Distinction in surgery.* † *Distinction in medicine.*

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council meeting was held on April 7th, when the President, Sir Berkeley Moynihan, Bt., was in the chair.

Honorary Fellowship.

The following honorary Fellows, elected by the Council on March 10th last, were introduced and received their Diplomas: Roberto Aless[illegible]m Archibald (Montreal), Frans Ali B[illegible] *Paul Lecène (Paris)*, René Leriche (New Orleans), Charles Willems (Liège).

Fellowship.

Diplomas of Fellowship were granted to Messrs. G. F. G. Batchelor and R. W. Jones, who have now complied with the regulations. Sir Henry Gauvain and Mr. Cecil Beadles, members of twenty years' standing, were elected to the Fellowship.

Prizes.

The Jacksonian Prize for 1926 on "The pathology, diagnosis, and treatment of abscess of the brain" was awarded to Mr. E. Miles Atkinson, F.R.C.S. (Bath). The subject for the Jacksonian Prize for 1928 is "The surgical treatment of pulmonary tuberculosis." The John Tomes prize for 1924–26 was awarded to Mr. Herbert Cecil Malleson, M.R.C.S., L.D.S., for his work in connexion with the histology and pathology of the dental tissues.

Mr. Robert Gordon Wilbond of Bristol University was appointed Begley Student for the ensuing three years.

Appointment of Representatives.

Sir Cuthbert Wallace was appointed delegate to attend the celebration of the centenary of University College, London, on June 23rd. The President, Sir D'Arcy Power, and Sir James Berry were appointed as representatives to be present at the coming celebration of the 1,300 anniversary of York Minster on July 1st.

Medical News.

The annual report presented to the meeting of the Hospital Saturday Fund on April 6th showed that the general fund amounted to £79,192. The collections and donations amounted to £77,037, a decrease of £1,713 on the previous year. The total sum received from all sources was £109,769. Though the receipts from business houses, workshops, and factories were affected by the general strike the fund had nearly regained its old position towards the end of the year. The sum of £59,061 had been awarded to hospitals, nursing homes, and other institutions as against £71,604 in 1925. At the conclusion of the meeting the chairman announced that at the present time the fund was £887 in advance of the corresponding period of last year.

A POST-GRADUATE course on diseases of the nervous system will be held at the National Hospital, Queen Square, W.C.1, from May 9th to July 15th. The general course will consist of clinical lectures and demonstrations, teaching in the out-patient department, and pathological lectures and demonstrations. A course of lectures on the anatomy and physiology of the nervous system and clinical demonstrations, chiefly on methods of examination of the nervous system, will also be given. Further particulars can be obtained on application to the secretary of the hospital.

THE Colyer Prize was founded by the Royal Society of Medicine in June, 1925, to commemorate the twenty-five years' service of Sir Frank Colyer as honorary curator of the Odontological Museum. The accumulated income of this fund (about £20) may be used every third year as a prize for the best original work in dental science completed during the previous five years, by a dental surgeon educated at any recognized dental school in Great Britain or Northern Ireland who has not been qualified to practise more than five years at the date of the award. Applications from candidates for the first award should be submitted not later than July 1st, 1928, together with a general account of their researches, both completed and in progress.

THE Fellowship of Medicine announces that a course of clinical and cystoscopic demonstrations will be given at the All Saints' Hospital from May 2nd to 28th; on each Wednesday during the four weeks a special lecture dealing with genito-urinary diseases will be delivered at 2 p.m. Also beginning on May 2nd and continuing for four weeks an afternoon course in psychological medicine will be held at the Maudsley Hospital. A four weeks' course in venereal diseases, including clinical instruction, will commence on May 2nd at the London Lock Hospital. On successive Wednesdays, from May 4th to 25th, Professor McIlroy will give lecture-demonstrations on ante-natal diagnosis and treatment at the Royal Free Hospital, at 5 p.m. An intensive course will be arranged at the Central London Throat, Nose and Ear Hospital from May 9th to 28th, comprising a clinical and an operative course, either of which may be taken separately. As the entry for the operative course is limited early application is desirable. From May 9th to July 15th there will be a course in neurology at the National Hospital, Queen Square. Two courses begin on May 16th at the Infants Hospital and the Hampstead General Hospital. The first course is open to those interested in infant welfare work as well as to post-graduates, and the second is primarily for general practitioners. Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

AMONG the Friday evening discourses to be given at the Royal Institution of Great Britain after Easter is one, on May 13th, by Sir Humphry Rolleston, Bt. Its title is "Concerning old age."

THE annual meeting of the members of the Auxiliary Royal Army Medical Corps Funds will be held at 11, Chandos Street, Cavendish Square, W.1, on Friday, April 29th, at 2.30 p.m., when the annual report and financial statement for the year ended December 31st, 1926, will be presented, and the officers and committee for the current year elected.

THE third lecture on the history of medicine will be given at the University of Durham College of Medicine, Newcastle-upon-Tyne, on Wednesday, April 20th, at 4.45 p.m., by Dr. Charles Singer of University College, London. Medical practitioners in the neighbourhood are invited to attend.

THE annual spring dinner of the Queen's University Belfast Club, London, will be held at the Connaught Rooms, Great Queen Street, W.C., on Thursday, April 21st, at 7.30 for 8 p.m., when Professor J. A. Lindsay, president of the club, will preside.

THE Board of Trade gives notice that representations have been made to it under Section 10 (5) of the Finance Act, 1926, regarding dial (acid di-allyl barbituric), elbon (cinnamoyl para-oxyphenylurea), integrators (planimeter type), R. lead acetate, lipoiodin (ethyl di-iodo brassidate), phytin (calcium magnesium inosite hexaphosphate), planimeters. Communications with the Board regarding these applications should be sent to the Principal Assistant Secretary, Industries and Manufactures Department, Board of Trade, Great George Street, S.W.1, within two months from the date of this notice (March 30th).

APPLICATIONS for the Dickinson Research Travelling Scholarship must be sent to Mr. Frank G. Hazell, Secretary of the Trustees, Manchester Royal Infirmary, by May 2nd. The scholarship of £300 is tenable for one year. Candidates must have graduated with distinction in medicine and surgery at the University of Manchester in any one of the three years immediately preceding the award.

THE Vocal Therapy Society exists to form ex service men into choirs, called the "King's Services Choirs," with a view to promoting the health of war-disabled men through speech, song, and efficient breathing. To the choirs started at the Star and Garter at Richmond, at Beckenham, and at Cheshunt, two new choirs have been added, one at the Ex-service Welfare Society's home in Nightingale Lane, and the "London Centre Choir," for men who have left hospital, in Osnaburgh Street. The report of the Society for 1925–26 records the success achieved at these centres in improving the health and nerves of disabled men. The late Sir Frederick Mott was one of the founders of the Society; and Sir James Dundas-Grant, Sir Bryan Donkin, Sir Robert Jones, and Sir George Makins are among the medical men interested in its work.

THE recipient of the Smith award of the Royal Institute of Public Health this year is Dr. J. R. Kaye, medical officer of health for the West Riding of Yorkshire. The award is made every third year to the medical officer of health considered to have done the most noteworthy work in the discharge of his official duties.

THE issue of the *Deutsche medizinische Wochenschrift* for April 1st contains appreciations of Lord Lister by Professor von Haberer of Graz and Dr. Leo Zumbusch of Liestal, and an autograph letter to the editor in which Lister expressed his regret that his state of health prevented him from contributing to the special number of the journal in honour of Robert Koch.

THE Minister of Public Instruction of the French Republic, having ratified the nomination made by the Council of the Faculty of Medicine of Strasbourg, Professor George H. F. Nuttall, F.R.S., of Cambridge, has been made Professor, *honoris causa*, of the University of Strasbourg.

THE second general congress of psychotherapy will be held at Bad Nauheim from April 27th to 30th.

ACCORDING to official statistics recently published there were 180 fatal cases of influenza in Holland last December.

DURING the academic year 1925–26, 1,242 diplomas of doctor of medicine were conferred by the following French faculties: Paris, 651; Lyons, 166; Bordeaux, 127; Montpellier, 113; Lille, 41; Toulouse, 40; Nancy, 33; Strasbourg, 30; Algiers, 30; and Beyrout, 11.

A JUGO-SLAV oto-neuro-ophthalmological society has recently been founded at Zagreb, with Professor Lapinsky as president.

A SOUTH American Anti-Cancer League has recently been founded at Buenos Aires.

A POST-GRADUATE course in modern methods of treatment will be held at Vienna from June 20th to July 2nd, and will be followed by special clinical instruction in classes. The subjects include endocrinology, the treatment of diabetes, surgical tuberculosis, and syphilis, and the use of *x* rays and radium. Further information may be obtained from Dr. A. Kronfeld, Porzellangasse 22, Vienna IX.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863, 9864* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

"D. H." asks for suggestions as to the treatment of tinnitus aurium in a man, aged 64, suffering from locomotor ataxy.

FEES FOR POST-MORTEM EXAMINATIONS.

"H. D."—Under the Coroners Act, 1926 (which comes into force on May 1st next), the following fees will be payable to medical practitioners:

(*a*) For attending to give evidence at any inquest whereat no *post-mortem* examination has been made by the practitioner, one and a half guineas for each day on which he is required to attend;

(*b*) For making a *post-mortem* examination of the body of the deceased and reporting the result thereof to the coroner, without attending to give evidence at any inquest, two guineas;

(*c*) For making a *post-mortem* examination of the body of the deceased and for attending to give evidence at an inquest on the body, three guineas for the first day and one and a half guineas for each subsequent day on which the practitioner is required to attend.

INCOME TAX.

Allowance for Wife's Assistance.

"D. L.'s" wife, a trained nurse, dispenses for him and gives him professional assistance in other ways. What allowance can he obtain?

*** Section 18 (2) of the Finance Act, 1920, provides for an addition to the normal (married) personal allowance of £225 where the total income includes earned income of the wife. The maximum addition is £45, or nine-tenths of that earned income. If, therefore, "D. L." were to pay his wife £36 as an assistant she would be assessable on £36, less £6 earned income relief = £30, but the £36 could be deducted as wages or salary in his professional account and nine-tenths of £36—say, £32—additional personal allowance claimed. It may perhaps be pointed out that no real benefit would accrue for 1927–28, as "D. L.'s" earnings would be assessable on the basis of his 1926 profits (when the payment was not being made) and his wife's salary on the actual amount for the year ending April 5th, 1928.

Letting of Unfurnished Rooms.

"J. H. B." refers to our answer to "Overtaxed" in the issue of March 26th and encloses a letter from his solicitors advising that he should continue to bring into his return the receipts obtained from letting unfurnished consulting-rooms.

*** It is, of course, true that taxpayers are called upon to make a return of all their income, but that income has to be calculated according to certain specified rules. In the case of rents derived from unfurnished rooms, there is, in our opinion, no need to regard them as chargeable other than under Schedule A. When the gross annual value of the premises in question was determined it may be presumed that their suitability for such a purpose entered into the estimate, or, if the premises are held on a lease for full rent, that the assessment was made accordingly. Therefore, our correspondent appears to be entitled to regard his liability in respect of the rents for unfurnished rooms as covered by the assessment under Schedule A, which may or may not be liable to increase. One point should perhaps be mentioned: the amount of the rents so obtained would be one factor, amongst others, in determining what fraction of the total value should be deducted as the equivalent of rent paid for that portion of the premises occupied by himself for professional purposes—if he deducts the whole, then obviously he must bring the rents into the account of his earnings.

LETTERS, NOTES, ETC.

"THE LONDON CLINIC."

We have received for publication the following letter signed by Drs. L. D. Bailey, J. F. Carter Braine, E. P. Cumberbatch, S. L. Higgs, D. Hubble (resident medical officer), Reginald Jewesbury, G. Murray Levick (honorary medical director), Stanley Melville, and C. A. Robinson; together with Lord Dawson of Penn and Sir Thomas Horder (members of the Advisory Committee):

"In view of certain publicity which has recently been given to the London Clinic (founded and maintained by the British Humane Association), we wish it to be known that we have severed our connexion with that body."

BOVINE TUBERCULOSIS: GUERNSEY'S GOOD RECORD.

DR. HY. DRAPER BISHOP (M.O.H. Guernsey) writes: The very low incidence of tuberculosis amongst the cattle of Guernsey is, I believe, fairly well known, if not on this side of the Atlantic, at any rate on the other. During the years 1925 and 1926 the number of cattle tuberculin-tested was 1,950; of this number there was one reactor only.

OPIUM SMOKE AS AN ANAESTHETIC.

IN a note by Dr. G. L. Deshmukh of Bombay, published in the JOURNAL of February 26th (p. 410), he described how, an ordinary anaesthetic not being available, he was able, without inflicting pain, to sew up a wound in a patient who had been given opium to smoke. Dr. W. Macewen of Glasgow inquires how opium is smoked and whether its use could be recommended as an anaesthetic.

*** The method of preparing opium for smoking is described in the *Encyclopaedia Britannica* (eleventh edition) by way of extracts from published statements by Mr. Hugh M'Callum (Government Analyst, Hong-Kong) and Mr. Theo. Samoson (of Canton). The quotations are too long to reproduce here. Briefly it comes to this: the opium is of a treacly consistency and is picked up and twisted on to a sharp-pointed dipper. With acquired dexterity the smoker introduces the pellet of opium into the centre of the bowl of a pipe of special construction. He puts the stem to his lips and holds the bowl over a lamp. The heat causes the opium to frizzle, and the smoker

takes three or four long pulls, inhaling the smoke and afterwards expelling it through nose and mouth. He then prepares another pipe, and so on until he has obtained the effect he desires; the preparation of each pipe takes from five to ten minutes, and the actual smoking about thirty seconds. In China the kind of opium used for smoking is called chundu, and should contain the alkaloids morphine, codeine, and narceine. When smoked it is supposed that the morphine more or less disappears and that some other product of a more pleasing taste is formed during combustion, for the bitterness of morphine is lost in smoking. We are advised that, in people who are accustomed to opium smoking, small operations would be possible under it, but that to introduce it here, when there are other better things to be found, would be foolish. The use of some anaesthetic to ease pain goes back to a remote past, for Homer speaks of nepenthe as used amongst the Greeks, and Herodotus states that the Scythians used to inhale the smoke of burning herbs when operations were being performed; these herbs, it is believed, were a kind of hemp. A Chinese surgeon, Hoa-Tho, used hemp for his surgery. Dioscorides and Pliny, it may be remembered, spoke of the use as an anaesthetic of mandragora, which is said to contain an alkaloid having an action resembling atropine.

A FATAL CASE OF SALVARSAN POISONING.

DR. G. P. F. ALLEN (Kingston, Jamaica) writes: Dr. T. J. Evans's memorandum in the JOURNAL of January 15th (p. 99) on acute yellow atrophy of the liver recalled to my mind a fatal case of salvarsan poisoning which came under my care some years ago. A girl, aged 15, was undergoing arsenical treatment for syphilis in the out-patient department of the Kingston Public Hospital, Jamaica. She became suddenly ill on returning home after the second or third injection, and I was called to see her. I found her lying in bed speechless. She was profoundly prostrated and vomited bile at frequent intervals. The temperature was 98° F., pulse 93; the respirations were sighing. The eyes were staring and the conjunctiva bile-stained. The liver and spleen were slightly tender, but neither organ was enlarged. Next day the patient had passed into a state of noisy delirium, with muscles twitching. The pulse was soft and feeble, and the rate had increased to 110. The urine was voided in the bed and left a bright yellow stain; none was obtained for examination. Death occurred shortly. A necropsy could not be performed, but all the facts seemed to suggest that arsenical degeneration of the liver was the cause of death.

MIGRAINE AND ACETONURIA.

DR. JOHN A. GRAHAM (Bethulie, O.F.S., South Africa) writes: I have been a sufferer from migraine since my seventh year, although for many years now I have been able to recognize the prodromata and to abort the attack. Warning signs are great drowsiness without real sleep, trouble in eyesight, difficulty in focusing, etc., and very often not diarrhoea but passage of frequent small motions. When these symptoms appear, or any of them, I find that a couple of grains of calomel, repeated in three or four hours if there is no improvement, or a grain of calomel with a laxative vegetable tabloid (B. W.), prevents the attack from developing. If the attack appears without such warning, as occasionally happens, starvation for the best part of the day, with calomel, and repeated doses of caffeine and phenacetin, effect a cure. But as for glucose, I cannot quite see the rationale. Occasionally there is undoubted acidosis and the headache persists, when a big dose—a couple of drachms—of sodium bicarbonate clears up the condition. Sugar, I think, is one of the things that bring on an attack. I am very fond of sweets, but if I have more than three or four chocolates an attack of migraine is certain to follow. So that the problem remains, as Dr. Allison suggests, whether sugar, as such, is a cause of migraine, or whether it is so in a roundabout fashion, via malassimilation, with formation of acids and acetone.

RELATIVE SHORTNESS OF CORD: RETENTION OF CHORION.

DR. C. J. HILL AITKEN (Kilnhurst, near Rotherham) writes: The tediousness of a multipara's labour was explained when the child was born—very blue and with the cord coiled round the neck and round an arm. Half an hour later, the patient having had a good pain, gentle pressure on the fundus uteri, with the patient's effort, finished the third stage. Examination of the placenta showed marked absence of the chorion, which came away six days later. Early separation of the placenta is said to be liable to occur with a short cord. In this case the placenta had been separated from the chorion. It is a problem whether this separation took place while the child was passing through the passages or was caused by the attendant while disentangling the cord. Although retention of the chorion is possibly not very dangerous, it is certainly disquieting. It might be wise in cases such as the above to cut the cord before freeing the child.

CRÉSOPIRINE.

DR. J. LANDMAN (London, W.1) writes with reference to the paragraph under this heading published on April 2nd (p. 635) to state that in 1914 Messrs. Howards and Sons made under his direction a preparation having the same chemical constitution as the substance prepared by Professors Carrière and Gérard in 1926. Dr. Landman made extensive clinical trials, but was unable to satisfy himself that the substance had any clinical advantage over aspirin. Messrs. Howards made it up in 3-grain tablets, and still have a stock on hand.

THE MEDIZINER.

DR. LIEK, in a little book on the doctor and his vocation,[1] deals in a somewhat discursive manner with questions which from time to time give passing food for thought in the daily round of medical practice. What are we to understand by the ideal physician? Is sickness insurance a good thing in all its aspects? Is the purely scientific spirit looming too largely in our medical curricula and among our practitioners? What are we to think of pseudo-medicine and quackery? How can we best express the relationship between doctor and patient? Questions such as these, which probably pass through the mind of every practitioner at one time or another without receiving any very definite answers, are touched upon in this volume, which, having reached a second edition, presumably supplies a need. Possibly its popularity depends to some extent on its subtitle, "Thoughts of a heretic," for a little heresy is attractive to many minds, especially those of a highly sympathetic cast. The author is mainly disturbed by the prevalence of what he calls the "mediziner"—a disagreeable character for whom we have no corresponding name in our language, because no doubt we have not got such persons. He stands at the opposite pole to Dr. Liek's ideal physician. The mediziner is, if we understand Dr. Liek aright, one whose humanity has been blighted by science, falsely so called. The genus appears to consist of two species: in one the practitioner is so obsessed with his science that the patient disappears as such and assumes the character of a mere pathological lesion; in the other the notion of patient is retained, but there is no recognition of his humanity. An example of the first type is described as an elderly man of somewhat rugged exterior and manner, who has done much to forward operative gynaecology, who can boast of a number of important contributions to the journals, is a brilliant operator, an experienced gynaecologist, a recognized scientist; but every woman who comes to his clinic, whatever may be the cause, is forthwith placed on the table and operated upon. On one occasion Dr. Liek inquired what a woman looked like who did not want operating upon: "there are none such here," was the reply. In this type we have no difficulty in recognizing that professional complaint which goes under the name of "furor operativus." Of the second type we are given a graphic picture, evidently drawn, like the former, from the life. He is a good surgeon, a man of comprehensive knowledge, a born scientist whose name will live in the annals of medicine, a skilful technician, extraordinarily careful and thorough in the investigation of his cases, never performing an unnecessary operation, but brusque to a degree in his manner to his patients, and of a forbidding silence. So far as his patients are concerned he is a surgeon and nothing else, purveying surgery as the grocer purveys groceries, with a purely mechanical and materialistic outlook, not indeed denying the existence of a soul in his patients, but ignoring it. Yet in his family circle and among his friends this forbidding person is humorous, jovial, and sympathetic. The author's humane nature revolts against such inhuman types, and we are not surprised to learn that his ideal physician is none other than the country practitioner, with his genial manners and his interest in his patient's dogs and fishing tackle and babies.

SUN SPOTS AND SUDDEN DEATH.

THE increased number of sudden deaths reported in 1926 and the fact that such fatalities occur in groups at irregular intervals is thought by Dr. M. Faure of La Malou to be due to sun spots. During 1922, with Drs. J. Vallot and G. Sardou, he submitted evidence that the passage of these spots over the central solar meridian coincides with the appearance or recurrence of acute crises in various chronic illnesses. At a recent meeting of the Académie de Médecine Dr. Faure returned to this subject, and stated that, whereas an average of thirteen sudden deaths occurred during 100 days on which the solar surface was clear, the mortality rose to twenty-six for another 100 days on which sun spots were visible. He explains this coincidence of solar and clinical disturbances as being due to an interference with "electro-magnetic" radiations, which results in the upsetting of the controlling mechanism of the physical body, comparable with the effects these spots also produce on telegraphic and telephonic apparatus. In patients whose constitutions are so affected by disease as to approach the critical point, when outward signs are manifested an added disturbance of this kind might be expected to produce a response out of proportion to the strength of the stimulus itself. The increase in the number of sudden deaths during 1926 is, therefore, held by Dr. Faure to be directly associated with the occurrence in this year of numerous sun spots. We must leave it to our readers to determine what importance, if any, attaches to Dr. Faure's theory.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 37, 38, 39, 42, 43, and 44 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 122.

An Address
ON
THE EPIDEMIOLOGY AND PATHOLOGY OF POLIOMYELITIS.

DELIVERED BEFORE THE PORTSMOUTH DIVISION OF THE BRITISH MEDICAL ASSOCIATION,

BY

JAMES COLLIER, M.D., F.R.C.P.,
PHYSICIAN AND LECTURER IN MEDICINE, ST. GEORGE'S HOSPITAL, LONDON.

THE word "poliomyelitis" nowadays is restricted to the clinical and pathological results of a definite specific infection of the anatomy, though the part invaded may be the brain, the cerebellum, the spinal cord, or the peripheral nerves, or any combination of these structures. The term "polio-encephalitis" is no longer used, nor do we speak of "anterior poliomyelitis," nor of "acute poliomyelitis," nor of "chronic poliomyelitis," but simply of "*poliomyelitis*," to denote this peculiar specific fever which has the incidence of its effects chiefly upon the nervous system.

This malady has been incident upon humanity since very early times, as the references in classic literature to "he *that hath a withered limb*" will tell you, or the many portrayals of the deformities produced by the malady in early sculpture and mediæval paintings will show you, but never until our lifetime has it been known as a pestilence which, affecting one small district, in a few years claimed 50,000 victims; nor as a plague which in three short months could leave behind it 5,000 dead and 12,000 paralysed, as it did in New York State in 1916; nor as a swift scourge which, lighting upon the little village of Stoke Rivers in Devonshire, could lay low in a few days 45 persons out of a total population of 119.

These events are new to the world of medicine in which we have lived, for when I joined our profession poliomyelitis was not described as an infectious disease, though an epidemic of 11 cases in one village had been recorded as early as 1843 by Colmar. There were other small community outbreaks in my early years, but it was an outbreak of 1,500 cases in Sweden in 1905 which led to the most important discoveries upon the nature of poliomyelitis. On account of the geographical nature of Sweden and the distribution of its population in small village communities with few lines of communication, the spread of the infection was comparatively easy to trace, and Wickman, who investigated this epidemic, was able to prove that the disease only travelled along the lines of human communication, that it would not cross from village to village over a ravine, even though these villages were only a hundred yards apart, unless there was a road or a bridge or a boat by which human beings could pass. Moreover, he proved that whenever infection spread to a fresh village, someone had visited that village from a definitely infected village. That person was obviously one who was not sick with the disease, nor was he one who subsequently became affected.

Wickman therefore proved the very important facts that poliomyelitis is conveyed by human contact only, and usually by those who do not suffer with symptoms of the malady. He proved the importance of carrier infection. Wickman made very important clinical observations as well. He found eight different types of illness with nervous symptoms common during this epidemic, in addition to many cases of fever in which there were no nervous symptoms. Some of these were very unlike the usually accepted clinical picture of poliomyelitis. Many years before, however, Strumpell and others had stated their belief that acute encephalitis was really poliomyelitis affecting the brain, and Wickman boldly asserted that all the dissimilar illnesses observed by him in the Swedish epidemic were manifestations of one and the same infection; and his assertion was before very long a proved fact. He had able pathologists to help him, and with the advent of the American epidemics great advance was made by Landsteiner and Popper, by Flexner and Lewis, by Taylor and Amos, and by Levaditi.

These workers have succeeded in infecting monkeys with the disease by means of emulsions of the spinal cord from a fatal case, and by means of washings from the nasopharynx of any person recently ill with the disease. The infection can be attained by injecting the virus subcutaneously, or into any of the serous cavities, or into a nerve trunk, and most certainly of all into the central nervous system; but, curiously, intravenous injection will never produce the disease, for the blood seems to destroy the virus at once. They also communicated the disease by smearing the virus on any of the mucous surfaces, or rubbing it upon the fingers of the monkey or upon the bars of his cage so that he could contaminate his own mucous membranes. The malady can be propagated through an endless strain of monkeys, with the production in each of a fatal disease commencing with pyrexia and general illness and terminating with paralysis. Very nearly the same changes are found *post mortem* as are found in human cases, so that the clinical and histological picture in man and in the monkey may be said to be identical.

Investigating all the members of a household in which there was a case of poliomyelitis in the acute stage, Kling, Pettersen, and Wernstedt found that they could obtain the virus from the nasopharynges of 30 per cent. of the non-affected inmates, and therefore proved the important fact that there are always three other people who carry, and are therefore able to transmit the malady, for every one who suffers. As I shall try to prove, the disease is never transmitted by the one who is suffering from it, but only by the carriers; this has a very wide bearing when dealing with the malady from a public health point of view.

The virus of poliomyelitis thus obtained resists desiccation for twenty-four days, and a mixture of 50 per cent. glycerin, which kills most bacteria, has no effect whatever upon its potency, and advantage is taken of this fact to prepare the virus uncontaminated. Nor is it affected by 5 per cent. carbolic acid; but it is instantly rendered impotent by hydrogen peroxide or by a 1 per cent. solution of permanganate. The virus will pass through two inches of solid porcelain under pressure, which proves that, if particulate, the organism is very small. It is therefore known as a "filter passer." But if this virus is passed again and again through a fresh porcelain filter it becomes less and less potent with each passage, which suggests that the virus is particulate and only just small enough to pass with difficulty the pores of the filter. Actually the organism is said to be a very small round thing, which has been called a globoid, of which fifty would lie easily on the surface of a red blood corpuscle. It is claimed that this globoid virus can be cultivated upon Noguchi's medium—a mixture of peritoneal fluid and rabbit's kidney—and that the globoids can be seen *in situ* in the lesions in every case of poliomyelitis.

This virus is communicated from person to person by "droplet infection," which means that whenever I speak to one of you—say at a yard's distance—I spray you continuously with droplets from the surface of my respiratory passage; and if I am a carrier of poliomyelitis I spray you with the virus, some of which is likely to reach your respiratory mucous membrane when you are inspiring. In this untoward event one of three things must happen to you as the result of your receiving the virus: either (1) you develop the disease, or (2) you become a carrier and capable of handing the infection on to another person, or (3) you become immune relatively or absolutely. Whether you become a case, a carrier, or an immune person will depend, first, upon the dose of the virus which you receive from me per unit of time, secondly, upon your personal power of destroying that virus; and thirdly, upon how quickly the protein content of the virus stimulates or depresses your immunizing mechanism. These two last factors being of average intensity the result will depend upon how far I am from you when I spray you with the virus.

Now if a person develops the disease, the virus which is multiplying upon his respiratory mucous membrane seems at once to lose its virulence, so that a case of poliomyelitis does not seem able to convey the infection to another

person, though the virus may be still found upon the mucous surfaces for about a fortnight.

If a person becomes a carrier the virus is likely to become more virulent for a time, but soon it loses its potency and the person ceases to be a carrier in a fortnight or so. There are no chronic carriers as there are in connexion with diphtheria and epidemic meningitis.

It seems, then, to be a recent carrier who transmits and spreads the disease, and a chain of carriers who carry on the infection during those times when poliomyelitis is not about and give rise occasionally to those cases of poliomyelitis which are called the "sporadic cases," as distinguished from the "epidemic cases."

I want it very clearly to be apprehended that though the virus can be obtained from the mucous membrane of cases for some days after the disease has appeared, and monkeys can be inoculated with the disease from this virus, that does not mean for one moment that a patient even in the early days of his illness can deliver an infective dose of the virus to another person. There is strong evidence that a case of poliomyelitis is not infectious, and that a carrier, especially a recent carrier, may be very infectious. As this question as to whether poliomyelitis is infectious from case to case, or not, is one of paramount importance, I will state the evidence briefly. Let me in the first place give the story of a carrier. One day at the market town a farmer from a country village sold a horse to another farmer who lived some twenty miles away, and as part of his contract had to deliver the horse at the farm of the purchaser. He started from home leaving his child ill with poliomyelitis. He took the midday meal with the purchaser and sat between two of the children at table. Within forty-eight hours both of these children were ill with poliomyelitis and a few days later their mother and another child were stricken with the disease. Here were four members of one household stricken by one short visit of a carrier, with no possible source of infection from elsewhere. Probably, too, this father had infected his own child, for adults are often carriers.

Such instances as the story of the farmer just recited could be multiplied indefinitely—the Swedish epidemics teemed with them. But when we come to seek for evidence of case-to-case infection we have to search the literature carefully for any event put forward as an example. And when the few recorded instances are examined it is found in every case that it is one child of a household who is said to have infected other members of the household or other contacts, and we know full well that whenever a case of poliomyelitis appears, and as soon as it appears, 30 per cent. of the members of that household are already carriers and provedly capable of infecting; and in any case it is at least three chances to one against the sufferer from poliomyelitis being the infector of others, even if he were capable of infecting, which I submit he is not.

The only real test that would prove a developed case to be capable of infecting others would be to remove the patient in the early pyrexial stage and place him in a community of susceptibles. Put him in the children's ward of a hospital and see what happens. I have seen this done, as all of you have seen it done, on scores of occasions since we first entered hospital, yet there is not one single record in the whole of medical literature of such a patient transmitting the disease to another child in hospital. Dr. Batten, who had thirty years' experience of the Great Ormond Street Hospital for Sick Children, went into this point very carefully in the Lumleian Lectures for 1916, and vouched that no case had ever occurred in that hospital, where acute cases of poliomyelitis were frequently admitted into the general wards. I think that this evidence is very conclusive, but I know how difficult it is to get the public to accept it. In the lay mind one case of infectious disease must always arise from another similar case, and in deference to such an opinion it is wiser to isolate patients.

I would like to submit to you my opinion that when an epidemic of poliomyelitis occurs in a community it is preceded by a carrier epidemic in which for a time no cases occur but many carriers are made, and that, with the increasing advent of carrier infection to susceptibles, the virulence of the infection is raised and at last definite cases occur. By this time the infection is all through the community, and doubtless much immunization has already occurred. This is probably the reason why poliomyelitis seems in its epidemic form to avoid schools, institutions, and towns, and densely populated districts where there is much daily mixing of the community, and to prefer sparsely populated country districts, where communication between house and house and from village to village is more restricted. It seems to me to be the only explanation of the occurrence of the first fifteen cases in an epidemic on the same day in fifteen widely separated places of one countryside, as happened in one of the English epidemics. Such a preceding carrier epidemic best explains the curve of incidence in an epidemic, with its rapid blaze, high peak, and rapid fall, all the cases occurring within a few days and then no more cases. All the cases at Broadstairs, for example, occurred between October 15th and November 9th, and there were many more cases among the general population than in the schools.

Now if this description which I have put forward is just it follows that when a case of poliomyelitis occurs in a semi-isolated community such as a school which has been assembled, say, for several weeks, there has already been a carrier outbreak going on for some time, and all the boys are already infected as cases or carriers or they are immune. The actual cases are not infectious, and all the damage that can be done has been done so far as the boys are concerned. Therefore keep them together, and the epidemic will die out with no further trouble than would have occurred in any case. But before the epidemic has died out do not disband the carriers, by whom alone infection can be spread, and scatter them over the country for the continuance of the disease.

The virus of poliomyelitis has never been found except upon the mucous surfaces or within the nervous system. It has been proved to be capable of passing through the whole length of the intestine with undiminished potency, and therefore any part of the respiratory and alimentary mucosa may be the point of advent of the poison to the nervous system, and it seems likely that the point of advent may determine which part of the nervous system is chiefly attacked. When once within the nervous system the virus seems to travel fairly readily.

It follows from these facts, and from the fact that the blood stream will not convey the virus but seems to destroy it at once, that the general swelling and parenchymatous degeneration which is found in the lymphoid tissue of the body generally, and in the liver and spleen, must be the result of some toxin produced by the virus.

The virus gains access to the nervous system by one path only, and that is by travelling along the nerves, either along the perineural lymphatics or along the axon, just as the virus of rabies does or as do the toxins of tetanus and diphtheria. It has recently been proved that the path is by the anterior roots only—there seems to be a trap at the posterior root ganglia which prevents access by the posterior roots; for if the anterior roots be divided injection of any of these poisons into the corresponding nerve is not followed by infection, whereas if the posterior root be divided infection takes place as in the intact animal. This may be the explanation why the damage in poliomyelitis falls most heavily upon the ventral horns of the spinal cord, which are in close connexion with the anterior roots.

The effect of the virus upon the nervous system is twofold. First there is a poisoning of the nerve elements which destroys their function. This poisoning may be recovered from, or it may end in degeneration of the nerve element. It is the recovery from such a poisoning effect which is responsible for the rapid clearing up of the paralysis, or of part of the paralysis, which one so often sees in the first week or two of the illness. Secondly, there is a local inflammatory reaction, often so intense as to lead to actual necrosis of the affected region and frequently associated with many small haemorrhages. The actual inflammatory process is the outpouring of lymphocytes in very large numbers round the blood vessels with marked oedema of the tissues, and, so far, it is exactly like the lesion of lethargic encephalitis and the lesion of syphilis, but in poliomyelitis there is always a considerable number

of polymorph cells mixed with the lymphocytes, which will at once distinguish this lesion from that of syphilis and lethargic encephalitis.

Whenever the inflammatory lesion reaches the surface of the nervous system and the meninges there will be outpouring of cells into the cerebro-spinal fluid and a recognizable change in this fluid, immensely important in diagnosis, together with signs of meningitis. Now as meningitic symptoms, such as headache, head retraction, diplopia, nystagmus, vomiting, and pains in the back and limbs with pyrexia, are among the commonest of symptoms of all cases of poliomyelitis, especially when this disease is epidemic, it will interest you to know that from the first symptom of the disease the cerebro-spinal fluid of poliomyelitis is highly characteristic, and that a lumbar puncture will not only relieve the headache and pains and possibly lessen the severity of the disease, but it will help you to a diagnosis in at least 98 per cent. of the cases. There is an increase in the protein content, and often a fine spider-web clot forms on standing for a few moments. The chlorides are normal: this will at once distinguish it from tuberculous meningitis, in which the chlorides are characteristically subnormal. The sugar is normal: this will at once distinguish it from all forms of bacterial meningitis, for in every one of these the sugar is below normal. There is an increase in the cells, which may be lymphocytes or polymorphs or both. The culture is sterile.

There is only one other acute pyrexial disease which gives a fluid sometimes like this, and that is lethargic encephalitis, but I wish you especially to remember that the polymorph cells are never found in the cerebro-spinal fluid of lethargic encephalitis, and when these are present the diagnosis must be that of poliomyelitis.

CONGENITAL IDIOPATHIC DILATATION OF THE COLON TREATED BY STRETCHING OF THE PELVI-RECTAL SPHINCTER.

BY

ANDREW FULLERTON, C.B., C.M.G.,

PRESIDENT, ROYAL COLLEGE OF SURGEONS IN IRELAND; PROFESSOR OF SURGERY, QUEEN'S UNIVERSITY, BELFAST.

CONGENITAL idiopathic dilatation of the colon (Hirschsprung's disease or megalocolon) is described in textbooks as an enormous dilatation of the colon with hypertrophy of its walls, affecting all or part of the large intestine. The parts most frequently affected are the descending, iliac, and pelvic colons.

The object of the present note is to advocate the trial of a method of treatment which aims at dealing with the cause. L. E. Barrington-Ward[1] in 1914 gave a full account of the disease and supplied a list of thirteen different views as to its causation, under the headings of "Mechanical," "Neuropathic," "Inflammatory," and "Congenital." He referred to *post-mortem* examinations made at Great Ormond Street Children's Hospital on nineteen undoubted cases, in all of which the sigmoid colon was hypertrophied. In ten of these cases the hypertrophy also involved the rectum as far down as the anal canal. In no case was any mechanical obstruction to be found, though in one the bowel was said to be kinked as it turned into the pelvis. After discussing the various theories he states:

"The theory that best explains this series of cases is as follows: There is a congenital abnormality in the lower end of the hind gut which takes the form of a muscular hyperplasia. It usually involves the rectum and extends for a varying distance up the pelvic and iliac colon. . . . In some cases there is definite localization of the change (as in three cases described) where the hyperplasia has affected a segment of the intestine chiefly. . . . The physiological functions of the intestine are in abeyance, a block is produced, and the bowel *behind*, for a varying distance . . . dilates and hypertrophies."

A. F. Hurst[2] believes that this affection is due to achalasia, or absence of the normal relaxation of the circular muscular fibres found at the pelvi-rectal flexure, or of the anal sphincter. He holds that there is a close similarity between what is known as cardiospasm (or, as he terms it, achalasia of the cardia) and megalocolon.

A. J. Walton,[3] in discussing the surgical treatment of cardiospasm, describes fourteen cases in which he adopted the method suggested by Mikulicz—that is, opening the stomach and digitally stretching the lower constricted portion of the oesophagus. The result in these fourteen cases was entirely satisfactory.

THE PELVI-RECTAL SPHINCTER.

The lower part of the large bowel consists functionally of two parts, a colic part and a rectal part, and between these there is a functional junction. In the dead body, hardened with carbolic acid and formalin, the functional tract shows considerable variety in form and appearance. As a rule, however, it is a definitely contracted region of the bowel, always empty, and in strong contrast with the part above, and, to a less degree, with the part below.

Under normal conditions the faeces do not at once pass through this tract, but collect in the movable pelvic colon above until just before defaecation, when they are discharged into the fixed rectum below. Between the two parts there is an angulation, especially in the erect position. W. J. Mayo[4] has shown that the mucous membrane of the last two inches of the colon is disposed in longitudinal folds, contrasting with the circular arrangement in the rest of the colon. This favours the suggestion that the segment referred to is normally obliterated by a sphincteric action of its circular muscular fibres. A similar arrangement is seen in the abdominal portion of the oesophagus, and in the pyloric end of the stomach.

It has not yet been shown that there is developed in the pelvi-rectal tract a sphincter comparable with that found at the pylorus, but over its whole length, which varies from half an inch to two inches, it is believed that there is a sphincteric action of the circular muscular fibres sufficient to obliterate the lumen and to withstand the weight of the contents above. The lumen becomes patent when the circular muscular fibres of this tract relax. Interest is being taken in this matter at Queen's University, and Professor Walmsley believes it is possible to demonstrate a more definite sphincter in the foetus.

Recently I had the opportunity of examining the rectum of a woman, aged 28, in whom I had, six months previously, excised the entire colon with a few inches of the terminal ileum, for multiple papillomata of the former. The junction of the ileum with the lower bowel was made about eight inches from the anus—that is, well above the pelvi-rectal tract. I expected in this patient that the rectum would be full of liquid faeces, but it was empty, and it was only on passing a sigmoidoscope some distance up that semifluid faeces began to escape. The presence of an efficient pelvi-rectal sphincter may be assumed in this case. The patient can retain faeces for many hours at a time, the bowels acting from two to five times in the twenty-four hours.

TREATMENT OF MEGALOCOLON.

Medical.

By means of enemata, massage of the colon, liquid paraffin, and aperients, a certain proportion of cases may be benefited, but the mortality is very large, some authors placing it as high as 74 per cent.

Surgical.

Barrington-Ward, in the paper referred to, thinks that a fair estimate of the surgical mortality would be about 36 per cent. He considers that the ideal form of treatment is the removal of the whole of the affected bowel down to the anus. He advocates, in young children, operation in two stages. At the first operation the ileum is divided and implanted as low down in the rectum as possible. Some months later, when the child's strength has increased, the large bowel above the anastomosis is excised. Treatment on these lines has been carried out by Arbuthnot Lane and others with success.

An operation of the magnitude of colectomy in a debilitated child, even if performed in two stages, is a terribly severe measure, and would undoubtedly, if universally adopted, be attended with a high rate of mortality. Moreover, it seems unscientific and incorrect to remove a hypertrophied organ striving to overcome an obstruction, instead of seeking out and dealing, if possible, with the cause.

If Hurst is correct in his assumption that the block in this disease is due to pelvi-rectal or anal achalasia, stretching of the pelvi-rectal sphincter, and, less obviously, of the anal sphincter, ought to relieve the obstruction, just as stretching of the cardiac sphincter has relieved the obstruction in so-called idiopathic dilatation of the oesophagus, or cardiospasm. The following case seems to support this contention.

A boy, aged 2 years and 4 months, was admitted to the wards of the Belfast Hospital for Sick Children, under the care of my colleague Dr. Leathem, on November 11th, 1926, with the following history. He had been breast-fed, but from birth had been constipated, and from the age of 9 months the constipation had become more troublesome. Enemata, paraffin, and other measures were required to secure an action of the bowels. Gradually the abdomen became more and more distended, and the child had recently begun to lose colour and weight. For two days before admission he had complained of abdominal pain, which was attended with persistent vomiting.

Condition on Admission.

The child was pale and drowsy, and vomited dark coffee-ground material at short intervals. The abdomen was much distended, and measured 32½ inches in circumference at the level of the umbilicus. Peristaltic waves were visible, and a "ladder pattern" could be produced by abdominal palpation. Pain came on in spasms, and was associated with a desire to vomit. The distension involved the whole area of the abdomen, which was tympanitic on percussion. I saw the child on November 15th, at the request of Dr. Leathem, who was very much opposed to the adoption of any heroic surgical measures. Examination by the finger of the anus, the anal canal, and the lower part of the rectum disclosed no abnormality, but about the level of the sacral promontory the examining finger encountered an encircling band, apparently about a quarter of an inch in breadth, constricting the bowel.

Operation.

The child was immediately anaesthetized, and, as a preliminary, the sphincter ani was gradually and carefully stretched. When this had been accomplished the index finger was inserted into the narrowed area just mentioned, and pushed up so as to dilate the constriction. The middle finger was then also introduced, and further stretching was effected. Finally, both index fingers were inserted until the last phalanx of each rested above the band, and by pulling upon the latter the upper bowel was partially invaginated into the lower. It was now possible to separate the fingers and dilate more widely still. Great care was taken during these manipulations to avoid rupture of muscle or damage to mucous membrane.

After-History.

The child was put back to bed, and during the next twenty-four hours large quantities of faecal matter were brought away by enemata. Vomiting ceased at once, and the child became quite comfortable. The enemata were continued with success, and the child was again examined under an anaesthetic on November 27th, twelve days after the first examination. It was now possible to pass a sigmoidoscope right up into the pelvic colon, where it could be felt on abdominal palpation. The mucous membrane of the bowel was red and inflamed, but no accumulation of faeces was seen.

Introduction of Dilating Bag.

To maintain the dilatation already effected a pear-shaped rubber bag, with a diameter of one and a half inches at its broadest part, was inserted and passed beyond the band, which was still palpable. The bag was then distended with water, and the tube leading from its narrow end was wound spirally round a glass rod laid across the child's buttocks, and fixed in position. (See Fig. 1.) The nurse was instructed to rotate the glass rod at intervals so as to increase the tension of the rubber tube, and thus maintain steady pressure on the constricted portion of bowel. When the bag was in position a finger was introduced into the rectum, and it was found that a slight degree of invagination of the upper bowel into the lower was being produced by the drag on the rubber bag. This is shown in Fig. 1. Later, the water in the bag was replaced by sodium iodide solution, and an *x*-ray photograph was taken. The skiagram (Fig. 2) shows the position of the bag in the pelvis, the site of the constriction being indicated by an indentation below the broad end. The drawing in Fig. 1 is intended to be a reconstruction of the parts, from the *x*-ray photograph. The bag is represented as lying in the bowel, and the position of the constriction is shown. The bag was passed spontaneously twenty-four hours after its insertion. An opaque enema was given on December 16th—that is, about a month after operation—and the *x*-ray photograph shows the enormous dilatation of the colon, the anal canal, and what appears to be the site of the pelvi-rectal sphincter. (Fig. 3.) A further stretching was carried out on January 22nd, 1927, as a precautionary measure.

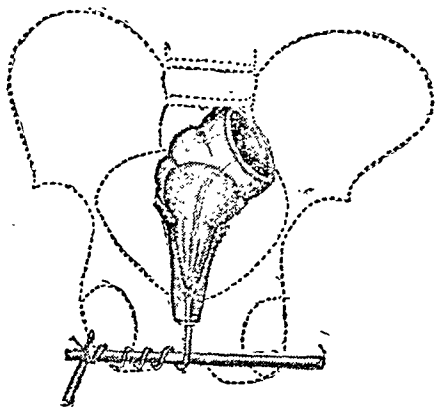

FIG. 1.—Drawing to show position of rubber bag in bowel and situation of pelvi-rectal sphincter.

The subsequent progress of the case has been extremely gratifying. The circumference of the abdomen has been reduced from 32½ in. to 18½ in., though it varies a little from time to time. The bowels respond well to aperients and enemata, and frequently act without assistance. The abdomen appears normal on inspection. The thickened colon can, however, be palpated along its entire length, and can be felt to contract, especially after massage. The patient's condition is excellent. He has put on weight, his appetite is good, and his colour is that of a healthy boy. He was discharged from hospital on February 5th, not quite three months after admission, having been detained longer than was necessary, in order that his progress might be followed. He is now (April 16th) in perfect health, and his bowels act daily without aperients.

FIG. 2.—*X*-ray photograph of dilating bag in position.

FIG. 3.—*X*-ray photograph after an opaque enema (taken a month after operating).

SUMMARY.

This case concerns a boy, aged 2 years and 4 months, with typical Hirschsprung's disease. Treatment was carried out on the hypothesis that there was achalasia of the pelvi-rectal sphincter. The treatment consisted in stretching the sphincter ani and the pelvi-rectal sphincter.

The result up to date has been satisfactory. It is suggested that this line of treatment might be tried before resorting to grave surgical procedures. Should it be impossible to reach the sphincter from the anus an attempt might be made after laparotomy to stretch or divide the contracted muscular fibres from the abdomen.

My thanks are due to Professor Walmsley for the description of the pelvi-rectal sphincter, to Miss Rea for the drawing, to Dr. M. Robinson, house-surgeon at the hospital, for his notes of the case, and to the *x*-ray department of the Royal Victoria Hospital for its help and interest in the case.

TESTING FOR OCCULT BLOOD IN FAECES.

A STUDY OF ALLEGED FALLACIES.

BY

A. G. OGILVIE, M.B., B.S.

(From the Pathological Department, Royal Victoria Infirmary, Newcastle-on-Tyne.)

THE great clinical value of a reliable test for occult blood in the faeces is generally recognized, but there is divergence of opinion as to what constitutes a reliable result. A number of fallacies have been alleged to occur, the chief among them being due to diet, and until comparatively recently it was generally accepted that the tests were valueless unless performed under special conditions.

The great majority of British observers still hold this view. Coope,[1] Hurst,[2] Beaumont and Dodds,[3] and others rigidly exclude from the diet all foods containing haemoglobin and chlorophyll for at least three days before the test, affirming that without such a precaution the tests are valueless. A notable exception to this is Maclean,[4] who states categorically that such precautions are not at all necessary. No investigations of the question are, however, quoted by these authorities. Abrahams[11] found that it was necessary to take 1 c.cm. of blood by the mouth before any reaction was produced in the stools, on a diet free from haemoglobin and chlorophyll. This observation was the result of personal experiments carried out by himself and his assistant; it is quoted by Bennett,[5] who nevertheless also holds the view that the diet must be rigidly controlled.

On the Continent, and especially in Germany, the problem has been studied on a more experimental basis. Koopman[6] and Gregersen,[7] after performing a great many tests, expressed the opinion that the pyramidon and benzidine tests as generally used are too delicate, giving a positive result where no pathological amount of blood is present, and Gregersen recommends a 0.5 per cent. solution of benzidine as likely to give more reliable results. He states that less than 1 in 3,000 to 1 in 20,000 of blood in the stools cannot be considered pathological. Gregersen and Adler,[8] working independently, found that none of the non-meat foods, tested *in vitro*, gave a positive reaction, and Gregersen maintains that contamination in preparation alone is responsible for a reaction with foods containing chlorophyll. Boas,[9] though he recommends the Gregersen test, nevertheless excludes meat, fish, and certain vegetables from the diet—for example, French fried potatoes. In America Aaron[10] has used the Gregersen test, and heartily recommends it. All these writers, however, declare that, in order to obtain a reliable result, meat, and vegetables cooked in such a way as to include the possibility of contamination, must be excluded from the patient's diet for several days before a test. Other alleged fallacies that have been mentioned are bleeding from the gums, the use of hard tooth-brushes, sucking of the teeth, and iron medicines.

The object of the investigation here reported was to inquire into these "fallacies," and to bring the examination of the stools for occult blood within the scope of the busiest general practice equally with the examination of the urine for albumin and sugar. The large number of patients with carcinoma of the stomach first seen by a surgeon or physician at a general hospital in an inoperable condition, and the large number of patients suffering from gastric or duodenal ulcer who are first seen after the calamity of perforation, emphasize the importance of this. It was therefore decided to use only readily applicable chemical tests, and to select from among the many different chemical tests and methods two of the most reliable, in order the more readily to estimate the value of the results obtained. Spectroscopic tests are not well adapted for use in general practice; while, as almost every author uses a different chemical test or method, it was felt that any attempt to include them all and compare results would tend to confuse the issue.

The Tests Used.

Pyramidon.—A "button" of faeces is taken by means of a clean glass rod from the centre of the stool; it is important to take it from the centre, as no risk of contamination in the lower bowel—as from haemorrhoids—must be run. An emulsion is made in 5 c.cm. of distilled water, a few drops of glacial acetic acid added, and the whole boiled. An inch of the cooled emulsion is then taken, and 16 drops of glacial acetic acid added; 1 c.cm. of a 5 per cent. alcoholic solution of pyramidon is poured gently down the side of the tube so as to form a clear layer on the top, and the same amount of hydrogen peroxide added in the same way. A deep blue colour should develop within fifteen seconds if the reaction is positive, and this is the standard used here in judging the results.

Benzidine [illegible] up containing 0.2 gram of barium [illegible] benzidine; if put up in wax pap [illegible] Just before the test one powder is dissolved in 5 c.cm. of a freshly prepared solution (50 per cent.) of acetic acid. A portion of the faeces is taken as before and smeared on to a clean glass slide, and a few drops of the solution run on to the smear. A blue or blue-green colour develops within a minute if the test is positive, and the reaction is graded according to the depth of the colour and the time it takes to develop. Gregersen recognizes three grades: 1+, a pale blue or green colour within sixty seconds; 2+, a definite pale blue in twelve to fifteen seconds; 3+, deep blue within three seconds. These grades have been adhered to, except that a blue-green colour developing after thirty seconds has been labelled "Faint 1+" and regarded with suspicion.

PRINCIPLE OF THE TESTS.

The principle of these tests rests upon the fact that a colourless substance such as benzidine or pyramidon is oxidized by hydrogen peroxide, with the production of a blue colour, *only* in the presence of a carrier, such as haematin.

First Series.

As a preliminary an investigation of some of the common foods, cooked in the usual way, was carried out. This was not intended as a complete study, but for purposes of reference was thought to be sufficient. The foods used were meat, chicken, fish, egg, potato, cabbage, lettuce, and beef dripping. These were tested after ordinary methods of cooking (boiling, frying, and stewing), and also, in order to test the effect of "contamination in cooking," roasting and pickling in certain cases.

Only two foods cooked in the ordinary way gave any sort of positive result—namely, meat and chicken; and chicken gave no colour with the Gregersen test until after thirty seconds, and so may be disregarded as a source of confusion in the examination of the stools for occult blood. "Contamination in cooking" gave two interesting results, though otherwise negative. These were with meat and pickled herring. Roast beef gave an immediate reaction (3+) with Gregersen's test, as compared with a "2+" reaction with stewed mince, while pickled herring gave an immediate positive, as against completely negative results by other methods of cooking. Fried eggs, and the French fried potatoes, regarded by Boas as a potent source of error, were negative. Both roast meat and pickled herring are "basted" in the oven, the herring afterwards being pickled in vinegar; the basting would appear to have some bearing on the result. In this connexion it is interesting to note that dripping, whether beef or mutton, raw or fried, was negative to both tests. Vinegar is negative, but it is possible that the prolonged treatment with acetic acid, in the case of the pickled herring, may have some bearing on the result.

Second Series: Experiment on a Normal Individual.

A personal experiment was carried out in order to investigate the effect of ordinary articles of diet and certain methods of cooking on tests for occult blood in faeces; I considered myself normal in every way for the purpose in view. The experiment was continued for twelve consecutive days, the specimen being taken first thing each morning. The diet on these days was varied to include as many foods and methods of cooking as possible, the foods including bacon, beef, mutton, chicken, sausage, potatoes, and green vegetables. After three days on ordinary diet an entirely fish diet was taken—the fish being boiled, fried, and pickled—for three days. On the seventh day three ounces of raw meat, minced, was added to the ordinary diet, and on the eighth day two ounces of boiled ox-blood was taken. For the remaining days an ordinary diet, varied as much as possible, was taken, including on one day pickled herring again. The foods were roasted, boiled, fried, stewed, and pickled. All the tests were completely negative up to thirty seconds with Gregersen's method, and only one specimen gave a reaction after thirty seconds. This was on the first day's diet,

when a faint green colour appeared at fifty seconds. This was the only specimen which gave any reaction with the pyramidon also, and that a faint one. The diet on this day was fried bacon, roast meat, green vegetables, boiled potatoes, and fried sausages. "Contamination in cooking" might possibly have been a factor, but on subsequent days this risk was at least as great, especially on those days when pickled herring was taken, which, as stated above, gives an immediate deep blue colour with Gregersen's test. Three ounces of raw meat failed to give a positive result with either test, while the cooked ox-blood, which was taken in amount sufficient to give a definite reaction if uncooked (two ounces), also gave no reaction in the stools.

Thus it seems that meat, and especially underdone meat, may cause a green coloration after thirty seconds with Gregersen's test, and a positive result with the pyramidon test. The important conclusion indicated is that a blue or blue-green colour with Gregersen's test, obtained before thirty seconds, is proof positive of the presence of occult blood in the stools, irrespective of the patient's diet.

Third Series: Investigation of Thirty Pathological Cases.

Thirty pathological cases were investigated, all of the "fallacies" before mentioned being thus included; the cases were thought to be fairly representative of those found in the medical wards of a general hospital. All the tests were repeated.

Teeth-sucking and bleeding on brushing the teeth occurred in practically every case, but in spite of this fourteen out of thirty cases gave a persistently negative result (seven of them on full diet). Seven cases gave a faint coloration after thirty seconds (what has been called the "faint 1+" reaction); nine cases gave more definitely positive results. Of the seven patients who gave the "faint 1+" reaction, in five the diet could not be excluded as a possible cause; but in the two remaining—a case of chorea and a case of acute rheumatic fever—the bleeding could fairly be attributed to the alimentary canal. In the case of chorea the result persisted unchanged after all gum-bleeding had ceased and the diet had been strictly controlled, while in the rheumatic patient, although the diet produced a negative result, this appeared to be due to cessation of bleeding, as a subsequent full diet (roast meat, green vegetables, etc.) failed to reproduce the reaction.

Of the nine patients who gave more definite results, only five were taking any solid food whatever, and in four of these diet restriction produced no alteration in the tests. The fifth, a case of acute rheumatism, gave a "2+" reaction (blue in twelve seconds) and a definite pyramidon reaction; in this case it was unfortunately impossible to obtain a second specimen until too long afterwards to be of any value. The patient was, however, on a diet of boiled chicken and boiled fish, and a reference to the first series of tests will show that boiled fish is negative, while boiled chicken gives no result until after thirty seconds. It is inconceivable that such a diet could produce a stool giving a blue colour in twelve seconds. He had no gum-bleeding or carious teeth, contrary to the usual findings. Two out of the remaining four cases are interesting as illustrating Maclean's[4] contention that milk diet tends rather to cause confusion by checking bleeding. These patients—cases of duodenal ulcer with recent melaena, who had large amounts of occult blood in the faeces—gave a negative result to both tests after four days on milk diet.

Gum-bleeding and Haemoptysis.

It is difficult to assess the importance of these symptoms as fallacies, owing to the variations to which they are liable, but the amount of bleeding should be taken into consideration. Slight bleeding may be discounted, as instanced by one case of Henoch's purpura, where persistently negative results were obtained in the presence of definite gum-bleeding; there were no other haemorrhages in this case, which was in a quiescent phase. In a case of chorea with slight definite gum-bleeding, the faintly positive result was still obtainable seven days after the bleeding had ceased; showing that the bleeding, though obvious clinically, was negligible in the stools. Two cases, one of bronchiectasis with haemoptysis, and the other of ankylostomiasis (*Ancylostoma duodenale*) with gum-bleeding, gave results which it is impossible to exclude as fallacious. In these cases the bleeding was severe.

Iron Medicines.

Two patients with pernicious anaemia, who had been taking iron continuously for over three months, gave persistently negative results. Another case of pernicious anaemia was taking bone marrow, and this seems to illustrate a definite fallacy. The patient died soon afterwards, and at the necropsy no signs whatever of haemorrhage or erosion of the alimentary tract were discovered, although a "3+" reaction was obtained in the stools three days before death.

The Tests Compared.

On comparing the results obtained with each test one cannot fail to be struck with the greater delicacy of the pyramidon reaction. The pyramidon invariably gave a more definite reaction in cases where it was possible to differentiate. The more delicate a test, the less reliable is it for the purposes of clinical diagnosis, as positive results may be obtained where blood is not present in pathological amount. Thus it will be seen that the Gregersen test is the better adapted for clinical purposes.

Summary.

Certain of the common articles of food, cooked in various ways, have been tested; thirty pathological cases on various diets, and exhibiting all the alleged fallacies among them, have been investigated, and a personal experiment has been carried out. The results have been discussed, and the following conclusions have been arrived at:

1. The Gregersen reaction is more reliable than the pyramidon, but blue or blue-green colour must appear within thirty seconds to make the result conclusive.
2. "Basting" seems to have an effect in producing a reaction with foods, but frying has no such effect.
3. Bleeding due to hard tooth-brushes or teeth-sucking, and slight degrees of gum-bleeding and haemoptysis, may be disregarded, although severer degrees of bleeding may cause confusion.
4. Iron medicines produce no "occult blood" reaction in faeces, but the ingestion of red bone marrow is incompatible with a reliable test.
5. A blue or blue-green colour with Gregersen's test, appearing within thirty seconds, is proof positive of the presence of occult blood in the stools irrespective of the patient's diet.
6. Meat in the diet may occasionally cause a faint colour with Gregersen's test after thirty seconds.
7. Occult blood may occasionally be present in the stools of patients suffering from acute rheumatic fever and chorea.
8. A milk diet is liable to cause confusion by checking bleeding.

I wish to thank Dr. J. C. Spence, in whose laboratory the work was carried out, for his encouraging advice and criticism.

BACTERIAL TOXAEMIA AND CARDIAC PAIN.*

BY

WILLIAM GORDON, M.A., M.D.CANTAB., F.R.C.P.LOND.,

SENIOR PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL; PHYSICIAN TO THE WEST OF ENGLAND EYE INFIRMARY.

THE study of cardiac pain suffers, it seems to me, from its existing nomenclature. Eighteenth century names may still serve in the daily routine of practice; but for the purposes of investigation I think we shall do well to make a fresh start, by calling cardiac pain of all sorts simply "cardiac pain," just as we call all abdominal pain simply "abdominal pain," and recording plainly and

* A paper read at an intermediate meeting of the South-Western Branch at Torquay on March 31st, 1927.

precisely the natural history of each case. I shall therefore avoid, as far as possible, the older terminology.

During the past two years I have been surprised by the unusual frequency with which I have met with cases of cardiac pain; and another doctor has, I learn, had a similar experience. Most of these cases have been apparently ordinary enough types of the complaint, in which no unusual cause could reasonably be assigned; but some have been suggestive of an infective factor in their causation, in a way to which I was unaccustomed.

The short series of cases which I am going to place before you consists, first, of five which seem to be due to some epidemic infection, such as we are in the loose habit of calling "*influenza*"; and secondly, of three cases apparently partly due to bacterial toxaemia of other sorts.

First, then, the possibly epidemic cases.

CASE I.

A professional man, aged 62, had, in the beginning of July, 1925, a severe attack of so-called "gastric influenza," with a good deal of pain. *X*-ray examination excluded ulcer. About mid-July the painful "heartburn" began, as the patient expressed it, to extend to the chest after walking. A walk of even a hundred yards caused retrosternal pain, just like "heartburn," which reached from the epigastrium to the neck, ran out under both clavicles and down both arms to the elbow and under both scapulae. There was no dyspnoea, no faintness, no "sense of impending death"; only the feeling that he must stop. In a few minutes the pain passed off and he could again walk for a short distance, when it returned. He was able to carry on his work, since it involved no great physical effort. About mid-August his heart began to intermit frequently, especially in the later afternoon, when it often dropped one beat in three. Still he went on working, and, with strychnine and an antiseptic stomach mixture, matters slowly improved and the intermissions ceased about October. In a few months the gastric symptoms also ceased, but the disability in walking continued. The diagnosis made was toxic myocarditis. An *x*-ray examination showed the heart to be of normal size, the systolic pulse tension was only 140; an electro-cardiogram indicated only some left-sided preponderance. The urine was normal. The patient had never had syphilis. At 23 there had been a slight attack of subacute rheumatism, which had left no discoverable damage. Before the gastric attack he had been a good walker and there had never been any cardiac disease.

By March, 1926, there had been further improvement, and on going to a bracing seaside place he found that he could walk slowly on the level for about three miles. In June a month's holiday produced additional benefit, and since then progress has been continuous though slow. Throughout this case there has never been any very severe pain.

CASE II.

Another professional man, aged 57, while out walking in May, 1925, was suddenly taken with pain in the chest, just behind the upper part of the sternum, not severe. Two days later, when making an extra effort raising a heavy bar, it came on severely. Next morning he had to go to bed; it began to come on in spasms three or four times a day. It then spread all over the front of the chest and over the abdomen, so that the medical man attending him suspected gall stones. He stayed in bed five or six days, but when he got up again the pain was just the same. On June 20th his own doctor came back and his temperature was found to be up to 100° and even 101.4° at night. This ceased after eight days. The pain was severe enough to require morphine. He was sick once, but that was after morphine. This attack of fever was the only definite proof of an infective process found, but the temperature had not been taken before.

When well enough to go out he found that he could not walk even on the level for 200 yards without being pulled up by pain and having difficulty in returning. *X* rays showed nothing. For weeks there was very little improvement. In September he went to Hastings and found there that he could walk slowly one mile on the level. On returning home he lost ground again. In the summer of 1926 he went to Margate and got much better. He was then able to walk further and to go up hills slowly. On his return home this improvement persisted, and about Christmas last he was very much better. Now he is nearly well, but finds he must not hurry.

Although here we have no such preceding gastric attack, I have put this case next the first one on account of the close resemblance of the heart condition and of the course of the illness. Time only, he says, and change of air have seemed to affect his symptoms.

CASE III.

A nurse, aged 25, was under my care from October, 1925, to February, 1926, with cardiac pain following an attack of coryza and bronchitis called "influenza." She had aortic regurgitation dating from 1911. The pain was retrosternal and to the left of the sternum. At first the temperature was normal, but then became irregularly febrile, rising to 99° to 100° each evening. On November 23rd it touched 103° with a rigor, falling, however, to its usual level next day. Blood cultures were negative. On December 2nd she was given cyllin ɱ 1 in capsule three times a day, which soon brought down the fever. On January 4th it again rose, when the cyllin was increased to ɱ 2 every six hours. The temperature then became normal and stayed so. At the same time the cardiac pain, which had been considerable, sometimes needing morphine, and resisting nitrites, iodides, and salicylates, disappeared.

She went to Torquay and returned well. I saw her again on November 24th, 1926, for a return of the pain, slight but continuous across the sternum at the level of the third rib, and radiating up behind the left ear, behind to the scapula, and down the left arm. Ordinary treatment sufficed, and now she is well and at work.

CASE IV.

A stout lady, aged 64, liable to "rheumatism," came to me last September complaining of pain in her arms, shoulders, and breasts, coming on during walking, especially uphill, almost unbearable, usually in the afternoon. Between the attacks of pain she felt very well. Eight weeks before she had had an attack of "cholecystitis," diagnosed by a very capable man, which cleared up. I found a tender mid-sternum, a much dilated heart, a blood pressure of 240/140, mitral systolic and aortic systolic murmurs; also a septic tooth, which I condemned.

On December 3rd I saw her again, when she had lost her pain. The tooth had come out—"an awful tooth," she said.

I wish here to draw attention both to the preceding abdominal illness and to this tooth.

CASE V.

I only heard of this case, and in no detail, so must not vouch for exactness. I include it to show the experience of another and the quicker recovery of a younger man. It occurred in the summer of 1925. A healthy youngish man had an attack of "gastric influenza," and after it found himself unable to walk a moderate distance without being stopped by pain in his heart. In this case, I am informed, the pain disappeared in a short time—in ten days, I think—leaving him quite able to play his usual golf.

These five cases seemed to me to form part of a sort of epidemic of cardiac pain as well as of other forms of cardiac disturbance, in some cases at least, following some infective condition, generally regarded as "influenza."

The following were associated with other sorts of bacterial toxaemic conditions.

CASE VI.

About Christmas, 1924, a busy professional man, aged 67, began to have attacks of cardiac pain, pretty severe for half an hour in the evening, with a blood pressure of over 200, and, after three of these attacks, was seized suddenly after dinner with an intense pain over the whole front of the chest, especially between the left nipple and clavicle, running down the left arm. Nitrites had no effect, and recourse had to be made to morphine and finally to chloroform. For several days chloroform was used for recurrences. A very irregular pulse was left for six weeks, and when he was allowed out, walking brought on a slighter cardiac pain. He noticed that one of his teeth was loose, and, although it was not causing toothache, he had it removed. It smelt abominably. Within two weeks of its removal the pulse became regular, and he has since had no recurrence of the violent pain. However, walking any distance, especially uphill, still brings on slight pain a little above the left nipple and round his left wrist. This disability is steadily diminishing and is now indeed negligible.

CASE VII.

A boy, who was brought to me with dilated right heart following a bad abscess under a tooth six weeks previously, told me that an uncle had come home from abroad suffering from what was diagnosed as "angina pectoris"—"terrible cramp in his heart," he explained—which he had suffered from for two years, that his teeth had been found septic and put to rights, with the result that the "angina" had ceased and he had been able to resume his duties.

CASE VIII.

A lady, a stout, pale woman of 67, with a satiny skin and slightly dilated heart, who had been short of breath for thirteen years, was lately seized with severe pain behind the upper sternum and "through to the back." Treatment of an ordinary kind remedied matters. But it was found that she had a painful anal fissure and above it a vast accumulation of faeces.

I am well aware that these few cases provide only a very slight picture of what I submit they certainly suggest. But I hope that you will feel that I have not wasted your time in using them, insufficient as they are (1) to draw attention to a factor in the causation of a very serious condition, whose fuller recognition may prove to be of practical use, and (2) to record what I think has been something approaching an epidemic of cardiac pain due to some epidemic toxaemia.

It may be of interest to recall that Arnold of Rugby, whose death from "angina pectoris" is historical, is said by his biographer, Dean Stanley (vol. ii, pp. 270 and 277), to have "been confined to his room for a few days by an attack of feverish illness," which apparently caused "depression" for over a week, three weeks before his fatal attack.

THE TREATMENT OF CARCINOMA BY LEAD COLLOIDS.

BY

DUNCAN C. L. FITZWILLIAMS, M.D., F.R.C.S.,

SURGEON AND LECTURER ON SURGERY, ST. MARY'S HOSPITAL, PADDINGTON.

As it has been my experience, and that of many who have been using the later preparations of colloidal lead prepared by the British Colloids Company and others, that considerable reaction has been met with after injection, Mr. Patterson has asked me to state the results obtained with the colloidal iodine preparation[1] with which he has been supplying me for nearly two years. Mr. Patterson has had considerable experience in the preparation of lead colloids with the Liverpool centre.

This preparation has been used by me in some sixty odd cases of malignant disease in St. Mary's Hospital, Mount Vernon Hospital, and also in private. Beyond the first batch of about half a dozen cases none have had any reaction whatsoever, and the reaction in the first cases, we thought, was probably due to some contamination of the preparation, as it had been opened and examined previous to use. Reaction never again followed the use of the colloidal iodine.

The preparation contains 0.2 per cent. of lead in the form of lead iodide. It is intended for intravenous injection, and so it is made isotonic by means of glucose, for sodium chloride would be unsuitable in the presence of lead. It contains, further, a trace of thyroid extract; the exact amount cannot be given, for the dried extract contains a varying proportion of inert matter, but it may be definitely stated to be less than 0.02 per cent. A trace of cresol is added, to act as a preservative, since glucose is present. The addition of the trace of cresol is not regarded as making the preparation sterile; it is sterile, and the cresol is added purely as a precautionary measure.

The usual course is four doses, given at four to five days' interval, with the precautionary tests for the urine, blood, and the liver efficiency, which are insisted upon by the Liverpool centre. I have given three courses at intervals to some patients, and in one I gave ten doses at weekly intervals.

This method of treatment cannot, and does not, attempt to replace operation. It is important that the growth should be removed as widely as possible, and the injections then given in the hope that they will attack any small foci which may have started in the internal organs.

The method may be used with advantage, and the results are best seen, in inoperable cases. There is every hope that, though a cure may not be brought about, the rapidity of the growth may be lessened, and at the same time it gives the patient the feeling that something is being attempted. Too many cases are brought which are past all hopes of being benefited in the smallest degree. In early cases, where operations and other procedures, such as radium and *x* rays, are used, the results can hardly be attributed to one agent or to one procedure, and therefore definite scientific data are very difficult to obtain.

It is too early, of course, to attempt to publish results obtained from the injection of lead, but there is no doubt that lead colloids give satisfactory results sufficiently frequently to justify hope that the growth may be retarded or may even disappear. At the same time, the limitations of this form of treatment must be realized. It is a most unsuitable form of treatment to give when the walls of a hollow viscus have been extensively invaded by the growth, because destruction of the growth means destruction of the wall of the viscus, and rapid death must follow. In certain cases, as in oesophageal strictures where a gastrostomy has been performed for cicatricial contraction of the oesophagus, this contraction has been greatly increased and the growth of a tumour brought to a standstill, so that the word "cure" may almost be used, but cure will not mean the restoration of the natural passages.

In passing, I might say that in one of my oesophageal cases the large, hard mass of secondary glands in the neck disappeared. A second case was lost through destruction of the growth. Two large secondary masses of breast carcinoma, which had recurred on the chest wall, completely broke down during the course of injections; unfortunately, one of the masses had penetrated the chest wall, and the breaking down set up septic pneumonia in the lung to which it was adherent, and the patient died. In yet another case of breast carcinoma, where the breast had been removed and a course of treatment given, internal secondary growths broke down, and the patient died through haemorrhage, because one of the growths had invaded the wall of the splenic artery. It may some day be possible to obviate these accidents.

Growths of the solid variety or in the solid viscera, or in situations which are not vital, may be dealt with fearlessly. Patients suffering from kidney disease with albumin in the urine, or showing the extremes of anaemia, are hardly subjects for such treatment.

In conclusion, I have to thank Mr. Patterson for kindly letting me make use of his preparation in the above cases. I gladly accede to his wish that I should state the harmlessness and absence of reaction of the preparation. I have used material from one single batch for more than a year, which proves that the preparation may be considered perfectly stable.

[1] The commercial manufacture of the preparation has been undertaken, under the personal supervision of Mr. Patterson, by the British Drug Houses, Ltd., Graham Street, London, N.1.

THE COMPARATIVE VALUE OF THE "AMMONIA COEFFICIENT" AND THE RATIO BETWEEN FREE AND AMMONIA-COMBINED ACID IN URINE.

BY

O. C. M. DAVIS, M.D., D.Sc.,

LECTURER IN CHEMISTRY IN THE UNIVERSITY OF BRISTOL; PHYSICIAN TO THE ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN;

AND

F. W. RIXON, PH.D., M.Sc.,

LECTURER IN CHEMISTRY IN THE UNIVERSITY OF BRISTOL.

THE object of this communication is to consider the comparative value of two quantities which are used in the examination of urine, both of which give a valuable indication of physiological activities. The comparison was instituted with a view to determining which of these two values has the better practical diagnostic possibilities. Both quantities are ratios, and the mechanism involved in the case of one of these was outlined by us at the provincial meeting of the Children's Section of the Royal Society of Medicine held in Bristol in June, 1923,[1] and dealt with more fully subsequently.[2]

The first of these ratios is obtained by titrating 25 c.cm. of urine with decinormal sodium hydroxide solution, using as indicator phenolphthalein; this gives the free acid value; then to the same solution neutral formaldehyde solution is added (Folin's method), when a further titration with alkali gives the ammonia-combined acid, or ammonia.

The ratio, which we will designate R_A, is obtained by dividing the second titration by the first, and represents the ratio of ammonia to free acid present in the urine. The second ratio involves the same titrations, but in addition the nitrogen is determined by the usual hypobromite method; a ratio is obtained by comparing the nitrogen existing as ammonia with the total nitrogen from the hypobromite determination. This ratio we will call R_U. The two ratios are therefore:

$$R_A = \frac{\text{Ammonia}}{\text{Acid.}}$$

$$R_U = \frac{\text{Nitrogen as ammonia}}{\text{Total nitrogen (hypobromite).}}$$

As a practical point it will be seen that R_U requires a third determination which is by no means as accurate or simple as the ordinary titrations needed for R_A. (R_U closely corresponds with what is generally termed the "ammonia coefficient.")

The employment of ratios is of considerable importance, since the wide variations in concentrations of urine would stultify results considered singly because the quantity of

urine secreted over some period must be measured; by employing ratios valuable indications are given from examination of a single sample, especially if the specimen is selected by the method we have indicated.[2]

Considerable variation in concentration of urine may even affect these ratios, and for this reason results obtained from very dilute urines are not considered. This variation is a matter with which we hope to deal in a further communication.

The question might very reasonably be asked, Are these ratios merely empirical, or is there any physiological reason for their use? That is to say, have they a theoretical as well as a practical basis? For R_A there is such a basis of theory, as it indicates the effort that is being made to maintain the constant reaction of the blood, giving information of value in assessing its state and more particularly the amount of buffer salts present. The ammonia secreted may be compensatory, or in certain cases may arise from incomplete metabolism; with its source we are not immediately concerned.

With the ratio R_U there appears to be no blood mechanism which relates ammonia to urea; the urea in blood may normally vary within wide limits, and R_U may or may not be a purely fortuitous ratio depending upon the source of the excess of ammonia. The value of the ratio may really be in the numerator which happens arithmetically to be little disturbed by usual variations in the denominator.

It is interesting to note that Palmer and Henderson make use of an inverted form of R_A, but attach no special significance to it, though they find it a convenience in their pathological studies.[3]

Opinions differ as to the normal value for R_U; Wells[4] gives the proportion of nitrogen in urine in the form of ammonia as from 2 to 5 per cent., which in diabetic acidosis may rise to 10 to 25 per cent. Todd[5] states that normally about thirty times more nitrogen is excreted as urea than ammonia, and when the ratio of urea to the ammonia nitrogen is as 10 to 1 or more, we are justified in saying that acidosis is present, but figures between 10 to 1 and 20 to 1 point to defect of the liver. Burgess[6] gives an average value in a series of normal children of 7.04. The figures we have obtained are more in agreement with those of Burgess. There would seem to be something unsatisfactory when a ratio which is given normally in the neighbourhood of 4 (Wells and Todd) has to increase to as much as 10 before it has indicative value.

The normal value of R_A ranges up to 1.5; a value exceeding this for an early morning specimen, having a first or acid titration greater than 5 c.cm., indicates some derangement. This is in agreement with the values given by Palmer and Henderson,[3] where the quantities are comparable.

To summarize briefly: Of the two ratios R_A is more accurately and readily determined, and it is definitely connected with a well established mechanism. R_U, including as it does the same numerator as R_A, must in a measure give similar indications, but is affected by a denominator which does not appear to have any definite connexion with the numerator such as is found in R_A.

Experimental.

Some fifty samples of early morning urine, presumably normal, gave the following values:

	Average.	Minimum.	Maximum.
R_A	1.02	0.6	1.5
R_U	6.6	3.4	9.0

so that in normal urines the two ratios run along fairly parallel lines. More interesting are the results of a similar comparison in cases not normal.

Case 1.—A case of cyclic vomiting in a little girl which we were fortunately able to observe also during normal health.

In normal health:

R_A ...	1.03	1.0	1.05	1.50	1.07	1.23	1.13	0.87	1.11
R_U ...	8.2	7.1	7.8	6.1	5.9	6.7	6.6	6.5	6.8

During attack and recovery:

R_A ...	4.47	4.09	1.56	0.84	1.35	1.34
R_U ...	8.9	10.4	8.0	6.4	8.7	9·3

It will be seen that whereas R_A indicates clearly a considerable derangement, R_U gives no very definite information.

Case 2.—A case of simple acetonuric vomiting. We were able to observe this patient also during normal health.

In normal health:

R_A ...	1.23	0·87	1·01	1.22	1.20	0.96
R_U ...	7.3	6.7	7.0	4.9	3.8	7.3

During attack and recovery:

R_A ...	2.10	1.75	1.88	2.0	1.21	1.40
R_U ...	9.9	9.8	4.6	5.9	7.6	8.1

Case 3.—A case similar to 2; the ratios were recorded during attack and recovery:

R_A ...	2.49	4.25	2.57	1.55
R_U ...	10.7	11.3	5.35	5.35

Case 4.—This was a case of diabetes, the patient being an adult male.

R_A ...	2.07	1.82	2.60	3.60
R_U ...	14.8	5.9	15.4	13.0

Here the ratio R_A is uniformly consistent with a marked derangement of function, but R_U fails to indicate this in one case.

Case 5.—A case of catarrhal jaundice in small girl.

R_A ...	2.13	3.36	3.25
R_U ...	15.2	17.3	14.6

Case 6.—A case of catarrhal jaundice in a girl aged 10 years.

R_A ...	1.62	2.0	2.0
R_U ...	4.4	7.1	7.5

A few cases in health and when unwell where a series of specimens of urine were not available:

	Ill.	Well.	Ill.	Well.	Ill.
R_A ...	3.54	1.29	2.22	1.36	3.62
R_U ...	14.5	6.6	8.2	4.7	15.8

It will be seen from these tables that on some occasions both ratios give similar indications, but in certain instances when R_U fails to denote any derangement R_A shows distinct abnormality—that is, R_A appears to give more generally reliable information than does R_U. As the value of these ratios is affected by taking alkalis or acids, the above results were drawn from cases where the administration of drugs containing these substances was not immediately essential in the treatment.

There still remains a considerable volume of work to be carried out upon this and similar ratios, and it would seem highly probable that by careful comparison of values obtained from various ratios it might be possible, not only to discover a derangement in physiological mechanism, but also in a measure to locate it, and we are carrying out a further investigation on the subject.

Conclusion.

Two ratios have been compared, and of the two the first—namely, the ratio of ammonia to acid present in a specimen of urine—seems to give generally better information, and has the advantage of being much more readily and quickly determined.

THE PERINEAL AND PELVIC FLOOR MUSCLES IN THE SECOND STAGE OF LABOUR.

BY

R. K. HOWAT, F.R.C.S.,

HONORARY SURGEON, NORTH RIDING INFIRMARY, MIDDLESBROUGH.

THE care or management of the perineum consists in the use of means for the prevention and limitation of perineal rupture in labour. It applies to the later period of the second stage, the period of perineal distension. The teaching, express and implied, that during the pains of this period the perineal muscles are in a state of contraction seems opposed to some obvious phenomena of labour. This prompted a reference to a number of books on midwifery in order to discover if the teaching were common, and in hopes of learning the evidence on which it is based.

Sixteen textbooks and manuals of midwifery, published from 1899 to 1923, were consulted. Twelve do not mention

the matter, four do. In two of the four the same author is concerned. The terms used are such as these:

Between the pains the pelvic floor is relaxed, not rigidly contracted; try to deliver between pains, the perineal muscles being then relaxed instead of tightly contracted; spasmodic rigidity of the muscles of the pelvic floor obstructs delivery; during a pain there is contraction of muscles of the pelvic floor and outlet; this makes the perineum more rigid and therefore more liable to tear.

All this may be summarized to mean that whilst the perineum is becoming more and more stretched (that is, during the pains) its muscles and those of the pelvic floor are in a state of spasmodic, tight, or rigid contraction, and that this obstructs delivery and favours laceration. This seems to signify that the mechanism of a physiological function normally so acts as to obstruct its completion and favour its injurious accomplishment—a view hard to accept without very satisfying evidence in its favour.

A little consideration of the conditions of the second stage compared with the effects of contraction of perineal and pelvic floor muscles will serve to indicate the difficulty of accepting this teaching. The coccygei and levatores ani in contracting flex the coccyx forwards and upwards upon the sacrum and raise the ano-coccygeal raphe; during the pains the advancing head forces the coccyx downwards and backwards in extension upon the sacrum and depresses the ano-coccygeal area. The pubo-coccygeal fibres of the levatores ani in contraction oppose bilateral distension of the anal canal; during the pains the advancing head spreads the anal canal bilaterally and forces the adjacent edges of the levatores ani far apart. The sphincter ani in contraction closes the anus; it is precisely during pains that the anus is stretched more and more widely open. The compressor vaginae in contraction constricts the vaginal orifice; this orifice is stretched more and more widely open by the head advancing during the pains.

Thus it appears that during the pains of the perineal "management" stage the muscles of the pelvic floor and perineum are stretched, as indeed are all the perineal tissues. They are not contracted, and therefore it is not true that their contraction opposes delivery and favours laceration. Considering the condition of the perineum during a pain just before delivery—bulging, stretched in all directions, tense as a drumhead—one wonders what is the evidence and how precisely it was obtained for the teaching in question. But on these points the books are silent.

A CASE OF HYDATID PNEUMOTHORAX.

BY

R. G. ANDERSON, M.B., B.S.,

HOUSE-PHYSICIAN, RADCLIFFE INFIRMARY, OXFORD.

THE rupture of a hydatid cyst of the lung into the pleural cavity is a rare cause of spontaneous pneumothorax, and it is therefore considered that the case detailed below is worthy of record.

This condition was first described by Fouquier in 1828, two years after the death of Laennec. He states that at the autopsy on a case of spontaneous pneumothorax "the right chest was half filled with a yellow turbid fluid in which floated a sac the size of a large nut, rather soft, of milk-white colour, and semi-translucent, which one could not fail to recognize as a ruptured hydatid cyst." In 1925 Professor F. Dévé of Rouen[1] collected thirty-one authentic cases. Since then one other case has been reported by Bacaloglu and Tanasesco.[2] The condition occurs most frequently in young adults, and in males twice as often as in females. The rupture is usually precipitated by a sudden effort.

The perforation in the pleura is commonly situated on the inferior lobe of the lung and more often on the right side than the left, thus differing in this latter respect from pneumothorax secondary to tuberculous disease. It may be round or linear, admitting the tip of the finger or measuring several centimetres in length. The perforation leads into a cavity in the lung which is not usually larger than an orange. The cyst itself is commonly found free in the pleural cavity and in most cases is ruptured, but in the case described by Mercier in 1838 it was intact and filled with a clear yellow fluid. It is sometimes accompanied by daughter cysts, and, rarely, there is a secondary growth of echinococcus on the pleura, caused by the dissemination of parasites at the moment of rupture of a fertile cyst.

By studying sections of the lung of a rabbit in which the condition had been artificially produced Dévé came to the following conclusions as to the course of events which take place. *There is not a sudden rupture of the cyst into a bronchus, but a gradual invasion of the bronchus by the cyst wall, followed by necrosis of the wall of the bronchus at one point. A pneumocyst is thus produced.* The necrotic plug acts as a valve, the tension in the cyst rises and its wall becomes stretched. Owing to the fact that the part of the cyst wall which is adjacent to the pleura lacks support and that its blood supply is diminished, a slight increase of intrabronchial pressure is sufficient to cause it to rupture.

The hydropneumothorax thus produced may remain sterile for several months. Sooner or later, however, the entrance of organisms from the bronchus, combined with the irritation produced by the presence of the hydatid fluid and the cyst wall in the pleural cavity, leads to suppuration and the formation of a pyopneumothorax.

Case Report.

J. P., a groom, aged 36, had been in South Africa in 1913, and had served in France during the late war. He stated that he had always been fond of dogs and that he kept one in the house. He had suffered from cough since being gassed. There had been no haemoptysis or loss of weight.

On December 17th, 1926, at 10.30 a.m., his cough became much worse, and during the next hour and a half he expectorated about two pints of frothy sputum. He felt better during the afternoon, but at 5 p.m., while walking upstairs, he developed rapidly increasing dyspnoea and severe pain all over the chest, not localized to either side. That evening his temperature rose to 102°. On the following day Dr. MacCormack of Steeple Claydon found signs of pneumothorax on the left side. The temperature remained high until December 21st, and then began to settle down. On December 23rd the sputum was purulent. It was examined, and no tubercle bacilli were found. There was never any haemoptysis. On December 28th and January 2nd air was aspirated from the left pleural cavity, giving relief to the dyspnoea. There was no urticaria. There was no family history of tuberculosis.

He was admitted to the Radcliffe Infirmary on January 16th. He was a thin man with flushed face, orthopnoeic, and obviously ill; temperature 100°, pulse 100, respirations 28. The tongue was dry and furred. Cardiac pulsation was visible below the right nipple in the fifth intercostal space. The area of cardiac dullness was entirely to the right of the sternum. The heart sounds were normal. The left side of the chest was larger than the right; movement of the chest was impaired and vocal fremitus absent on the left side. The percussion note was hyper-resonant on the left side down to the seventh rib, and dull below this level. Weak vesicular breathing was present above the seventh rib and absent air entry below. The bell sound was clearly audible on the left side between the fourth and seventh ribs. The liver and spleen were not palpable. The sputum contained pneumococci.

On January 18th the left pleural cavity was aspirated in the ninth intercostal space. About two pints of creamy pus with air were removed. At operation, the same evening, under gas, oxygen, and ether anaesthesia, one inch of the ninth rib in the left scapular line was resected. When the pleural cavity was opened air at first bubbled out, and was followed by about two pints of pus. There was a large cavity the walls of which could not be reached with the finger. No adhesions were felt. A few flakes of fibrin were removed and a tube was inserted.

The pus was found to contain pneumococci, but was sterile. The temperature continued to swing, rising to 100° every evening until January 24th, when a ruptured cyst was discharged through the wound. The temperature immediately fell and remained normal.

The pathological report on the cyst was to the effect that it measured in its collapsed state four inches in diameter, and consisted of a yellowish substance. On the inner aspect were a few small excrescences, but neither in these nor in the scrapings from other parts were any hooklets found. Microscopically the cyst consisted of a laminated, translucent, non-cellular structure. It was undoubtedly a hydatid cyst.

The chest was x-rayed on February 9th, and no evidence of other cysts in the lungs was found. There was no eosinophilia. The patient made an uninterrupted recovery.

According to Dévé the initial cough in these cases is usually dry. The large quantity of sputum expectorated by the patient in the above case might be due to pulmonary oedema caused by hydatid fluid leaking out when the cyst opened into the bronchus.

The noteworthy points in this case are (1) the opening of the cyst into a bronchus, (2) the production of a pneumothorax six and a half hours later, (3) the valvular nature

of the opening in the pleura which led to an excess of air under pressure in the pleural cavity, and which necessitated special relief on two occasions before admission to hospital.

I am indebted to Dr. A. G. Gibson for assistance and permission to publish this case.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TWO CASES OF COINS IN THE OESOPHAGUS.

THESE cases, which occurred within three weeks of each other, are published in order to show the size of coin that is likely to become impacted in the oesophagus at different ages. Incidentally they also illustrate the fact that a coin which can pass through the upper end of the oesophagus can pass unaided through the rest of the alimentary tract. In both cases the misfortune was caused through the impish mischief of young children, so that a word of caution may be uttered against giving coins to children as playthings.

CASE I.

T. C., a labourer aged 35, while having a meal at mid-day on September 16th, drank a cup of tea rather hurriedly and then felt something in his throat. It was ascertained that his baby had dropped into the cup a penny it had been given to play with; the father tried to vomit, but did not succeed.

On arrival at the hospital *x*-ray examination showed a coin impacted at the level of the sterno-clavicular joint. On endoscopic examination the penny was seen, but the area being somewhat *fouled with blood* from loss of a tooth in a mouth with marked pyorrhoea, it could not be gripped with the forceps, and disappeared. On a second *x*-ray examination it was seen to move freely with respiration at the level of the cardiac orifice of the stomach.

The patient was again *x*-rayed on the following afternoon, and the penny was seen to be in the stomach near the pylorus. He was allowed to go home and told to come up in thirty-six hours. This he did, bringing the *penny in his hand*, and reported that it had been passed in his motions (thirty hours after it had been seen to be lying in the stomach) without any difficulty or any haemorrhage in the stools.

CASE II.

P. K., aged 6½ months, on October 7th, about 5 p.m., swallowed a farthing given to her by *her little* brother. She went red in the face and nearly choked. She was taken to her doctor, who sent her to the hospital. At 11 p.m. *x*-ray examination showed the farthing impacted in the oesophagus at the level of the sterno-clavicular joint. On oesophagoscopy the coin was seen and removed with forceps. The child left the *hospital* three days later in perfect health and with no complications.

I am indebted to my clinical assistant, Mr. Lindenbaum, for his notes on these two cases.

KENNETH A. LEES, F.R.C.S.,
Assistant Surgeon, Throat and Ear Department, St. Mary's Hospital, Paddington.

HAEMATURIA TREATED BY INJECTION OF SERUM.

THE following case is of some practical, apart from a possible theoretical, interest.

A boy, aged 3½, had an attack of haematuria after tonsillotomy about a year ago. I am informed that, apart from one or two interyals of a few days, during which the urine appeared to be free from blood, it had persisted in *varying* degree ever since. The greater part of the year was spent in hospital, where the urinary tract was carefully investigated and an exploratory nephrotomy performed on the left side. Apart from an impression gained that the left kidney was somewhat large, the result of the operation was negative, and the child was discharged from hospital uncured. When I first saw him, in December, 1926, he was still passing bloody urine, was markedly anaemic, and his general condition was very miserable. On examination no abnormality of the kidneys could be detected, and I made the diagnosis of essential haematuria precipitated by septic absorption following tonsillotomy.

I decided to treat the child by injection of horse serum. The first dose of 10 c.cm. was followed by acute urticaria. As the degree of haematuria seemed to have decreased I gave a second injection of 20 c.cm. one week later, both injections being given intramuscularly into the buttocks. After the second injection the haematuria disappeared, and has not since returned. It is, of course, too early to speak of a permanent cure, but as the child had previously been free from haematuria for a few days at a time only, the outlook seems hopeful. The improvement in the general health has been very noticeable, the whining child being now normally vigorous and lively.

Apparently the haematuria was due to absorption of toxins from the cut surfaces of the tonsils. Why these toxins should have attacked the endothelium of the renal vessels is an interesting question. The necessary antitoxins seem to have been produced in the child's body by the injection of the proteins contained in the horse serum. The injection of these proteins produced an attack of urticaria, as is known sometimes to happen, and apparently a by-product of the reaction was the required antitoxin. The sequence of events in this case supports the view that a bodily reaction is necessary for the production of antibodies. On the other hand, the occurrence of haematuria after the operation of tonsillotomy may have been quite fortuitous and in no way due to sepsis, and the cessation of the haematuria may be attributable to coagulants contained in the horse serum. Were it practicable, a bacteriological examination of the remains of the tonsils would be of interest.

London, N.15. L. J. GREEN, M.R.C.S., L.R.C.P.

DEATH FROM HAEMORRHAGE FROM THE AORTA INTO A BRONCHUS.

THE following case is an instance of what must be an unusual cause of death.

An old woman, aged 81, died at the Tooting Bec Mental Hospital on December 20th, 1926; she was admitted on January 27th, 1922. She suffered from senile dementia with marked loss of memory for all recent events, but a remarkable recollection of the past. She could repeat pages of Shakespeare's plays.

She had arterial degeneration to a moderate degree, and experienced several cerebral attacks with transient paralysis. After one of these attacks she lost voluntary control of the right arm, which used to execute all sorts of movements of its own accord, much to the annoyance of the patient, who would lay hold of it with the left hand to keep it in order. These movements ceased when the patient was asleep.

At the time of her death she was seen by a medical officer, who reported that arterial blood had gushed out of her mouth for about ten minutes before she died. At the *post-mortem* examination it was found that a patch of adherent pleura had attached itself to a hard plaque on the aorta. A communication had formed between the aorta and a rather large bronchus, and after filling up the lung the blood had poured out of the mouth till the patient was dead.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

GLOUCESTERSHIRE BRANCH.

The Blood Picture in Various Diseases.

A MEETING of the Gloucestershire Branch was held at the General Hospital, Cheltenham, on March 10th; Dr. J. RUPERT COLLINS presided, and Dr. J. B. DAVEY read a paper entitled "Some interesting blood pictures."

Dr. Davey described the source and antecedents of the cells of the blood. In spite of the multitude of names used by various workers for the same cells, a common ancestor for all the various blood cells was now accepted by the majority. This cell, found both in marrow and in lymphatic tissue, somewhat resembled the large lymphocyte and was named the haemocytoblast. From this cell were formed in the marrow the erythrocytes by loss of nucleus and elaboration of haemoglobins; the myelocytes by development of granules; the large lymphocytes and thence the small lymphocytes, and the megacaryocytes. In lymphatic tissues it formed the large and small lymphocytes. As regards pathological conditions, the most familiar was probably the rapid increase of polymorphonuclears in the circulating blood in septic processes. Many of these cells were of immature type. The marrow was very susceptible to toxic influences, and it was not difficult to conceive that some toxic process was at work in myelocytic leukaemia, where very primitive forms, the myelocytes, were poured into the circulation, their conversion into polymorphonuclears being largely inhibited. In such cases the marrow, at the necropsy, showed clear evidence of great myelocytic activity. In lymphatic leukaemia the process was not so

clear, since although as a rule the lymphatic glands were enlarged this was not invariably the case. Presumably in these cases the haemocytoblasts in the bone marrow were producing the lymphocytes. But it should be noted that some cases of so-called lymphatic leukaemia were not so at all: they were really leukaemias of that very primitive cell, the myeloblast. This cell was strikingly like the lymphocyte, but contained the oxidase granules. In pernicious anaemia there might be some myelocytes, and in an acute leukaemia megaloblasts; it might transpire that these two diseases were not only closely related but were even varieties of one disease. A case of chronic myelocytic leukaemia was quoted in which ragged ulcerated masses somewhat resembling growths were found in the ascending colon. These were masses of myelocytes. Such a picture lent some support to Gulland's theory that leukaemia was a sarcoma of the blood cells. Dr. Davey showed slides under the microscope illustrating the various kinds of cells, and also a case of lymphatic leukaemia in which the clinical course did not extend over more than three months. In another case the illness lasted only fourteen days, and though the cells
was shown that 83 per cent. were
and were therefore myeloblasts.
Goodall's contention that the really acute so-called lymphatic leukaemias were myeloblastic. In a third case the illness began with a lump in the neck, and death followed in eight weeks; the case was one of lymphatic leukaemia. Under one of the microscopes was shown a nucleated red cell undergoing mitotic division, taken from the circulating blood of this patient. In these three fatal cases the white cell count was but moderately raised above normal. Dr. Davey next described the case of a woman, aged 26, with symptoms resembling those of acute leukaemia; the blood picture did not exclude that diagnosis. The case turned out to be one of glandular fever, with a very different prognosis. Dr. Davey described in conclusion two cases of anaemia occurring in pregnancy, each of which had colour indices above one, and megaloblasts were present in the circulating blood. This was regarded as a rare form of anaemia. Transfusion in one case led to a most striking improvement, which was maintained by the administration of arsenic.

The Significance of Optic Neuritis.

Mr. N. H. PIKE discussed the various conditions which are included in the term "optic neuritis," including retrobulbar neuritis, papillitis, papilloedema, or choked disc, neuro-retinitis, and optic pseudo-neuritis. He said that the term "retrobulbar neuritis" was applied to inflammation of the optic nerve behind the eyeball, and that the characteristics of this condition were rapid loss of central vision, some pain on pressing on the globe, a pupil which contracted to light, though the contraction was not maintained, and a marked tendency to recovery. One of the commonest causes was disseminated sclerosis. The accessory nasal sinuses had been blamed for infecting the optic nerve, but Mr. Pike, who had the advantage of being also a rhinologist, had only seen one case in his own experience in which he could trace a causal relation. That case was exceptional in being, not a true retrobulbar neuritis, but a monocular optic neuritis. All the other terms which he had mentioned had in common the fact that they referred to the appearance of the optic disc as seen with the ophthalmoscope. They could be divided into two classes: those due to intra-ocular causes, and those due to intracranial but extra-ocular causes. To the first class belonged the large group of cases of neuro-retinitis, which had as a common factor, speaking broadly, a high blood pressure in the larger arteries. The changes in these cases were oedema, exudate, and haemorrhage; there was no high pressure in the retinal artery. Mr. Pike had demonstrated that in a woman with a brachial systolic pressure of 270 mm. the retinal pressure was actually lower than normal, and so, as an ophthalmologist, he would condemn drastic attempts to bring down the blood pressure. The other class of case—papilloedema or choked disc due to intracranial causes—was in many ways the most interesting. Its development was often described under five stages, but it was a gradual process from start to finish. The amount of swelling of the disc could be measured, and a useful division was to limit the term "choked disc" to a swelling over 2 D. Occasionally a typical choked disc was found as a manifestation of renal disease. Whatever the root cause might be, it had been shown by Horsley to be a direct expression of the mechanical agency of increased intracranial pressure. Intracranial and intra-ocular pressures had been shown to be identical in the normal state. Mr. Pike briefly indicated the extreme complexity of the factors associated with rise in pressure, and pointed out that there was more to be taken into account than the ordinary laws of physics. In Mr. Pike's experience very little reliance could be placed on difference between the discs as a localizing sign. The ipsolaterality of choked disc, on which Sir Victor Horsley laid stress, was not now accepted as of importance. Mr. Pike gave the histories of several cases to emphasize the necessity of decompression for the relief of papilloedema and other pressure signs, and showed numerous lantern slides which illustrated the various physiological and pathological points. In conclusion, while he made a plea for decompression, he drew a sharp distinction between that operation and one designed for the removal of a tumour, which, in his view, was not as a rule successful in a general hospital.

Reports of Societies.

PATH OF INFECTION IN TUBERCULOSIS.

AT a meeting of the North-Western Tuberculosis Society in Manchester on March 31st, Dr. ADAMS, the president, in the chair, Professor S. LYLE CUMMINS read a paper entitled "The bearing of recent laboratory research on clinical conceptions in tuberculosis."

Professor Lyle Cummins said that his experience in the *post-mortem* room had impressed upon him the pleomorphism of tuberculosis in human beings as compared with the uniformity observed in animals. In the laboratory animal there existed what might be called "natural" tuberculosis, the same characteristics being found also in infants and primitive races—namely, generalization of the disease with rapid termination. He contrasted this with the tuberculosis usually seen in human beings—namely, pulmonary disease. Some modifying factor appeared to have been at work, and "modified" tuberculosis tended to be localized in the lungs; intermediately was the large section of surgical tuberculosis which was the aftermath of an unrecognized general tuberculosis, causing metastatic deposits through the blood stream. A later stage was localized disease in the lungs. In "natural" tuberculosis the tuberculin test produced negative or slight reaction; in "modified" tuberculosis there was a marked reaction. "Natural" tuberculosis was characteristic of non-allergic age groups and races; "modified" tuberculosis was characteristic of allergic age groups and races, the modifying factor being the production of allergy. Three questions as regards pulmonary tuberculosis were still unsolved: (1) Was the disease caused by the reawakening of an infection in childhood, or due to the reinfection of an allergic lung? (2) Did the bacilli enter through the alimentary tract or in the inspired air? (3) Why was the disease more commonly apical than otherwise? In regard to (1) much experimental work had been done. Baldwin obtained infected guinea-pigs and tried to reinfect them; he found them very resistant to reinfection, but did succeed with large doses. Krause and Willis introduced an emulsion of bacilli into the skin of guinea-pigs, and found that even one hour after inoculation the cutting out of the piece of skin infected was too late to prevent infection of the animal; if the animal had been previously infected five days was not too late; thus there was great retardation in infected animals. Similarly, they found that in previously uninfected animals the neighbouring glands were reached within twenty-four hours, but in animals previously infected not in twenty-one days. Thus a previous

infection produced retardation and modification of disease. The presence of scars in the lungs of adults was evidence that much early tuberculosis in children did heal. There was a correlation between such physiological influences as childbirth, lactation, strain, and infection pointing to the awakening of an old infection; on the other hand, no infection came from healed scars. There was difficulty in establishing definite sources of infection, but these certainly did occur. Mullins's experiments on rabbits consisted in injecting emulsions of bacilli into the posterior nares of rabbits under an anaesthetic, and he found that either lung could be infected. Soper repeated these experiments with *x*-ray control. The results showed definite parenchymatous lesions in the lung of allergic rabbits long before rabbits previously uninfected developed lesions; in the latter, the reaction, though delayed, was more serious. Calmette held such experiments to be unnatural. To sum up, the evidence was inconclusive, but there were two certainties—namely, that pulmonary tuberculosis was due to a reawakening of previous infection and that strong evidence existed in favour of reinfection. In regard to the second question, Calmette believed in the alimentary route of entry. Guinea-pigs fed on fatty broth containing bacilli showed bacilli in the lacteals in three hours. In early life the mucous membrane was more easily permeable; on the other hand, it was to be noted that in later life most bacilli in the lungs were of human type, whereas swallowed bacilli were usually bovine. Also, in spite of much swallowed sputum, intestinal ulceration was comparatively rare. Calmette, however, maintained that in animals inoculated in the laboratory the lungs were always infected. Professor Cummins believed that both types of infection occurred. With reference to the third question, Professor Cummins quoted Bacmeister's experiments, in which the apices of rabbits' lungs were constricted by rings. When bacilli were injected intravenously there was a concentration of bacilli under the rings, but when bacilli were introduced into the respiratory passage no such concentration occurred, the lesions being general in the lungs. These experiments could not really be regarded as satisfactory owing to the stagnation of the circulation caused by the rings. He had himself observed groups of coal miners, some of whom had worked among silica, and found that in these latter men the lymphatic blockage was more effective at the apices than elsewhere, whereas normally coal dust was readily ingested by phagocytes.

THE ACTIVE PRINCIPLES OF ERGOT PREPARATIONS.

A MEETING of the Edinburgh Obstetrical Society was held on March 9th, with the President, Professor R. W. JOHNSTONE, in the chair. Professor A. J. CLARK raised the question "Do the pharmacopoeial preparations of ergot contain any active principles?"

Professor Clark said that he had no new discoveries to bring forward, but he wished to draw attention to certain well established facts. The history of ergot epidemics showed that ergot taken by the mouth produced toxic effects. The frequency of abortion during epidemics of ergotism probably led to the use of ergot in therapeutics. The outstanding therapeutic action of ergot was as follows. The drug when given by the mouth during labour caused increased force and frequency of pains within twenty minutes, and the intensified action was so powerful as to be dangerous if there was any mechanical obstruction. This was an unusually straightforward and easily recognizable therapeutic action. The active principles of ergot were unstable; indeed, the difficulty of obtaining reliable preparations of ergot was well known to Buchheim in 1859. It was, however, remarkable that there should be any doubt whether any given ergot preparation was active or inactive. The chemistry of ergot was for long a puzzle. In 1874 Tanret discovered the crystalline alkaloid ergotinine, which proved to be inert, but in 1906 Barger and Carr isolated the alkaloid ergotoxine which produced all the typical pharmacological actions of ergot and proved to be the hydrate of ergotinine. In 1922 Stoll isolated another specific alkaloid, ergotamine. The pharmacological actions of ergotoxine and ergotamine appeared to be identical. In addition to the specific alkaloids, ergot contained a remarkable medley of decomposition products of proteins. Tyramine and histamine, the amines derived respectively from the amino-acids tyrosine and histidine, had received most attention. These drugs produced remarkable and interesting pharmacological actions when given hypodermically, but had very little action when administered by mouth. The quantities of these amines in ergot were too small for them to be of any importance when ergot was given by mouth. The therapeutic action of ergot therefore depended entirely on the specific alkaloids, of which it contained 0.1 to 0.2 per cent. In 1907 Barger and Dale pointed out that since ergotoxine was insoluble in water the liquid extract of ergot could contain little or none of this active principle. In 1913 Carr and Dale criticized the pharmacopoeial preparations in detail and showed that they were all concocted in such a way as to lose nearly all the active principles. These criticisms were not affected by the discovery of the new alkaloid ergotamine, for this had similar solubilities to ergotoxine. In 1923 Professor Clark had performed a series of tests on the pharmacopoeial preparations of ergot made from ergot of known activity, and found that the processes of preparation involved the loss of 97 per cent. of the active principle in all cases except that of the ammoniated tincture, in which one-quarter of the active principle was retained. The properties of the ergot alkaloids had been recognized in other countries, and most of the foreign pharmacopoeias contained rational methods for making ergot preparations. Curiously enough, each revision of the *British Pharmacopoeia* since 1885 had made the ergot preparations as a whole worse than they were previously; since a new pharmacopoeia was likely to be prepared soon, the question was one of obvious practical importance. Why was it that obstetricians had accepted and apparently had used without much complaint for thirty years preparations of ergot which were found to be inert, when judged by chemical and pharmacological tests?

The Human Sex Ratio.

Dr. F. A. E. CREW then read a paper on the human sex ratio, in which he stated that the secondary sex ratio was nearly equality and seemed to constitute one of the many disharmonies which characterized the human species. One male was, in the matter of gamete formation, the equivalent of many females, and if the propagation of the race was the chief function of the species, then it would be better for the secondary sex ratio to be low unless polygyny was customary. It would seem that the habit of producing offspring had no relation to the present social needs of mankind, and that it was a phylogenetic legacy, being the expression of a mechanism which served well enough when the female elaborated as many ova as the male did sperms, but which had not been modified to fulfil the reproductive requirements of the present day. It had been established that the male in the human species was digametic, elaborating two kinds of sperm: one fertilizing an egg gave rise to a male, the other to a female. The female elaborated in respect of the elements of the sex-determining mechanism only one kind of egg. It could be shown that post-natally there was a significant sexually selective mortality, the sex ratio at birth of 104 males : 100 females being reduced through this selective elimination of the male to one of 55 : 100 in the 85-age group. It could also be shown that the sex ratio of stillbirth was higher than that which obtained among living offspring, and, further, that pre-natally this sexually selective mortality still operated, as was seen when the sex ratio of abortions was examined. Among the earlier abortions there were far more males, and the nearer to conception the higher was the sex ratio. It could be inferred, then, that the primary sex ratio, at the time of conception, was not less than 170 males : 100 females. Far more males than females were conceived, and far more perished pre-natally and natally; thus a secondary sex ratio of equality became established. It appeared that the male-determining sperms were either produced in greater numbers or else, and more probably, that they were more efficient in fertilization than were the female-determining sperms. Ante-natal care and child welfare clinics would help to save the males.

THE PROBLEM OF THE INEBRIATE.

AT a meeting of the Society for the Study of Inebriety on April 12th, Sir WILLIAM WILLCOX presiding, an address was delivered by Dr. R. B. BRANTHWAITE on the Inebriates Act, 1898.

Dr. Branthwaite said that the story of this Act, from its inception to its lapse, had much social and scientific interest; upon its administration was expended much determined effort and devotion. It involved, in relation to the class of persons for whose benefit the Act was designed, a study of the neuroses and psychoneuroses, not always in their lesser and milder forms. In the late sixties public opinion was impressed by the need for legislation for the control and treatment of inebriates. A Select Committee was appointed in 1872, but the fruit of its labours did not appear until the bill presented to Parliament in 1878, which provided for the establishment of institutions by private enterprise or philanthropic bodies for the reception of persons who voluntarily sought admission or were compulsorily committed on the petition of friends. Opinion, however, was not then ripe for compulsory powers, and in the Act which followed in 1879 these were dropped. It was the weakness of this Act that it dealt only with voluntary cases, although, no doubt, various constraints were employed, such as the threat of loss of employment or of matrimonial separation, to secure compliance. The Act, however, could not be regarded as a failure, for many persons obtained advantage by coming within its scope, and it was the knowledge of this advantage which later on encouraged the promoters of the Act of 1898. On his first contact as a young doctor with the administration of this Act, Dr. Branthwaite said he was specially instructed to regard habitual drunkenness as a disease, causing impairment of control and leading eventually to many attendant evils, such as crime and insanity. But after a few years' experience, during which he had seen a number of inebriates removed to mental hospitals, while others gave evidence of mental instability short of certifiable insanity, he revised his attitude, and thought of habitual drunkenness as a syndrome rather than as a disease. He saw it as the evidence of a fundamental neurosis or psychoneurosis. The temperance reformers of that period would not countenance such a notion, and there was a general reluctance at that time to consider the possibility of any mental or neurotic basis. After the Act of 1879 had been in force for some years, public attention was again drawn to the problem of the inebriate, and another departmental committee led to the passing of the Act of 1898, which made provision for the detention in reformatories of the worst class of inebriates. Even then there was great reluctance to accept the medical side of the question, and the majority of those who interested themselves in the management of the "reformatories" regarded those establishments as little more than substitutes for prisons in which inebriate persons could be retained for various periods and subjected to moral and religious influences. The Act authorized two classes of inebriates to be dealt with—criminal and recidivist. Some patients did benefit by the reformatory treatment, but the real cause which impeded development and ultimately led to failure was the realization that no sufficient benefit resulted to justify continuance of effort and expenditure. The Act was in operation more or less for twenty-two years; from first to last twelve reformatories were established, and 5,021 persons in all were committed for care and treatment. Everything that could be done centrally by the Home Office to bring the Act into operation was done wholeheartedly and with human sympathy. Of the cases committed to reformatories 17 per cent. proved to be definitely insane; 48 per cent. were unstable, subject to incipient insanity, mental defect, epilepsy, or various forms of neurosis or psychoneurosis; and 35 per cent. were apparently normal, or subject to so mild a degree of instability as not to justify an attempt at diagnosis. Of those in the first of these classes, some, when admitted to the reformatories, were found actually to be suffering from certifiable mental disease, while in the case of others who were in an ill-balanced excitable state on admission it gradually became evident that they could be dealt with only by certification. In the second class many of the types of mental disorder encountered differed only in degree from those seen in mental hospitals; cases of feeble-mindedness were common, and among them were many whose condition amounted to imbecility. A very large proportion of them would have come under the more modern definition of "moral imbecile"; they had a medium grade of intelligence, but were of a low moral type, not amenable, or only temporarily so, to good influences, asocial, callous in temperament, and inordinately selfish. The third group included persons approximately normal in conduct when deprived of alcohol, though many of them showed abnormal irritability, suspiciousness, shortness of temper, disregard of truth, and, most significant of all, dislike of regular work or anything savouring of monotony. It was from the persons in this third group that any good results of the reformatory system were forthcoming. The last case under the Act was committed in March, 1921, and the last certificate withdrawn shortly afterwards. This well meant effort to reform the criminal and recidivist inebriates of the lowest type had proved a failure, partly owing to difficulties beyond the control of those responsible for the administration, but mainly because the mental condition of most of the patients was such as to make reform impossible. Whether any better result would have followed the full recognition of the mental aspect of the problem and the application of the more modern methods of mental treatment it was hard to say. Many of the persons in the first and second group, and not a few in the third, were quite impervious to suggestion and incapable of self-help. With regard to the future, Dr. Branthwaite felt that the treatment of habitual drunkenness could not be distinguished from the treatment of mental defect or disorder in the most comprehensive sense of the term. This view of the subject should be fully realized by those whose duty it was to provide for children and young persons under the Mental Deficiency Act, and by all who were now advocating facilities for early mental treatment. He did not believe in the hereditary transmission of drunkenness, but only in the transmission of a predisposing constitutional peculiarity which might manifest itself in mental disorder, neurosis, epilepsy, or drunkenness. Drunkenness in successive generations was no evidence of its heredity, but only of a psychoneurotic strain.

Dr. A. E. A. CARVER said that the underlying psychoneurotic basis had been so far recognized by the Church of England Temperance Society that at the recent formal opening of its home for inebriates the invitation issued in the name of the Bishop of London spoke of a home "for the treatment of certain types of functional neurosis." Whenever an alcoholic or a drug addict was discovered and his addiction, so to say, was washed away, there remained a naked psychoneurotic.

Sir ARTHUR NEWSHOLME said that the figures given by Dr. Branthwaite were small in comparison with the population. In the years when the Inebriates Act, 1898, was being most fully administered the admissions to reformatories numbered only about 500 a year, which was 1 in 70,000 of the population, whereas the convictions for drunkenness in a year represented 1 in 400 of the population. No doubt those who were sent to institutions were of a malignant and almost incurable type, and to draw wide conclusions—as Dr. Branthwaite had not done—on a national scale from that small minority would be fallacious. The tendency of modern thought was to regard drunkenness as generally, if not always, the result of a psychoneurosis. But might not the facts be reversed in a number of cases, and habitual drunkenness, as a social phenomenon, arising from social habits, lead to the development of a psychoneurosis, instead of the psychoneurosis leading to the drunkenness?

Sir WILLIAM WILLCOX was inclined to agree with this view. A drug habit of any kind had a bad effect on the brain. One of the last pieces of work done by the late Sir Frederick Mott was to show that veronal and sulphonal and other habit-forming drugs caused actual change in the brain structure. Sir William Willcox thought that the development of a bad habit might lead to some actual brain degeneration, and thus a vicious circle was formed.

Reviews.

HOUSES AND HOMES.

ny well disposed person desiring to acquaint himself—as very well disposed person should—with the origins, progress, and present situation of the housing question in this country will find in *The Housing of the Nation*,[1] by Dr. F. E. FREMANTLE, M.P., with a preface by Mr. NEVILLE CHAMBERLAIN, a compendious and trustworthy guide. Dr. Fremantle, as one who in several capacities has devoted close attention to housing, speaks with admitted authority. He recalls that under the Hayes-Fisher and Addison schemes the Government offered housing grants to local authorities. The Chamberlain Act of 1923 was the charter of private enterprise, giving subsidies through local authorities to private builders. By the Wheatley Act of 1924 the annual grants of the Chamberlain scheme were increased in certain cases. For Chamberlain and Wheatley houses the current standards are that the house must contain a bath in a bathroom, that the density per acre must not exceed eight houses in agricultural areas or twelve elsewhere, and that floor space must range between 620 and 950 square feet for cottages and between 550 and 880 square feet for flats or bungalows. The housing campaign throughout the country has been productive of good results, in which the public utility societies have played a creditable part.

The so-called slum areas, those aggregations of worn-out houses, which screen rather than shelter the ineffectives of the community, have hitherto been less actively dealt with. Not, indeed, that they had escaped the notice of housing reformers, but a combined attack upon them, as Dr. Fremantle explains, has so far not been possible. In slum clearance the demand of slum-dwellers to be rehoused on the site is a common difficulty. They cannot be compressed into duly spaced cottages on the cleared ground, and they think tenement blocks cheerless, while their translation *en masse* to adjoining rural land raises the question of their transport to work. The tenement block, if not too high, is of local remedies perhaps the least unsatisfactory. The ultimate solution, however, is not a local one: it lies elsewhere, in the garden city, the essence of which "is neither its gardens nor its houses, but its factories and its workshops." If the people move out the factories must follow, and vice versa.

Among other topics discussed by Dr. Fremantle are employers and housing, building societies, the Octavia Hill method, costs and rents, housing and the countryside, forms of construction, and housing in Scotland. He takes the view that with the cordial co-operation of all concerned the housing of the nation within the next ten years should be placed on a sound and durable footing. Dr. Fremantle's book is for the general reader, but his words will appeal with special force to the members of his own profession, to whom the country will look for direction in a matter so nearly related to health. But it is not a matter of health alone. It is a question of home life and all it has ever stood for, from the *domus lacta* of Lucretius, with its glad welcome, to the "happy fireside clime" of a more recent age, the like of which men still are seeking to-day as a peaceful sanctuary in which their children may grow up in innocent content. In the crowded slum there is little room for either peace or innocence. "The effect on children," as the author says, "is such as neither the State nor humanity will tolerate." He rightly makes this statement with emphasis. It is fundamental. *The Housing of the Nation* is cordially recommended.

[1] *The Housing of the Nation.* By Lieut.-Colonel F. E. Fremantle, M.P., F.R.C.P., F.R.C.S., D.P.H. With a foreword by the Right Hon. Neville Chamberlain, M.P., Minister of Health. London: P. Allan and Co., Ltd. 1927. (Post 7vo, pp. xiv + 193. 6s. 6d. net.)

DISEASES OF THE INTESTINES.

Of recent years the advances in our knowledge of gastric function and disorder have been so considerable that the distal portions of the alimentary canal, apart from colonic stasis and ulceration, have had comparatively little attention. This is particularly true with regard to the small intestine, and Dr. A. P. CAWADIAS's book *Diseases of the Intestines*,[2] though it includes diseases of the large bowel, will help to restore the balance. It is based on experience in the gastro-enterological clinic of the Hôtel-Dieu Hospital, Paris, and at Athens, where until recently he was physician to the Evangelismos Hospital. It is not on the lines of an ordinary textbook, and while giving plenty of references to the literature, and providing new information and ideas, shows evidence of independent thought. In the preface a distinction is drawn between a symptom-complex, a syndrome, and a disease: a symptom-complex is defined as a series of symptoms and signs grouped together clinically without any consideration as to their relationship to a lesion or functional disturbance of an organ—for example, pain in the right iliac fossa, which may be due to appendicitis, salpingitis, tuberculous glands, and so forth; a syndrome, on the other hand, is regarded as a group of symptoms and signs corresponding to functional disturbance or a lesion of an organ—for example, appendicitis or ulcerative colitis; whereas amœbic colitis is a disease.

In a discussion of the anatomy of the parts the proto-duodenum or suprapapillary portion is separated on developmental and physiological grounds from the remainder or metaduodenum, which, it is held, belongs to the mid-gut. The intestinal dyspepsias from imperfect digestion of proteins, starches, and fats are next dealt with, and reference is made to kytarinorrhœa, or the diarrhœa occurring in some individuals when they take green vegetables and fruit, because there is insufficient bacterial digestion of cellulose. The inflammatory syndromes are divided into the diffuse—such as acute and chronic entero-colitis, typhlo-colitis, and [illegible] and the localized—namely, appendicitis, [illegible] and proctitis, acute and chronic. Muco-membranous colitis is described as a combination of spasm and hypersecretion of mucus due to overstimulation of the parasympathetic. Its source may be in the colon, but more often is elsewhere. The motor syndromes include organic and functional colonic stasis, stenosis of the small intestine, intestinal obstruction, and functional or extra-enteric diarrhœa (nervous, reflex, anaphylactic, and endocrine). Haemorrhoids and intestinal arteritis, constituting the vascular syndromes, and duodenal (protoduodenal) ulcer, intestinal cancer, and the clinical syndromes produced by intestinal worms, are all described.

Much stress is throughout laid on the pathology and on etiological diagnosis, and though in some respects the presentations of the subject-matter may appear novel and therefore strange, it is undoubtedly stimulating. The book is, of course, better suited for the advanced student than for the beginner.

[2] *Diseases of the Intestines.* By A. P. Cawadias, O.B.E., M.D.Paris, M.R.C.P.Lond. London: Baillière, Tindall and Cox. 1927. (Demy 8vo, pp. xiv + 299; 25 figures. 16s. net.)

NOSE, THROAT AND EAR.

THERE have recently been published a number of new editions of books on diseases of the nose, throat and ear in the production of which, for one reason or another, the original author has taken no part, and amongst this number is the fifth edition of BALLENGER's *Diseases of the Nose, Throat and Ear*.[3] It is interesting to observe the varying success with which these tasks of bringing up to date the work of another have been accomplished. It may be assumed, and is indeed the fact, that in each case the editor was well acquainted with the author, and undertook the work in a spirit of sympathy and even of admiration. It is nevertheless impossible for another to tell how the opinion of an author might have been altered, how later experience might have affected his judgement, and what importance he might have attached to contemporary work and writing. It will generally be the rule, therefore, that the less the original is altered the better, and that if much change is really required it would be wiser to sit down and write a new book, though this might be fairly based on the old one. The latest edition of Ballenger's textbook, which has a well established reputation, has

[3] *Diseases of the Nose, Throat and Ear, Medical and Surgical.* By William Lincoln Ballenger, M.D. Revised by Howard Charles Ballenger, M.D. Fifth edition. London: H. Kimpton. 1925. (Med. 8vo, pp. ix + 1080; 551 figures, 32 plates. 42s. net.)

undergone few alterations, but those that have been made are thorough. For example, the new chapter on asthma, hay fever, and the related types of rhinitis is particularly good. As before, the section dealing with the ear is by far the best part of the book. Although the arrangement of the various parts is not very good, it is a brilliant exposition of aural surgery, and forms a remarkable contrast to the futile discussion on cancer of the larynx by which it is immediately preceded. If another edition should be called for this portion should be subjected to drastic treatment, if not total extirpation. A careful and detailed account is given of the important subject of the accessory sinuses, and it is in the regions of the ear and the nose that the author is at his best. The book, however, has the advantage of including rhinology, laryngology, and otology in one large volume on an exhaustive scale, and will therefore meet the constant demand for a work of such design; its continued popularity is assured.

The seventh volume of the *Handbuch* on diseases of the throat, nose and ear,[4] edited by DENKER and KAHLER, contains the second part of the section on diseases of the ear, to which three volumes are being devoted. The material in the first part (Volume VI), which contained a general review of otology, was better arranged than that in the earlier volumes dealing with laryngology and rhinology. The new volume begins with diseases of the external ear by Dr. Oertel of Düsseldorf, and follows the usual course, ending with tumours of the auditory nerve by Dr. Mann of Dresden, who has naturally based his article largely on the work of Dr. Harvey Cushing. The article on oto-sclerosis is by Professor Brühl, whose name carries much authority in this country, but it is remarkable that no reference is made to the work of Dr. Albert Gray. More attention is paid to fixation of the stapes in the oval window than is now usually accorded by British authorities. The article on facial paralysis, which includes an account of the operative measures for its relief, is purely conventional and contains no fresh suggestions. There is an excellent account of inflammation and suppuration of the labyrinth by Professor Hinsburg, who reviews the surgical treatment, while Professor Alexander deals with the non-suppurative affections of the inner ear. In spite of the faults pointed out, this volume is more satisfactory than its predecessors. The eighth volume of the handbook, which is Part III of the section on diseases of the ear, begins with a discussion of the intracranial complications of aural disease. The statistics and pathology are expounded; though treatment is not neglected, this part of the subject might from the practical standpoint have been more fully illustrated. The few illustrations other than pathological mainly depict violent attacks on the jugular bulb of doubtful justification. This paucity runs through the volume, but it is in this part that ample illustrations are really essential. Thrombosis of the cavernous sinus is dismissed with unexpected brevity. There follows a section on forensic medicine in relation to diseases and injuries of the ear. The academic character of the work is shown by the allotment of about two hundred pages to deaf-mutes and school children, whilst all the intracranial complications are included in about two hundred and sixty. The concluding articles deal with military service, malingering, and life insurance respectively. All the subjects treated in this volume lend themselves either to pathological or statistical researches, and in these respects, especially the latter, full information is supplied.

RADIOLOGY.

DR. H. A. COLWELL and Mr. C. P. G. WAKELEY, in the preface to their book entitled *An Introduction to the Study of X-Rays and Radium*,[5] insist that it is to be taken to be no more than the title indicates—namely, an introduction. It is based upon a number of demonstrations given to students preparing for their final examinations, and is not intended to be in any way a complete textbook. Each of the twelve chapters is practically complete in itself, and has no particular connexion with those preceding or following it. There are also several appendixes, dealing, among other subjects, with fundamental and derived units, with electrical terms, with index notation, and with the ossification and epiphyses of bones. The main portion of the book deals with radium and *x* rays from all points of view other than those of actual use in diagnosis and treatment, with the exception that we are given two short chapters on certain forms of *x*-ray examination, and on *x*-ray and radium therapy. These are so short and incomplete that they are of little or no value, and it seems a mistake to have included them. We have nothing but praise for all the rest of the book; it will undoubtedly be of value to students, and more especially to those who are proposing to take one or other of the diplomas in radiology and electrology.

Dr. WILLIAM COTTON of Bristol, one of the pioneers in radiology and an authority on the stereoscopic image and on the exact meaning of *x*-ray shadows, has recently sent us an illustrated pamphlet entitled *Perspective in Relation to X-Ray Interpretation* (A Study in Apperception). It was communicated to the International Congress of Radiology held in London in 1925, and sets forth the author's opinions on a very difficult subject—opinions which, in some instances at any rate, are not in accord with those of most radiologists. At the same time there is undoubtedly a good deal of truth in what he has to say as regards the formation and the exact interpretation of the radiographic image; both are matters which many are apt to consider as of no particular importance and somewhat obvious. As Dr. Cotton observes, there are many pitfalls in interpretation due to non-appreciation of the manner of the formation of an *x*-ray picture, and we are quite in accord with his remarks on errors which are possible in the estimation of distances, and exact relative position, in cases such as the presence of metallic foreign bodies in the human body; stereoscopy is especially liable to lead to mistakes in this respect. The pamphlet is divided into a series of paragraphs which, under headings such as "Perspective," "The essential ambiguities of the *x*-ray picture," "The radiographic paradox," "Stereoscopy and pseudoscopy," and so on, make interesting reading, and we can commend its perusal to those interested in the subject.

An *Index and Handbook of X-Ray-Therapy*,[6] translated from the original German of Dr. ROBERT LENK of Vienna by Dr. T. I. CANDY, is in two sections. In the first, which is short, are discussed in general the action of *x* rays, prognosis, the effects of *x*-ray treatment, formulae for treatment, and so on. In the second section the conditions for which *x*-ray treatment can be recommended are arranged in alphabetical order, and a short account is given in each instance of the mode of action, the prognosis, the accompanying and subsequent effects, the necessity or not for adjuvant treatment, contraindications, and treatment formulae. The list of conditions said to be amenable to treatment is long and very comprehensive, and we cannot help thinking that the case for *x* rays is somewhat overdone when such conditions as gastric ulcer, gall-stone colic, badly functioning gastro-enterostomy, and such-like, are included and reported to be very favourably influenced. The book should be useful for reference to the general practitioner, and to the expert is not without its uses.

TREVES'S APPLIED ANATOMY.

SIR FREDERICK TREVES'S *Surgical Applied Anatomy*[7] probably still holds its own as the most popular work on the subject; as a compendious summary of the essential facts

[4] *Handbuch der Hals-Nasen-Ohrenheilkunde.* Herausgegeben von A. Denker und O. Kahler. Band VII/II, und Band VIII/III. Berlin: J. Springer; München: J. F. Bergmann. 1926 and 1927. (Sup. roy. 8vo, B.I. VII, pp. xii + 804, 282 figures, R.M.72; Bd. VIII, pp. ix + 666, 107 figures, G.M.60.)

[5] *An Introduction to the Study of X-Rays and Radium.* By Hector A. Colwell, M.B.Lond., and Cecil P. G. Wakeley, F.R.C.S.Eng., F.R.S.Edin. Oxford Medical Publications. London: Milford, Oxford University Press. 1926. (Demy 8vo, pp. xiv + 203; 37 figures. 10s. 6d. net.)

[6] *Index and Handbook of X-Ray Therapy.* By Dr. Robert Lenk. With a foreword by Professor Holzknecht. Translated by T. I. Candy, M.B., B.Ch., D.M.R.E. London: Milford, Oxford University Press. 1926. (Cr. 8vo, pp. xv + 121. 6s. 6d. net.)

[7] *Surgical Applied Anatomy.* By Sir Frederick Treves, Bt., F.R.C.S. Eighth edition, revised by C. C. Choyce, C.M.G., C.B.E., M.D., F.R.C.S.Eng. London: Cassell and Co., Ltd. 1926. (Fcap. 8vo, pp. x + 727; 162 figures, including 66 in colours. 14s. net.)

of surgical anatomy it has, so far as we know, no equal, and it has one feature which is generally conspicuously absent in most summaries, in being eminently readable. It is now in the forty-fourth year of its existence and in its eighth edition. The revision for this edition has been undertaken by Professor CHOYCE, who has been careful not to interfere with the general character of the work, while making such alterations as were absolutely essential in order to bring the subject matter up to date. Since the volume is one which the student will be wise to have near at hand, size becomes a matter of importance, and Professor Choyce has succeeded in practically maintaining its original dimensions, having added only a few pages, for which illustrations are mainly responsible.

In a book of this kind figures are introduced less as mere illustrations than as explanatory of the more complicated and less familiar details of the text. For instance, the average student's knowledge of the cervical sinus would probably be assisted by a diagram affording some notion of its relation to ranula. Apart from new figures, a revision of the older illustrations has been undertaken and a considerable number replaced by better ones. A certain amount of rearrangement of the text has been deemed advisable, with the object of improving the logical sequence of the subject matter. Among the more important additions we notice a description of the structure of the teeth and of their development, and a paragraph on odontomata. The treatment of femoral hernia has been redescribed, and the stages of the operation by the inguinal route are given in detail. In the eight years that have elapsed since the issue of the last edition the advances in gastric surgery have rendered necessary a considerable enlargement of the account of the various operations on that organ; and the increase of our knowledge of the mechanism of micturition, mainly due to the researches of Barrington, have necessitated the redescription of that process. With these and many minor additions, the book practically remains the same, and will doubtless retain its well deserved popularity.

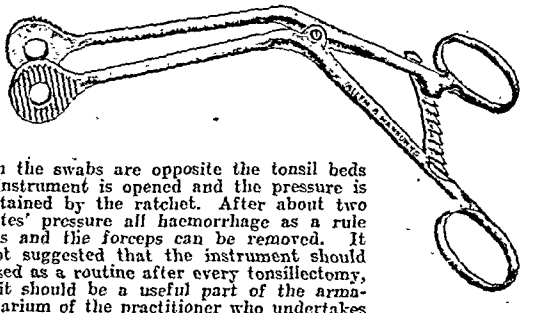
NOTES ON BOOKS.

DR. C. F. WHITE, assistant lecturer in sanitary science in the University of Liverpool, has produced a little book, *Aids to Sanitary Science and Law*.[8] It is as good an example of clear and exact thinking upon the theory and practice of sanitation, so far as this can be expressed upon the printed page, as is the Port of Liverpool, of which he is one of the medical officers, an example of excellence in the practice of port hygiene. There were formerly in the series to which it belongs two smaller books, one on sanitary science and another on sanitary law, but the volume before us is new. It will be found useful by candidates for the certificate of the Royal Sanitary Institute and Sanitary Inspectors' Examination Joint Board, and by medical students both before and after studying one of the larger textbooks, to provide first an introduction to the subject and later a means of rapid revision. It is tersely written, and the last section, that on sanitary law, is of the order that would be of use to every general practitioner, for he will find in it an account of the rights and obligations of the local authorities with which he has so often to do. Dr. White is to be congratulated upon the success of his effort to bring so much within a small compass.

Whatever views may be held about the nature of the "bacteriophage" there is no doubt of the interest of the subject, and therefore we are glad to have the writings of Dr. D'HERELLE, the discoverer of the principle, in an English translation.[9] The kingdom of the ultra-microscopic viruses and ferments is the growing point of bacteriology, and perhaps of biology in general. Within the last four years more than six hundred individuals have written articles or books about the d'Herelle phenomenon, contributing further experiment or criticism. Probably no subject has created so much bewilderment in the bacteriology laboratory in its brief history as the conflicting opinions on the nature of the transmissible lytic agent. Whether or not Dr. d'Herelle's restatement of his position will convince the dubious remains for the future to show, but disciple and critic alike will welcome this book, as will also the increasing numbers of the curious who ask "What is the bacteriophage?"

[8] *Aids to Sanitary Science and Law.* By C. F. White, M.B., Ch.B., D.P.H., D.T.M. London: Baillière, Tindall and Cox. 1926. (*Fcap. 8vo*, pp. viii + 316. 3s. 6d. net.)

[9] *The Bacteriophage and its Behavior.* By F. d'Herelle, M.D. Translated by George H. Smith, Ph.D. London: Baillière, Tindall and Cox; Baltimore: The Williams and Wilkins Company. 1926. (*Med. 8vo*, pp. xiv + 629; 6 figures. 36s. net.)



The Temple Press continues to produce new editions of its successful little *Cycling Manual*.[10] Nor is this surprising, since it is estimated that over six million people in this country ride bicycles. In the seventh edition, compiled and illustrated by the staff of *Cycling*, everything that the bicyclist should know about the construction of his machine and its care and upkeep has been brought together. He is even told how to breathe, how to keep fit, and what he should eat and drink.

[10] *Cycling Manual.* Compiled and illustrated by the Staff of *Cycling*. Seventh edition. London: Temple Press, Ltd. 1927. (*Pott 8vo*, pp. 114; illustrated. 1s. net.)

PREPARATIONS AND APPLIANCES.

A Method of Applying Pressure to Tonsil Beds.

DR. J. L. CYRIL DOYLE (London, W.1) writes: I have designed the forceps illustrated here to apply pressure to both the tonsil beds simultaneously. Its principal use is in cases when rather profuse haemorrhage occurs after tonsillectomy by a guillotine. The two swabs (previously attached to the free end of the forceps) are soaked in adrenaline and the instrument inserted in the mouth.

When the swabs are opposite the tonsil beds the instrument is opened and the pressure is maintained by the ratchet. After about two minutes' pressure all haemorrhage as a rule ceases and the forceps can be removed. It is not suggested that the instrument should be used as a routine after every tonsillectomy, but it should be a useful part of the armamentarium of the practitioner who undertakes tonsil operations, and should be taken with him when he operates, and used if the haemorrhage is at all profuse. The instrument is bent at an angle of 145 degrees; thus it can be used with convenience, whether the surgeon operates with the patient in the lying or the sitting position.

I am much indebted to Mr. Nicol Rankin for criticism and for testing the utility of the instrument. It is manufactured by Messrs. Allen and Hanburys Ltd., Wigmore Street, W.1.

A Glass for the Occlusion of One Eye.

Dr. Bernard Chavasse, M.B., B.Ch.Oxon. (Lecturer on Ophthalmology in the University of Liverpool), writes: The use of ground glass for the purpose of occluding one eye has three chief disadvantages: it is dazzling, very unsightly, and does not permit vision of large objects. The ideal occluding glass will therefore be free from dazzle, will allow the wearer's eye to be clearly visible through it, and will reduce the visual acuity of this eye to 6/60 and J.10, or to 1/60 and J.20, as may be prescribed by the surgeon. Such "one-way" glasses have been made for me, and I find that they form a valued addition to my trial case. This glass is an irregularly rolled plate glass, ground plano on one surface, down to any desired thinness. The effect of the irregularly rolled surface is to confer an arranged degree of very irregular astigmatism. Such a glass if laid on a sheet of paper permits vision through it of the smallest print; but if held to the eye no distinct vision is possible, either of near or of distant objects. When worn in spectacles the eye is clearly seen, but the eye sees so little that there is no desire for binocular vision; on the other hand, large, and especially moving, objects (as, for example, traffic) are visible.

The indications for the use of such a glass are, broadly, where, although there is fair or good acuity in each eye separately, the eyes cannot be used together; as in cases of weakness or paralysis of an external muscle, incorrigible insufficiency of convergence (as in post-encephalitic cases), and cases of anisometropia, as when a cataract has been successfully removed from one eye while the other still has good sight. As a rule, it will be best to start with the more pronouncedly occluding glass (1/60, J.20), and later to proceed to the other (6/60, J.10), when some psychical suppression has been developed. But if in doubt as to whether the glass in place is sufficiently occluding, the further addition of a 4-degree prism base up or down will decide the matter; for if the addition produces no discomfort the occluding glass must be adequate.

The glass is obtainable from Theodore Hamblin, Ltd., 15, Wigmore Street, London, W.1, and Rayner and Keeler, Ltd., 9, Vere Street, Cavendish Square, London, W.1.

Fine Adjustment Screw for the Sphygmograph.

Dr. Edgar F. Cyriax (London, W.1) has devised a fine adjustment screw which can be fixed to sphygmographs and polygraphs. It is brought into use after the fixation screw has been tightened. By its means the pressure of the apparatus on either side of the radial artery can be finely adjusted independently of the pressure of the pad on the artery; the observer, it is stated, is thus enabled in a few seconds to obtain the best excursion of movement from the recording needle. The screw may be obtained from Messrs. Arnold and Sons (John Bell and Croyden, Ltd.), 50-52, Wigmore Street, W.1.

British Medical Journal.

SATURDAY, APRIL 23RD, 1927.

SPINAL ENDOTHELIOMA.

THE current number of the *British Journal of Surgery* contains an able article by Mr. J. R. Learmonth on endothelioma, or, as he prefers to call it, lepto-meningioma, of the spinal cord. Although this kind of tumour is of somewhat rare occurrence, it is well worth a careful study, because, if treated early enough, its removal is not usually a matter of much difficulty and the results are most satisfactory, while, if untreated, it is uniformly fatal. The growth is non-malignant, and as it is generally possible to remove it within its capsule, there is little danger of recurrence from incomplete removal. The success of the operation depends mainly on the date at which it is undertaken and the type of compression exerted on the spinal cord, a deep localized indentation producing more permanent damage than a more extensive flattening. In early cases, where the conducting paths have not suffered severely, return of function is usually rapid and complete, and in general it may be said that where paralysis has been present for less than twelve months, at least some return of function may be confidently expected. In some cases improvement is apparent at once, but it has been known to show itself after so long an interval as eighteen months after the removal of the tumour.

Mr. Learmonth's article deals with the subject from every point of view, and is, in fact, a treatise on endotheliomas of the cord, handled in a thoroughly practical manner. His account of the clinical features of the disease is especially worthy of praise. Each symptom is made the subject of intimate discussion, and the reasons for its occurrence and its anatomical basis are explained with admirable clearness and completeness. Similarly with the subject of diagnosis: the direct and the accessory means of diagnosis, such as the examination of the cerebro-spinal fluid and the radiography of the spinal column after the introduction of air or lipiodol, are fully explained. A matter of some difficulty in connexion with the diagnosis of these tumours depends on the fact that they are by no means the most frequent type of growth affecting the spinal cord. Apart from such lesions as the specific granulomata, tumours affecting the surrounding structures have to be taken into consideration equally with the endotheliomas as causes of compression. Schlesinger found in 400 cases of tumours of the spinal cord that no fewer than 107 were sarcomas and 27 gliomas or gliosarcomas, while the endotheliomas numbered only 24, or 6 per cent. of the total. This fact notwithstanding, the author has done well to limit his research to a single type of tumour, since it is along such restricted lines that neurological surgery is likely to be most surely advanced.

In an interesting historical introduction the author has traced the change of view that has occurred in recent years with regard to the nature and origin of the endotheliomas, whether of the cerebral dura mater or of the membranes of the cord. The small fibrous and gritty tumours, usually called psammomas, which are not uncommonly found springing from the cerebral dura, and, unlike the spinal growths, are of little practical importance, are usually considered to arise from the proper tissue of the dura. For some years, however, Bland-Sutton and Schmidt have held the view that they arise from buds or protrusions of the soft membranes into the dura—a view based mainly on the fact that they are met with chiefly in the same situations as the arachnoidal villi. This opinion has recently received some support from Mallory on the histological side. It has further been generally held that the proper cell elements of these tumours, the calcification of which causes their gritty character, are of mesoblastic origin. Considerable doubt has been thrown on this view by some recent observations of Harrison, which seem to point to an epiblastic or epithelial derivation of the soft membranes. Harrison excised a portion of the brain substance of *Amblystoma punctatum* with the adjoining neural crest—an epithelial structure—and transplanted it beneath the skin of the trunk. It was found that the brain tissue became surrounded with both soft membranes and dura. In a second experiment the brain substance was transplanted after careful removal of the neural crest, and in this case no soft membranes were formed, but dura alone. If these observations are confirmed there would seem to be no doubt of the epiblastic origin of the endotheliomas of the membranes of the central nervous system.

Mr. Learmonth has given a very careful account of the gross and microscopical characters of the endotheliomata, illustrated by a large number of good microphotographs; and he has appended to his article a complete bibliography from the year 1918 to the present time.

A BUDGET OF EXPEDIENCY.

MR. CHURCHILL'S third Budget is admittedly designed to meet a special non-recurring emergency, and should be judged on that basis. Usually a Chancellor's claim to approbation stands or falls by his exercise of foresight and provision for the distant as well as the more pressing requirements of the nation's finances. But there are occasions when a stop-gap Budget is justified, and there is a general consensus of opinion that this is the case this year. The coal dispute of last year, even more than the general strike which for a short time accompanied and overshadowed it, inflicted very serious damage, not only on the Exchequer, but also on the general industrial condition of the whole nation. Briefly, Mr. Churchill's task has been to repair the former as far as possible without retarding the recovery of the latter. In this dilemma he has had recourse to expedients which are ingeniously arranged to meet the emergency, but which would rightly have aroused hostile criticism if employed to meet a less abnormal situation. The permanent or semi-permanent additional taxation imposed covers a comparatively small proportion of the gap between anticipated needs and the normal yield of present taxes; the remainder is bridged by anticipating revenue, as in the case of the beer duty and income tax payable under Schedule A, and taking into use for the general Exchequer the special balance in hand hitherto held by the separate Road Fund.

This method of dealing with the situation has, of course, aroused opposition, and that not merely from those whose parliamentary privilege or duty it is to criticize and oppose. In such a case as this criticism is doubly armed: not only is the general scheme open to attack on the ground that it is unsound, lacking in the statesmanlike qualities of prevision and caution, but also on the special grounds that the particular

features of the scheme are open to specific objection. With regard to the former class of criticism—that the circumstances are not sufficiently abnormal and free from the liability of recurrence to justify methods applicable to a temporary emergency—one factor of the situation has been made clear by subsequent discussion, and that is that the country expects the Government to make it its business to see that the present financial situation does not recur. Apart from such a calamity as, for example, a war in China, the Government is expected to keep expenditure within such limits that when the next Budget is prepared it can be balanced, not only without any serious additions to taxation, but also without such adventitious aids as have now been employed. If the Government can achieve that object it will have justified its present general financial policy.

Turning to the specific means adopted, the two changes which have evoked most criticism have been the absorption of the Road Fund balances and the collection of eighteen months' property tax—or income tax assessed under Schedule A—in one year. Mr. Churchill's position with regard to the Road Fund is in theory not difficult of defence. If the income of that fund is in excess of expenditure it is reasonable enough that the Exchequer should have the use of the balance in hand, but only on the assumption that the change is not allowed to impede the proper and reasonable rate of expenditure on the objects for which the fund was specifically created. It seems probable that there may be such a tendency, and it is such apprehensions that have lent point and force to the objections raised against the change. There must be few sections of the community better qualified to speak of the importance to the general public of creating and maintaining good roads than that represented by our readers, and any risk of an arrest in the rate of improvement must be a matter of keen regret. Nevertheless, the circumstances are such as to justify a suspension of hostile criticism until the practical results can be more definitely seen.

The property tax change is justified on several grounds, as, for instance, that it is a reversion to the practice in force before the rate of tax was raised above 5s. in the £, and that in many cases the immediate payer passes on his burden to the landlord or mortgagee. These reasons are somewhat in the nature of special pleading. They are ingenious and they carry weight, but do not displace the cardinal fact, which is that one group of taxpayers are being asked to overtake a six months' tax so that the Exchequer can profit by the anticipation. Granted the necessity of some such special demand, perhaps it can be borne by the class selected as well as by any other. The discussion of these unusual features of the Budget may perhaps facilitate the passing of the provisions necessary to implement the increased wine and tobacco duties; indeed, these were generally anticipated, and have largely been discounted in advance. In such circumstances the British taxpayer's attitude is not infrequently one of relief that the fact is no worse than expectation.

The Chancellor's undertaking to simplify the income-tax system will probably evoke more general and permanent interest. Apparently he is endeavouring to reach the long-desired simplification in two stages. At present he is moving towards a simplified system of assessment, by which all income which is not taxable at the source will be assessed on the basis of the amount of the income of the previous year; when he arrives at that stage—that is, when the year 1928-29 is reached—he proposes to arrange for taxpayers to be able to make one declaration of income leading to one payment of income tax. Super-tax as such is to disappear and be merged into a surtax which shall be payable, not as at present on the basis of a separate declaration, but on an assessment based on the one declaration made for income-tax purposes. In such matters it is fairly safe to assume that time will show that a simplified system will bring its own particular inconveniences with it; at present we are content to join in the general chorus of applause for the Chancellor's intentions, and of hope for his success in an admittedly difficult field. Every Budget comes up for judgement after an interval of twelve months, though when it embodies a scheme for future taxation a remand for further evidence is sometimes justified. The present Budget is devised to meet a temporary but serious difficulty, and is therefore based on an implied promise or expectation that it shall not recur. The judgement at the bar of reality next year will therefore be definite in a special degree, and we hope that we may then be able to congratulate Mr. Churchill on the vindication of his policy. If we find ourselves in that pleasant position it will be because the Government has brought an unusual amount of determination to bear on securing economy of administration at each and every opportunity throughout the year.

POST-MORTEM EXAMINATIONS IN RURAL DISTRICTS.

In the wilds of Essex life still retains much of its primitive charm, but administration may be too primitive, and an instance is afforded by some of the conditions under which *post-mortem* examinations have sometimes to be performed. Dr. Christmas of South Benfleet at a recent inquest appealed to the coroner to press for the erection of a mortuary; he explained the situation more fully to the *Westminster Gazette*, and from the report in that newspaper it appears that the place where bodies have to lie is a disused stable attached to one of the oldest inns in Essex, and adjoining the main road; the place is full of dust and rubbish, and cobwebs hang in clusters from the roof. The *post-mortem* table is a shutter on two trestles, and light is obtained only by leaving the stable door open. An old stable bucket filled with water and a little hot water supplied by the landlady of the inn completes the equipment. It appears that requests for better conditions have been made on many occasions to the local authority, the Rochford Rural District Council, and for many years the rural council is stated to have promised to build a mortuary; but promises materialize slowly in primitive spots, even when barely thirty miles from London. By a coincidence we have received this week from Dr. Cyril Helm of Great Horkesley, Colchester, a letter strongly expressing his view that "the Ministry of Health should give its attention to the conditions under which *post-mortem* examinations are made in rural districts. At the present time conditions are no better than they were in the Middle Ages, and a *post-mortem* examination may have to be carried out in some extremely dark and dirty barn, shed, or garret. Done under such conditions an examination is not only useless, but is also offensive to common decency." To remedy this state of things he expresses the opinion that "it should be compulsory for all *post-mortem* examinations to be done in a proper room in the nearest big town, and that a trained attendant should be provided by each county to assist. Unless the cause of death is very obvious it is almost impossible to find it under the conditions" described. That reform is necessary everyone will agree, and we are glad that the *Westminster Gazette* has taken the matter up and brought it to the notice of the public.

Whether Dr. Helm's suggestion is the best remedy we are not prepared to say, but in these days of rapid motor transport it would seem to be feasible for the doctor to get quite quickly to the nearest town to carry out the instructions of the coroner.

DEATH REGISTRATION AND CREMATION.

IT may not be untimely to remind the profession that two Acts passed during the last session of Parliament, the Coroners (Amendment) Act and the Births and Deaths Registration Act, come into force, the former on May 1st and the latter on July 1st next. The provisions of these Acts were discussed in a leading article on December 25th last (p. 1233). Under the Coroners Act increased fees will be payable to medical men conducting *post-mortem* examinations or giving evidence in connexion with inquests; and the Home Secretary is empowered to "make rules for regulating the practice and procedure" in these connexions. These regulations have not yet been issued, but it is understood that they will be provisionally made by the end of the present month. They are of some importance to the profession. In connexion with the Births and Deaths Registration Act, inquiries are proceeding with regard to a possible international nomenclature of the causes of death, and with regard to some alteration of the form of certificate of death to get rid of the terms "primary" and secondary" as used on the present certificate, with the intention of securing a more uniform and precise statement of the causes of death, whether immediate, more remote, or merely contributory. It is relevant to call attention to some recent publications of the Cremation Society, especially to a pamphlet by Lord Salvesen, P.C., K.C., on "The medico-legal aspect of cremation." The Home Office regulations relating to the disposal of the dead by cremation were issued in a revised form in 1920. The requirements under these regulations, which must be complied with before a body is cremated, are very stringent, possibly even overstringent if cremation is to be preferred and encouraged as a public health measure to replace burial. For the detection of foul play they would appear to be complete, for they would almost inevitably reveal any suspicious circumstances attending the death. It is almost inconceivable that, say, a poisoner would choose this method of disposing of the body of his victim rather than the method of burial, which scarcely affords adequate safeguards in all cases against the body being put under the earth without the cause of death having been accurately ascertained. Further legislation is still needed to carry out the policy of the British Medical Association in this regard. The relatively large acreage in the neighbourhood of towns required for burial grounds is also a matter of importance at the present time, when space for games and recreations, both for school children and adults, is so difficult to obtain. Lord Salvesen calls attention to a further requirement of the existing law, that no crematorium shall be constructed within fifty yards of any public highway. An ordinary cemetery may adjoin a public road; and a modern crematorium need not be either a source of nuisance or an eyesore. This legal provision in practice often makes it almost impossible to find a site for a new crematorium.

THE LAST CENSUS: ENGLAND AND WALES.

THE General Report on the Census of England and Wales, 1921, published on April 19th,[1] completes the series of official volumes issued in respect of that census. The population numbered rather more than 37¾ millions, 649 to each square mile on the average, or about an acre a head—a density greater than that of any country in the world for which statistics are available. Though an increase has been recorded at every census, the rate of growth between 1911 and 1921 was smaller than in any preceding decade, for which the adverse effect of the war must be accounted mainly responsible, both in the losses amongst men of military ages and in the unprecedented fall in the birth rate. It compares favourably in this respect, however, with other European belligerents, whose populations generally advanced at a much slower rate or even declined. Nearly 80 per cent. of the population were enumerated as living in urban areas, and of these practically half were found in comparatively dense aggregates represented by the forty-six towns each containing more than 100,000 persons. The rate of growth of the smallest towns is above the average for the whole country, and the rate appears to increase as the towns get larger, until the populations reach a figure in the neighbourhood of 100,000. After this the rate of increase tends to slacken, suggesting that 100,000 roughly marks a limit of effective aggregation beyond which the advantage of further accretion begins to be offset by counterbalancing disadvantages. Prominent amongst the towns which showed little increase or which decreased during the decennium are those associated with the textile industry in Lancashire and Yorkshire. Notwithstanding the house shortage, the total number of rooms available for habitation is greater in relation to the population than it was in 1911. Families are, on the whole, smaller than they were ten years ago, and since small families are able to command a higher standard of housing than the larger, they have absorbed a greater share of the available house room than they had in 1911. To this change and to the uneven distribution of accommodation throughout the country the present situation is believed to be in large measure due. The proportion of population living under the overcrowded conditions of more than two persons in a room was 9.1 per cent. in 1911 and 9.6 per cent. in 1921; in Northumberland and Durham 30 per cent. of the population are in the overcrowded category, while in London the proportion is 16 per cent. The depletion of males at early adult ages and the deficiency of very young children of both sexes are clearly shown in the age curves. The losses at the younger ages automatically result in a general ageing of the population as a whole, a change which has been further accelerated by the improved vitality of the middle-aged registered in recent years. The war has been responsible for a greatly increased disparity in the numbers of the two sexes, the surplus of women now exceeding 1,700,000, as compared with less than 1,200,000 in 1911. Amongst the marriageable population the disparity is greater, and between the ages of 30 and 35 there are 1,470 unmarried females for every 1,000 unmarried males. In a section on occupations in different parts of the country it is shown that a very marked decrease in child labour has occurred. The number of aliens has fallen from a proportion of 790 per 100,000 total inhabitants in 1911 to 602 in 1921, though immigration from Belgium and the United States of America has increased. More than half the total of foreigners were enumerated in the county of London, and nearly one-third of these were in the metropolitan borough of Stepney. A new dependency and orphanhood section, primarily designed to provide data for the framing of the national scheme of widows' and orphans' pensions and allowances, contains a survey of the sizes, age constitution, and distribution of families in relation to their parents; the average for all married men was only 1.27 children apiece. More than 43 per cent. of the married men returned no children under 16, while in another 23 per cent. there was one child only. Miners returned the largest families on the whole, but their average was only 1.82 for each married man, while in the case of professional men the average was 0.90.

CONCERNING ANEURYSMS.

IN the third Gordon Bell Memorial Lecture[1] Professor Oskar Klotz of Toronto summarized the results of some twenty years' work on aneurysm and the diseases of arteries. In dealing with the history of aneurysm he makes the interesting point that though Galen, Actius, and Antyllus described the condition, it chiefly affected the peripheral arteries and was traumatic in origin until syphilis, whether imported from America by Columbus's crews in 1493 or not, became epidemic in Europe at the end of the fifteenth century, when aortic aneurysm occurred with a frequency such as had never before been known. The steps by which the etiological importance of syphilis was established are traced in detail. The anatomical distribution of luetic aortitis is fully described; it is most frequent in the ascending part of the arch, below which it diminishes; there is often an abrupt transition from a diseased to a healthy vessel at the level of the diaphragm, as if the virus met with some difficulty in traversing the lymphatics at this point; the commonest spot for syphilitic disease of the abdominal aorta is the coeliac axis, where there is a rich network of lymphatics. The difficulty of therapeutically eradicating the *Treponema pallidum* from the aortic walls is compared to that in parenchymatous syphilis. It is pointed out that syphilitic disease of the cerebral arteries is less frequent now than it was reported to be some years ago, and probably many cases of miliary aneurysms (which by a curious misprint appear as "military" aneurysms) were wrongly regarded as syphilitic. Fusiform aneurysms are almost always due to syphilitic aortitis, and can now be recognized by x rays before the symptoms—usually of aortic incompetence and cardiac failure—became evident. In his discussion of aneurysms resulting from acute infections, Professor Klotz records eleven cases under 15 years of age, three being associated with endocarditis (two rheumatic), two tuberculous, two congenital cirsoid, a congenital aneurysm of the sinus of Valsalva, and three false aneurysms from trauma. Wars make traumatic aneurysm more common, but popliteal aneurysms—formerly, as shown by Crisp's statistics seventy years ago, especially frequent in cavalry and post riders from injuries in the saddle—are curiously rare now. Arterio-sclerosis of non-luetic origin is comparatively unimportant as a cause of aneurysm, except of the dissecting aneurysms, which are usually due to senile changes, and may be called "the aneurysms of old age." This interesting lecture closes with a summary of our knowledge of aneurysms in animals, from which it appears that, apart from parasitic worm infections in dogs, there is not any disease in the lower animals which specially affects the arterial tissues in the way that syphilis does in man.

RHEUMATIC MANIFESTATIONS IN CHILDHOOD.

AN illustration of the widening interest which is being taken in rheumatic heart disease was afforded by the invitation extended by the Royal Sanitary Institute to Dr. Dingwall Fordyce to read a paper on rheumatic affections in children at a sessional meeting on April 8th. Dr. Fordyce emphasized the need of focusing attention on this problem with a view to inaugurating a campaign, and referred to the stimulating value of the Report of the Science Committee of the British Medical Association published last July. He said that although the etiology of acute rheumatism in children was still obscure, it was generally agreed that the disease was a definite entity, and that there was a common and insidious form which tended to cause mitral stenosis. In contrast with such infections as scarlet fever and diphtheria, rheumatism was characterized by the existence of a recognizable diathesis—a most important consideration from the prophylactic standpoint. Moreover, during the first two years of life the specific group of symptoms did not occur. This indicated that either there was an unsuspected infantile rheumatic infection, or that the first two years were most important in determining the development of the rheumatic diathesis. Carditis, the dreaded sequel of rheumatic infection, commenced usually in childhood. Dr. Carey Coombs, dealing with 600 cases of cardiac rheumatism, had found that the onset occurred most often between the ages of 5 and 15. Childhood, then, was the period of danger, but if properly guarded the prognosis was good. At this age the patients were usually mentally alert, so that the educational as well as the physical prognosis was distinctly promising. The prevention of rheumatism comprised all measures which conduced to healthy infancy and childhood, coupled with the recognition of a particular diathesis; the transitory ailments of this period should be completely cured, and all foci of infection, such as carious teeth, tonsils, and adenoids, must be eradicated. In addition to these measures, suitable mental environment and training were necessary. Child welfare work, by filling gaps in the home life and serving to co-ordinate the various official agencies, was the first step in the prevention of rheumatism, its value lying in its far-reaching educative and moral effects. But many gaps in this educative sphere still needed bridging. Up to the age of 5, despite the existence of numerous clinics, the child was almost solely under home control. If definite signs of rheumatism occurred at this, the usual age for beginning school life, there must be full and effective treatment. Rest, the most powerful agent in prophylaxis, should be properly valued and rightly administered. Mentally active children must not be unduly stimulated. Prolonged and close medical supervision was necessary, and also closer correlation of education and treatment. Intimate co-operation between the various medical and other agencies dealing with children would lead to medical practitioners becoming more expert; research would be facilitated and the treatment of patients be greatly improved. Dr. Fordyce deplored the fact that child welfare work was more dependent on sentimental considerations and the appearance in the lay press of highly coloured accounts of laboratory discoveries than on clinical medicine. This could be redressed by better co-operation of the medical and lay agencies concerned. The dentist, rhinologist, and laryngologist should be more often consulted, and the urgent call for more hospital beds for children undergoing such minor operations as tonsillectomy must be met. Increase in the number of beds available for rheumatic and cardiac patients was also essential. Special cardiac clinics and the provision of vocational training for cardiac patients were much needed; even from the scholastic viewpoint a closer co-operation between general practitioners, hospital physicians, and school medical officers was highly desirable.

OPHTHALMIC HOSPITAL OF THE ORDER OF ST. JOHN OF JERUSALEM.

THE British occupation of Palestine, by facilitating travel in that country, had added much to the work of the Ophthalmic Hospital of the Order of St. John of Jerusalem. The inauguration three years ago of a series of ophthalmic clinics made the work more widely known, and the improvement in the roads and railways, together with the increased numbers of motor cars, enables patients to travel considerable distances for treatment. It is now being found very difficult to deal with the large crowds who apply daily for treatment. In his annual report for 1926 the warden of the hospital, Lieut.-Colonel J. C. Strathearn, M.D., states

that many previous records have been broken; 18,127 new patients were treated in 1926, as compared with 16,640 in 1925, 1,499 being admitted as in-patients and 4,234 operations being performed. In one day in September 628 cases were dealt with, the incidence of acute conjunctivitis being very high in this and the previous month. Trachoma is still very prevalent, and the bulk of the operative work was concerned with its treatment. A children's clinic was started in July. It was hoped to build an annexe to the hospital, and over £1,500 had been collected for this purpose, but difficulties arose in securing the site desired, and no progress was made last year. A house with garden has been presented to the Order, and this may possibly be used to accommodate some of the hospital staff and to provide a small dispensary. The urgently needed drainage scheme for the hospital awaits the laying down of a new sewer for the south-west part of Jerusalem. The six ophthalmic clinics instituted by the Palestine Government at Nablus, Tulkeram, Acre, Ramleh, Gaza, and Beersheba have been supervised by the staff of the hospital, and during the year under review dealt with 13,814 new patients, 2,684 operations being performed. During the visit to Jerusalem last spring of the Sub-Prior and other executive officers of the Order the warden of the hospital was invested as a Knight of Grace.

ANNUAL MEETING OF THE CANADIAN MEDICAL ASSOCIATION.

THE fifty-eighth annual meeting of the Canadian Medical Association will be held at Toronto from June 13th to 18th, in conjunction with the Ontario Medical Association, the Canadian Public Health Association, the Canadian Tuberculosis Association, the Canadian Society of Anaesthetists, and the Canadian and Ontario Radiological Societies. The scientific proceedings will include general sessions and a number of sectional meetings, the sections being: Anaesthetics; Eye, Ear, Nose, and Throat; Medicine; Obstetrics and Gynaecology; Pathology and Bacteriology; Pediatrics; Public Health; Radiology; and Surgery. The second Listerian Oration will be delivered on June 17th by Sir C. S. Sherrington, Waynflete professor of physiology at Oxford. Other visitors from Great Britain who are taking part in the conference include Sir G. Lenthal Cheatle, Dr. J. Strickland Goodall, Dr. A. L. Fleming, and Dr. S. Gilbert Scott, who will represent officially the British Medical Association. The Sections of Pathology, Radiology, Medicine, Anaesthesia, and Surgery will combine for a discussion of the gall bladder; and pathological demonstrations are to be arranged with special reference to the problems of the medical practitioner.

Nova et Vetera.

EUTHANASIA.

THE thesis has often been propounded that in cases of incurable and painful disease it should be permitted to the medical attendants, using their own discretion and subject to the consent of the patient's relatives, to terminate suffering swiftly and painlessly. Euthanasia is no new conception, nor can it be said that recent balancing of the pros and cons has revealed any fresh or more potent argument in its favour than those that have been advanced from time to time down the centuries. However ready they may be to agree to the proposition in the abstract, very few doctors, either alone or in council, would be prepared to accept the heavy responsibility which would be theirs were the "doping to death" of the hopeless case to become a recognized custom established with full legal sanction. This question has been debated in the past by men of diverse interests and of all shades of opinion. Sir Thomas More in *Utopia* has revealed his own quite definite view in these words:

"When any [Utopian] is taken with a torturing and lingering pain so that there is no hope of recovery or of case, the priests and the magistrates come and exhort them that since they are now unable to go on with the business of life and are become a burden to themselves and to all about them, so that they have really outlived themselves, they should no longer nourish such a rooted distemper, but should choose rather to die since they cannot live but in much misery; being assured that if they deliver themselves from their prison and torture, or are willing that others should do it, they shall be happy after their deaths. . . ."

Three hundred years later we find Lionel Tollemache, in his well known essay *The Cure for Incurables*, writing as follows:

"If a summary remedy could be applied to this suffering there would be the further advantage that persons of a morbid and brooding nature might gain confidence through life and that knowing that death would be deprived of its sting, they would have a sort of negative stimulus or (if I may so say) an anti-preventive to exertion. Then again, we must consider the friend who, besides the immediate suffering of nursing the sick ma often permanently impair their constitutions and nervous system and who moreover are thus exposed to a sort of moral suicide I mean they curtail their own powers of usefulness far more tha a dose of laudanum would curtail those of their dying friend. . . On the whole it cannot be doubted that the benefits resulting fron a change in the law would be simply enormous."

Thus have spoken the statesman and the philosopher o widely different ages. What of the poet? Joseph Severn the friend of Keats, who was with him at his lonely deat in a foreign land, has left the following passage on record:

"One day he broke down suddenly and demanded that this foreseen resource should be given him. The demand was for the phial of laudanum I had bought at his request at Gravesend. When I demurred he said to me that he claimed it as his own and his right, for, he added, with great emotion, 'As my death is certain, I only wish to save you from the long miseries of attending and beholding it. It may yet be deferred and I can see that you will thereby be stranded through your lack of resources and you will ruin all your prospects. I am keeping you from your painting and as I am sure to die, why not let me die now? I have now determined to take this laudanum and anticipate a lingering death while emancipating you.' As I still refused to let him have the laudanum he became furious . . . and yet in all this there was no fear of death, no want of fortitude or manliness, but only the strong feeling on my account to which he regarded himself and his dying as secondary."

Again, a quotation may be made from the memoirs of a famous musician, Berlioz:

"I have lost my eldest sister; she died of cancer of the breast after six months of horrible suffering which drew heartrending screams from her day and night. My other sister, who went to Grenoble to nurse her, and who did not leave her till the end, all but died from the fatigue and the painful impressions caused by this slow agony. And not a doctor dared to have the humanity to put an end to this martyrdom by making my sister inhale a bottle of chloroform. This is done to save a patient the pain of a surgical operation which lasts a quarter of a minute, and it is not had recourse to in order to deliver one from a torture lasting six months. . . . The most horrible thing in the world for us, living and sentient beings, is inexorable suffering . . . and we must be barbarous or stupid, or both at once, not to use the sure and easy means now at our disposal to bring it to an end. Savages are more intelligent and more humane."

In striking contrast to this we have the exactly contrary opinion of the great Napoleon recorded during a conversation at Elba with Lord Ebrington:

"I have often thought since on this point of *moral* and have conversed on it with others et je crois qu'au fond il vaut toujours mieux suffrir, qu'un homme finisse sa destinée quelle qu'elle soit. I judged so afterwards in the case of my friend Duroc, who, when his bowels were falling out before my eyes repeatedly cried to me to have him put out of his misery. Je lui dis, je vous plains, mon ami, mais il n'y a pas de remède, if faut suffrir jusqu'à la fin."

And now, in the third decade of the twentieth century, after a war beside which Napoleon's campaigns were mere skirmishes, this same question is being soberly debated in the public press by priest and layman, surgeon and physician, and no practical outcome in the way of revolutionary change in the practice of centuries is likely to be the result of it. If we were to draw any inference from the above quotations it would be that, whereas to the mind of the theorist, be he statesman, philosopher, poet, or musician, euthanasia commends itself as not only desirable but even necessary, yet to the man of action, the man most likely to be called upon to translate the theory into actual practice, the idea is almost abhorrent. That is very probably how it strikes the mind of twentieth century man also.

DUNEDIN, NEW ZEALAND.

(Concluded from page 740.)

THE SCIENTIFIC SECTIONS.

SECTION OF OPHTHALMOLOGY.

DR. A. M. MORGAN, President of the Section, delivered an address on the causes of concomitant strabismus. He thought that the theories of Donders and Worth did not explain why hyperopes sometimes had divergent squints and myopes sometimes had perverted squints, nor why vertical squints occurred. These theories also did not explain why all squints were not cured by a full correction of the refractive errors as, theoretically, they should be, nor why the patients might have a squint in any direction without any error of refraction at all. In his opinion the three causes of concomitant squint, in the order of their importance, were weakness of the fusion sense, heterophoria, and hypermetropia. The first only was essential, but must be accompanied by one of the others. The determining factor in the development of a squint was the relation between the desire for fusion and the effort needed to align the eyes correctly. If the desire for binocular vision was greater than the effort there would be no squint. If the effort was greater than the desire a squint would result. Hypermetropia played a very minor part in the causation of convergent squint. Myopia as an error of refraction had no part in the causation of divergent squint, though it might tend indirectly to exophoria in myopic eyes.

Dr. H. F. SHORNEY (South Australia) discussed the etiology and treatment of non-suppurative intra-ocular affections, including retrobulbar neuritis. He dealt with the etiology under the headings of affections of the teeth and gums, tonsils, and accessory sinus diseases, mentioning the frequency of infection of the optic nerve and nerve head in sinus affections. His experience pointed to the occurrence of a descending retrobulbar inflammation, accompanied as it not infrequently was by some inflammatory reaction of the nerve head, rendered visible by the ophthalmoscope. Other etiological points were: metabolic diseases, diseased organs producing altered chemical action from hypersecretion or hyposecretion, parasitic causes, infection from penetrating wounds, and endogenous infections. After describing the routine treatment of acute iritis, he gave details of the milk injection therapy. He reviewed the substances used in the treatment of intra-ocular infection, mentioning chemical agents such as afenil, alvonal, urotropine, argoflavine, rivanol, atophan, atophanyl, bismogenol, spirovismol, sodium cacodylate, solarson, and astorin. The biological remedies he had tried were milk, aolan, and caseosan, vaccineurin, artheigon, insulin, and sanocrysin. He had also employed for light treatment the quartz lamp, Solex lamp, the Koppe blue light, and Roentgen rays.

Dr. J. RINGLAND ANDERSON (Victoria) gave an account of red-free ophthalmoscopy in theory and practice. He discussed the history of the discovery of the yellow macula leading up to the work of Professor Vogt and his use of the red-free light in the examination of the macula. He described the appearance of the macula in the enucleated eye, the value of the yellow pigment as a filter, the appearance of the macula with the ophthalmoscope, and the changes in disease. The method of examination with the red-free light was the only one which made visible the yellow macula and its changes in disease, especially in the form of oedema of the nerve fibres and retinal atrophy, the fine retinal plexuses, and the minutest haemorrhages and alterations in vessel walls.

Dr. E. W. HARTY (New Zealand) introduced the subject of ophthalmology and the consulting optician in view of the registration of sight-testing opticians, which was receiving consideration in New Zealand. He quoted W. S. Inman, who stated that while there was a tendency to break away from accepted beliefs about the physical origin of certain diseases, ophthalmology seemed to have lagged behind. Headache was not invariably relieved by corrected errors of low refraction, and other factors seemed to have been insufficiently investigated. Emotional stress was a factor which might be a cause, also heredity, and the stress of modern civilization in school and industry. While great attention was being paid to septic infections, common maladies which were so often the forerunner and in many cases the cause of inflammatory eye conditions and errors in refraction did not appear to receive the attention they merited. He mentioned certain degrees of myopia as inviting careful search for diabetes, glaucoma, and early cataract. The diagnosis of early neurovascular changes was important, and it was these finer points which appeared to constitute the principal objection to granting State recognition to sight-testing opticians. He quoted various authorities in England, America, the Continent, and Australia who were opposed to the recognition of sight-testing opticians.

Dr. ERIC L. MARCHANT (New Zealand) described the operative treatment of lacrymal obstruction. The Washer-Toti operation was the most satisfactory in his experience for lacrymal obstruction. He found it better than West's in cases of congenital obstruction when the sac was small, and he obtained a much wider opening for drainage by this method. He emphasized the necessity for laying open, not only the inner sac wall, but also the entire length of the nasal duct. He tented in the inner sac wall by a probe through the canaliculus, and then transfixed the sac by a straight needle into the nasal cavity, dividing the sac vertically external to the needle. To open up the nasal duct he passed a slightly bent No. 1 knitting pin, and placed a gouge externally to it, ripping out the inner wall. He emphasized the importance of making a large opening and insuring that the opening in the sac coincided with that in the bone.

Dr. CYRIL DIXON and Dr. L. J. C. MITCHELL (Victoria) contributed jointly a report of a series of cases of retinitis pigmentosa occurring in one family. The father, aged 54, and the mother, 56, had six sons and four daughters. Of the sons, one, aged 30, was normal; another, 28 years of age, presented gross deafness, the vision in both eyes being 6/18 with typical retinitis pigmentosa. A third son had died at the age of 21, being blind and deaf; another son, aged 19, was normal, and the sixth son, aged 16½, had right vision 6/9, left vision 6/12. His field was contracted and he suffered from typical end-organ deafness. Of the daughters, three were normal and one, aged 15, had 6/9 vision in both eyes, and definite retinitis pigmentosa with typical gross end-organ lesion. The father had been deaf since the age of 29, but had no eye defects. The mother was normal. The father had had two deaf and dumb cousins, both of whom were dead. The Wassermann test was negative in all cases.

Dr. Z. SCHWARTZ (Victoria) reported a case of squamous-celled carcinoma of the limbus extending over the cornea. A woman, aged 43, attended hospital in February, 1924, the right eye having a vision of 6/5 and the left 6/12. On December 22nd, 1925, when the left eye was examined, there was found a transverse growth across the left cornea, 6 millimetres wide, extending from one limbus to the other. The conjunctiva appeared free; the cornea above and below the growth was transparent. The appearance of the growth was fleshy; it was raised from the cornea with large blood vessels extending across it like an overgrowth of conjunctiva. The eye was congested and there were no enlarged lymph glands. The eye was excised with considerable portion of conjunctiva, and one month later one application of deep x-ray therapy was given. Pathological examination showed the growth to be a squamous-celled carcinoma.

Dr. A. J. HALL (New Zealand) gave a lantern demonstration of fundus diseases and read a note on the pathology of penetrating wounds of the eyeball. He summarized the findings of John Marshall of Glasgow in a number of cases of penetrating wounds, and illustrated them by a series of photographs, stereo-photographs, and microscopic slides. He classified the infection of such wounds as

panophthalmitis, vitreous abscess, plastic irido-cyclitis, and proliferative fibrosis arising from the cut tissue of the wound. In each class a brief account was given of the principal pathological conditions found. Attention was drawn to the probability of an endogenous source of infection in some cases. The pathological changes following retention of metallic bodies were purposely excluded from the paper, which dealt with infection only.

SECTION OF OTOLOGY, RHINOLOGY AND LARYNGOLOGY.

Dr. ROBERT PULLEINE (South Australia) sketched the history of the work during the past fifty years on the anatomy of the vestibular apparatus and the neurophysiology of the internal ear. He described in some detail the relations of the vestibular nerve and the passage of the fibres from the nuclei of the third and sixth nerves to join the fibres of the fourth and sixth nerves to form the vestibulo-ocular tract. He also defined the components of the vestibulo-cerebellar-cerebral and the vestibulo-spinal tracts. On the basis of the anatomical and physiological findings he endeavoured to analyse the slow component of nystagmus. The tests employed by him were the rotatory and the caloric. He concluded that labyrinthine conditions could be clearly distinguished from acoustic tumours, that acoustic tumours gave rise to a definite syndrome, that cerebellar neoplasms were capable of differentiation, and that in toxaemic conditions due to tobacco and dental infections there was an absence of normal vertigo and past pointing. Hysterical forms were rare. He also dealt with spontaneous vertigo in ophthalmic conditions, such as anisometropia when the amblyopia ex anopsia had not evolved, and when heterophoria, especially the vertical variety, could be eliminated by the vestibular tests.

Dr. H. M. JAY (South Australia) read a paper on the diagnostic importance of the vestibular reactions. The vestibular tests appeared to have a very definite value as an aid to diagnosis, provided that too much was not expected of them. Lesions affecting the labyrinth and eighth nerves and the cerebellar cortex should be distinguishable in the great majority of cases. Judging from the fact that the only two proved peduncular lesions in Dr. Jay's series had been correctly diagnosed, it appeared that the tests were of value in these conditions. No proved lesions of the pons or medulla were included in his series, and in consequence no conclusions could be drawn in regard to them. He added that negative findings were of distinct value in eliminating disease of the brain stem.

Dr. T. A. MACGIBBON (New Zealand), in a paper on chronic spheno-ethmoiditis, stated that the importance of this condition lay in the fact that many unexplained diseases had their origin in hidden septic foci. After describing the classification of types and their symptoms, he dealt with the treatment. In the catarrhal type it was sufficient to remove obstructions such as a deviated septum or a portion of the middle turbinal. A long course of instillation of argyrol was useful. Diet, fresh air, non-smoking, and plenty of exercise were indicated. Where polypi were associated with this type, the only rational method of treatment was a complete exenteration of the ethmoid labyrinth and opening up the sphenoid. There were two types of latent spheno-ethmoidal suppuration—the mild and severe. In the mild type with little toxic absorption climatic and local treatment should be tried before operation. Argyrol drops should be instilled at bedtime. In the severe type, where toxaemia was marked, aeration and efficient drainage were to be aimed at. The treatment of manifest empyema was the same as for the severe type of latent suppuration. Closed empyema was treated by causing shrinking of the mucous membrane by cocaine and adrenaline or antipyrin. Flushing with warm Dobell's lotion might cure temporarily. If pain returned the affected cells should be opened up at once; if there was no pain it was best to wait till the acute stage passed off. Spheno-ethmoiditis in children was treated by removal of the remains of the tonsils and adenoids by the radical method, the patients being left to recover by medical and climatic treatment. Dr. MacGibbon then described various operations in detail, including Ballenger's, Mosher's frontal ethmoid, Moure's external ethmoid, Sluder's and Skillern's, and his own operation. He emphasized the importance of preparation for the operation, and careful after-treatment.

Dr. R. PULLEINE (South Australia), in a paper on conservatism in the treatment of middle-ear disease, stressed the necessity of early paracentesis in acute otitis media and referred to the efficacy of counter-irritation over the mastoid. He said that the younger the otologist the more likely he was to consign summarily a chronic discharging ear to surgical intervention. He dealt with hyperkeratosis of the middle ear and attic. After insuring ventilation of the tympanum and the removal of septic foci he described various methods of treatment in detail, including pertubal lavage, high-pressure syringing, zinc ionization, iodine vapour insufflation, antiseptic ear baths, and closure of the Eustachian tube and of the tympanic perforation.

Dr. HAROLD HAYS (New York) read a paper on the management of acute otitis media. He said that the interpretation of symptoms of acute otitis media was most important, and great attention must be paid to them and to the proper examination of the membrana tympani and mastoid process. The chief symptoms were pain and temperature. Of primary importance was the establishment of as free drainage as possible, which meant a wide and extensive opening of the membrana tympani, sometimes even when spontaneous rupture had occurred. If the drum had to be incised, an anaesthetic should invariably be employed, no matter how young the patient, a transient general anaesthetic, such as gas and ethyl chloride, being used. The incision in the drum should be a sweeping one, extending from the upper posterior part forward and downward and then upward to Shrapnell's membrane. In severe cases x-ray photographs taken every few days were useful. The patient was instructed to keep the middle ear clean by frequent douches; sometimes frequent mopping out was advised or suction was used. Several specific treatments used by the physician were of value; these included cleansing and abortive treatment, zinc ionization, acriviolet solutions, mercurochrome, local vaccine therapy, ultra-violet rays, and the restoration of hearing. In a certain number of cases the discharge persisted and the general physical condition remained below par. In these cases a mastoid operation was a conservative procedure.

Dr. ERIC GUTTERIDGE (Victoria) read a paper on paranasal sinusitis in children. He discussed the embryology and anatomy of the individual sinuses before he approached the clinical aspect of sinusitis. This condition was frequent in children; it had protean manifestations and attacked the respiratory tract in the majority of the patients. The vast proportion of respiratory diseases owed their origin and persistence to sinusitis and could be remedied by treatment of the nose and throat. The effects of enlarged and infected tonsils and adenoids were largely due to the accompanying sinusitis, and removal of these lymphatic infections usually resulted in cure. In his series 85 per cent. of the patients had been dealt with in this way. Dr. Gutteridge was particularly concerned with the 20 per cent. in whom tonsillectomy had failed to cure the sinusitis; after some months it was found that 21 per cent. were much improved, 30 per cent. were improved, 17 per cent. were in the same state, and 32 per cent. were not seen again. This meant that of those of whom a report had subsequently been received, 80 per cent. were improved or relieved. Whether the children had been permanently cured or their symptoms temporarily relieved, it was impossible to determine. The gain to their health and the relief to their lungs and developing nasopharynx were of inestimable value. A similar treatment would probably be successful on a second occasion. There remained a residuum of patients who would require further treatment. The Caldwell-Luc operation had been performed on 14 per cent. of the children, and the mucosa had been found to be polypoid in 7 per cent. No complications, such as meningitis, frontal osteo-myelitis, or orbital abscess, as noticed by Skillern and others, had been seen in his clinic.

Dr. GEORGE PINESS (Los Angeles) read a paper on allergy of the respiratory tract. He sketched the history of allergic disease and then proceeded to the etiological classification of asthma and hay fever; food allergy was the most common cause of perennial asthma and hay fever,

while pollen allergy might be seasonal (spring or fall) or perennial. Animal dander, orris root, and pyrethrum were frequent causes of allergy. For diagnosis he relied on the family history, the clinical history, the physical examination, *x*-ray examination, laboratory research, and the skin tests. He described the scratch method and the intradermal method of performing the skin tests, and stated that the first essential was the use of test proteins known to be active; the commercial food proteins had proved unreliable in many cases. The average patient was tested with 350 proteins. He then dealt fully with specific treatment based on the results of the skin tests.

SECTION OF NAVAL AND MILITARY MEDICINE AND SURGERY.

This Section joined in two combined meetings, and one day was devoted to a staff ride, which was discussed on a subsequent morning. Forty-five army medical officers took part in this medical tactical exercise and various problems were dealt with arising out of a supposed attack by foreign troops.

Colonel F. A. MAGUIRE, D.S.O., Deputy Director of Medical Services, Australian Military Forces, read a paper on medical work in the field, with special reference to the battle of Messines. He summarized the main requirements for medical field work as follows: (1) rapid evacuation, (2) provision of warmth, (3) ample supply of hot fluids, (4) gentle handling. These necessitated good staff work, ample supplies, and the thorough training of personnel. He discussed the battle of Messines, *in so far as it affected* Australian and New Zealand troops, to show how it had provided every opportunity for the practice of the principles enunciated. It was a "set piece"; the plans were laid for it months ahead, and preparations were developed on an elaborate scale. Colonel Maguire described in detail the arrangements made for this operation, and gave figures of the number of casualties dealt with. He considered that the staff work throughout was excellent, and that the whole operation was a model of what medical organization should be.

Colonel R. TRACEY INGLIS, C.B.E., V.D., Director of Medical Services, New Zealand Military Forces, gave a lucid explanation, illustrated by diagrams, of medical organization in war.

Lieutenant Commander W. E. J. PARADICE, Royal Australian Navy, described cases among naval patients of interest from a bacteriological point of view, and gave particulars of Vincent's angina and allied conditions met with at the naval depot at Garden Island, New South Wales. He classified Vincent's angina affecting the tonsils into three groups: (1) In the pure infection the ulcer was almost white and very hard and friable; there was only slight constitutional disturbance. Spirochaetes and fusiform bacilli were present in pure culture. (2) In a mixed infection, with Vincent's organisms predominating, the ulcer was whitish, hard, and friable, and there was marked constitutional disturbance. Spirochaetes and fusiform bacilli were present in large numbers accompanied by various other organisms. (3) In a mixed infection, when Vincent's organisms were only present in small numbers, the ulcer was yellowish and soft, and exuded pus. The constitutional disturbance was variable, and there were a few spirochaetes and fusiform bacilli present among large numbers of other organisms. He had found that the best results were obtained by the use of liquor arsenicalis and 1 in 5,000 perchloride of mercury, alternately, applied by means of a small amount of wool on a wooden applicator or probe. Other conditions caused by spirochaetes were gingivitis and balanitis. Lieutenant Commander Paradice also furnished particulars of two cases of cystitis yielding a coccus, apparently *Staphylococcus albus* of aberrant form; both yielded to treatment with potassium citrate. Two further cases of cystitis yielding coliform bacilli were mentioned; in both these pain had been present in the right iliac fossa, and, later, urinary symptoms arose, thus appearing to support the contention that this form of cystitis was secondary to an inflammatory condition of the alimentary canal, the appendix in particular.

Lieut.-Colonel A. D. CARBERY, C.B.E., V.D. (New Zealand), dealt with some medical aspects of recruiting for war, and analysed the attestation papers of New Zealand recruits in the great war. He considered that the lessons to be learnt from this analysis were the following. Men below the prescribed standards in weight and chest measurement should be classified B3 if otherwise acceptable. The acceptance of C1 men for special training was, he considered, of doubtful value, and they should not be considered fit for service overseas unless they showed a considerable improvement in weight under graduated training. The minimal requirements of physical measurement laid down in the R.A.M.C. regulations for 1923 should not apply to New Zealand soldiers, as there was evidence that their average physique was better than that of British recruits. Attestation forms required remodelling, and the pulse and respiratory rate in relation to exercise should be noted. The nervous, glandular, and genito-urinary systems required a special column in which their condition should be recorded. The ears should be examined in all cases. Medical officers selected for the important work of recruiting for mobilization should be specially trained in peace time. No form of physical inspection of recruits could hope to eliminate all defectives or detect disease tendencies, but, as evidence of the improvement, he instanced the recent reports of the Surgeon-General, which showed that the rejection of recruits after a few months' training had been much reduced by improved methods of examination and greater acumen in selection.

Major W. AITKEN, medical superintendent at Cashmere Hills Military Sanatorium, discussed the after-histories of patients treated at the Military Sanatorium during the years 1919-24. An attempt had been made to determine the post-sanatorium experience of 421 discharged patients and the benefit derived from the treatment. The patients were dealt with under three groups as follows: (1) Cases with slight constitutional disturbances and physical signs of tuberculosis of limited extent—for example, in one lobe only. In the case of an apical lesion in the upper lobe the signs should not extend below the second rib in front, and in the case of lesions other than apical the signs should be limited to an area of equal extent. If present in more than one lobe the signs must be limited to the apices of the upper lobes, and not extend below the clavicle and spine of the scapula. (2) All cases which could not be placed in groups (1) and (3), and with, at most, the whole of one lobe affected. (3) Cases with profound systemic disturbance or constitutional deterioration; with marked impairment of function or with an extent of disease greater than the whole of one lobe; and with grave complications, whether tuberculous or not. With reference to (1), the arrest of the disease secured under treatment was maintained in 83.6 per cent. The percentage at work—72.8—also showed that the sanatorium had played a useful part in rehabilitating tuberculous ex-soldiers for civilian life. In group (2) the percentage with the arrest of the disease maintained was 53.6, and the percentage at work 43.4. It was claimed from the results of this group of cases in the middle stages of a grave disease, such as pulmonary tuberculosis, that the treatment as carried out in the sanatorium had been amply justified. In group (3) the inquiry showed that the inevitable results of late diagnosis were not offset by sanatorium treatment; 75 per cent. of the patients in this group died within one to six years after discharge. In determining the usefulness of the work of the institution, the value to the community of the segregation of highly infective cases had to be indicated, also the nursing care and alleviation of the suffering of hopeless cases, for the provision of which the Dominion Government was responsible.

Squadron Leader A. P. Lawrence, Director of Air Medical Services in the Royal Australian Air Force, read a paper on measures for the protection of the civil population against gas attacks from the air. After dealing with the possibility of attacks with poison gas from the air and the probable nature of the gas used he concluded that the measures for protecting the civil population should comprise: The dissemination of knowledge concerning the effects

of a gas attack and of the precautionary measures to be adopted; the provision of an air raid alarm and of shelter in which inhabitants could obtain protection during and subsequent to an attack; the organization of a service for clearing an area of gas and for dealing with casualities and persons affected; and the military control of this service.

Major KENNETH F. GORDON, New Zealand Medical Corps, read a paper entitled "Work at an advanced dressing station near Crèvecoeur in 1918," and gave an excellent description of his experiences during the operations in the early part of October, 1918.

SPECIAL EVENING DISCUSSION.

THE RELATION OF THE MEDICAL PRACTITIONER TO THE STATE AND THE HOSPITALS.

A special evening meeting was arranged to discuss the relation between medical practitioners, the State, and the hospitals.

Dr. J. NEWMAN MORRIS (Victoria), the opening speaker, took as his subject the part played by the medical practitioner in the prevention of disease. He maintained that in the first place the essential unity of the preventive and curative activities of the medical profession must be realized. Medical practitioners had the first, and consequently the best, opportunity of taking or advising steps for prevention. The importance of prevention was not sufficiently emphasized in the medical curriculum, hence it was essential to stimulate the interest of the practitioner in preventive work, and to educate public opinion. No opportunity should be lost of publishing the facts of disease prevention, giving advice, and teaching. This could be effected by service on committees, such as those of baby welfare centres, in municipal bodies, and in Parliament, or by giving lectures on prevention under the auspices of the British Medical Association. Systematic examination of the apparently healthy was to be encouraged, as, for example, by a yearly overhaul to detect disease in its earliest stage. In the prevention of disease certain legal obligations had already been imposed on the medical profession. The Royal Commissioners had suggested further duties, and it was impossible to forecast all the requirements which might legally be imposed. Conscientious practitioners would be aided, while the dilatory and slack would be revealed. Dr. Morris described various ways in which practitioners could aid preventive medicine, and also ways in which the State could, scientifically and financially, help practitioners—such, for instance, as the provision of accessible diagnostic laboratories and granting increased fees for statutory duties.

Dr. M. H. WATT (New Zealand) said that the State took a very active interest in the prevention and treatment of disease, and was watched with suspicion by the private practitioner, whose orbit lay between the consulting room, the patient's home, and the hospital. In all three places he could be an active force in preventive medicine, and the activities of the State in each place would be in inverse proportion to his own. Dr. Watt advocated periodic overhaul of the general public, dealing with the whole family as well as the case in infectious diseases, and the provision of paying wards for private patients in hospitals, as being measures worthy of the medical practitioner's immediate attention. The practitioner was advised to make free use of the hospital when confronted with difficult cases requiring elaborate equipment for diagnosis, and also as meeting places for mutual clinical instruction and education. The ideal was that the practitioner should function as a medical officer of health, interested as much in the prevention of disease as in the cure and care of the patient.

Mr. R. J. LOVE (Victoria) remarked that at present the indigent sick obtained ample hospital accommodation and facilities for treatment, where the best of medical attention was given freely and ungrudgingly, but the community was drifting towards general dependence on free medical treatment. There was a constant growth, both actually and proportionately, in the numbers of people who took advantage of free public hospital treatment, and who were not wholly to blame, since it was natural for people to go where the best service was obtained at the least cost. To counteract this tendency the facilities for treatment should be widened, and grades of hospitals established corresponding, as regards cost, with the respective grades of society, working always towards the community hospital system. Mr. Love viewed the community as consisting of four classes, and described hospitals to suit each—namely, private, intermediate, third class, and public or free class. He explained how both hospitals and medical practitioners could help in the evolution of such a scheme, and in furtherance of preventive medicine, paying special attention to the departments for periodic medical examination, tuberculosis, and social service. Hospitals should be standardized to meet all preventive as well as curative requirements; all members of the profession should take full advantage of the facilities provided, and co-operate in a vigorous policy of prevention.

Dr. T. MCKIBBIN (New Zealand) agreed that medical practitioners did prevent disease, but considered that it should be their main objective both in town and country. The demand was arising for public health nurses, and for an extension of public hospital activities to include disease prevention; the co-operation of medical practitioners was desirable, but depended on their own attitude. Dr. McKibbin would like to see practitioners definitely allied with the Department of Health and the local governing authorities for the purpose of disease prevention, and believed that the only sound and fair way of reaching that objective was by national insurance, compulsory for all persons in receipt of low incomes, in order to prevent disease. This would improve the lot of the majority of the medical practitioners, and definitely benefit the public health.

England and Wales.

POST-GRADUATE INSTRUCTION AT THE ROYAL NORTHERN HOSPITAL.

THROUGHOUT the year, with the exception of August and September, post-graduate courses are held at the Royal Northern Hospital on Tuesday afternoons at 3.15. The lecture is given by a member of the hospital staff, and some subject is treated in such a way that the practical implications are brought out. No charge is made for attendance, and tea is provided at the conclusion of each lecture. This arrangement has proved to be very popular, the time and the nature of the topics attracting many general practitioners. An "intensive course," which was much appreciated, was held in February; it extended over one week, lectures and demonstrations being given each afternoon. The remainder of the time available in the morning and afternoon was devoted to teaching in the wards and other departments of the hospital. The next "intensive course" will be held from May 23rd to 27th, when special lectures will be given on the diagnosis of pulmonary disease, rectal diseases, the uses of radium in gynaecology, common skin ailments, anaesthesia, modern methods in relation to digestive disorders, visceroptosis, and the diagnosis of diseases of the heart and chest. During the first fortnight in March a course was held for the M.R.C.P. and other higher examinations. A similar course will be held in the second half of June. It will last between two and three weeks and comprise recent advances in medicine, medical anatomy, and points in biochemistry, bacteriology, and general pathology. Further particulars may be obtained from Dr. E. G. B. Calvert, the dean of the Royal Northern Hospital.

INSTITUTIONAL PROVISION FOR RHEUMATIC CHILDREN.

In July last the subcommittee set up by the British Medical Association to inquire into the subject of cardiac disease in children reported[1] that it was clear that the need of rheumatic children for prolonged care was imperfectly realized in the country as a whole. The subcommittee urged the necessity for each large city to be provided with the means for institutional treatment of rheumatic children in the course of which the children

[1] SUPPLEMENT, July 3rd, 1926, p. 1.

could receive controlled rest with plenty of sunlight and fresh air for periods of months. We are glad to learn that the Metropolitan Asylums Board has now made a decided move in this direction. At its meeting on April 9th the Board resolved to provide 350 beds for the treatment of London children suffering from rheumatic diseases, and for this purpose to extend Queen Mary's Hospital for Children at Carshalton. This institution, which is twelve miles from the city, has at present 900 beds for acute tuberculous cases and various non-tuberculous cases requiring active or operative treatment. The new accommodation is to be for children of both sexes, under 16 years of age, who are suffering from subacute rheumatism, the later stages of acute rheumatism, rheumatic chorea, or rheumatic carditis, including recurrent attacks. As the enlargement of the hospital will necessarily take some time, the Board has also decided that 56 beds at another of its institutions, High Wood Hospital for Children, at Brentwood, in Essex, shall be temporarily allocated to meet immediate and urgent requirements. At Carshalton there is already a special unit of 60 beds, provided in the early part of 1926 for the accommodation of children suffering from rheumatic fever, acute endocarditis, or chorea. The establishment of this unit, which followed upon a report by Dr. W. T. Gordon Pugh, the chief medical officer of the children's and surgical tuberculosis services to the Board, was intended primarily for research purposes, and it was clearly understood by all concerned that this was not to be considered as an attempt to deal with the problem of providing accommodation on a large scale for children absent from school through rheumatic illness, except in so far as successful research on this small number of cases, which were to be admitted as early as possible and in the most acute stage of the disease, might tend to reduce the number of such cases. More recently the Board was informed that the Ministry of Health is satisfied that there is urgent need for the provision of additional hospital accommodation for London children suffering from rheumatism, and that if the London County Council requested the Board to provide the necessary accommodation, and the Board agreed to do so, the Ministry would approve. The Board considered the two alternatives of building a new institution specially for the purpose or of extending St. Mary's Hospital for Children. The Board has available a site of 156 acres at Copthorne, near East Grinstead, purchased with a view to a sanatorium for tuberculosis on a scheme which fell through as a result of the war, but after consideration it decided that, owing to the non-availability at Copthorne of essential services, it would be more economical to extend the Carshalton institution, where the present chief officers would be available for supervisory purposes, and where questions of access and housing of staff would present no particular difficulty. The Board had before it a report presented to the London County Council by the county medical officer (Dr. F. N. Kay Menzies), in which it was computed that in the London area not fewer than 10,000 children have suffered or are suffering from rheumatic symptoms. The great majority of these are not in need of any special treatment other than that which they are already receiving, but they require careful watching. About 1,000 of these children, whose hearts have been seriously and permanently injured, attend special (physically defective) schools, and there are from 600 to 700 others who are absent from school for long periods on account of rheumatism. These last represent 25 per cent. of the chronic invalidity among school children, and include all, or almost all, the children for whom the special arrangements now proposed are necessary. In 1925 the number of children reported chronically out of school on account of this disability was 614, of whom 144 were said to be suffering from rheumatism, 224 from heart disease, and 246 from chorea. The incidence of rheumatism appears to be greater generally among girls (65 per cent.), and the high proportion of cases of chorea to the total illustrates the very special incidence on the nervous system in school children.

BRITISH EMPIRE CANCER CAMPAIGN.

Viscount Cave presided over the quarterly meeting of the Grand Council of the British Empire Cancer Campaign on April 12th. An application by the National Cancer Campaign of Ireland for affiliation to the Campaign was approved. Both Ulster and the Irish Free State are represented in this Irish organization, its membership, including representatives of the Royal Colleges of Physicians and Surgeons in Ireland, Queen's University, Belfast; Trinity College, Dublin; the Royal Academy of Medicine in Ireland; the Royal City of Dublin Hospital; the Royal Dublin Society; and the British Red Cross. Grants of £298 and £900 respectively were made for apparatus and for the upkeep for one year of the radiological cancer research department of the Middlesex Hospital, and a further grant of £3,000 to the general cancer research department at this hospital was approved. The grant of £100 to Mr. E. Nevill Wilmer, of Manchester University, was renewed for one year to enable him to continue work on tissue culture, and a further grant of £300 was made to Professor Charles Walker of Liverpool. The resignation of Lieut.-General Sir John Goodwin was received, and the council tendered him congratulations and good wishes on his appointment as Governor of Queensland. Sir Archibald Bodkin was elected a member of the grand council and executive committee. Sir Richard Garton, chairman of the finance committee, drew attention to the necessity for a sustained effort to obtain adequate annual funds to subsidize the important work in progress in the various cancer research laboratories. It was announced that arrangements for a combined Lancashire and Cheshire appeal were being considered.

Scotland.

SCOTTISH UNIVERSITIES' PARLIAMENTARY REPRESENTATION.

THE nominations of the two candidates for the vacancy in the Scottish Universities' parliamentary representation, as announced in the BRITISH MEDICAL JOURNAL of April 9th and 16th, were duly handed in at a meeting on April 8th, at which Principal Sir J. Alfred Ewing presided as returning officer. He announced that the poll would be held on Tuesday, April 26th, and on the three following days, and that the result would be declared on April 30th. Members of the Scottish Universities' constituency are reminded that voting is carried out by post and that they should immediately fill up the voting paper when received and post it to the returning officer of their respective university.

INFECTIOUS DISEASES AT DAIRIES.

A circular dated April 13th, 1927, has been issued by the Scottish Board of Health, drawing the attention of local authorities to the provisions of the Milk and Dairies (Scotland) Act, 1914, which deal with infectious disease. The object of the circular is to point out that, in the prevention of tuberculosis and infectious disease due to infected milk, dairymen and their employees can give great assistance and are bound by law to do so. It is believed that if the provisions of this Act were carefully applied by the producers of milk and their employees, milk-borne tuberculosis and such infectious diseases as diarrhoea, dysentery, enteric fever, diphtheria, and scarlet fever would be almost entirely prevented. The circular complains that when a milk supply is suspected of causing disease the attitude of the producer of milk and his employees is too often one of indifference or of actual obstruction, and it alleges that during 1926 several outbreaks of infectious disease were spread by milkers who, themselves infected, continued to milk cows. In one instance about 150 persons became affected by dysentery through a milker breaking the law by continuing to work while suffering from this disease, while in an outbreak of scarlet fever over 150 cases were traced to a milkmaid who continued to milk cows while suffering from a mild attack of the disease. In both essential facts had been withheld from the medical officer of health. The circular advises that certain provisions should be strictly enforced by the local authorities in the public interests. It is pointed out that a dairyman is required to report to the medical officer of health symptoms of infectious disease occurring in any person resident or employed at the dairy or any person residing in the same house as an employee of the dairy.

A dairyman is liable to a penalty if he allows any person to milk cows or to handle milk vessels while suffering from diarrhoea, sore throat, any suppurating sore, or any infectious disease, or if he allows any person to milk cows or handle milk vessels if that person has recently been in contact with a case of infectious disease. Notification is incumbent also on the dairyman if he has in his dairy any cow suffering from a sore on the teats, accompanied by suppuration or bleeding, or from any disease liable to contaminate milk, or any cow giving tuberculous milk. Attention is also drawn to a by-law to the effect that the hands and forearms of milkers and of any persons engaged in handling milk or milk vessels are to be thoroughly washed and to be dried on a clean towel before work is begun. Medical officers of health are advised to take the family doctor along with them in cases where the physical examination of any patient is necessary, and where cases of disease have occurred and there is reason to believe that the origin of the disease is a milk supply. Medical officers of health should also take particular care to control the movements of those who are in attendance on a case of infectious disease at a dairy and to investigate the houses of persons employed in the dairy and examine inmates of such households. Where infectious disease occurs in families supplied with milk by one dairy and where the medical officer of health is reasonably satisfied that the infection is carried by that milk supply, even although after a visit to the dairy the actual source of the outbreak is doubtful, the medical officer of health should make an interim order, but the local authority can make an immediate order stopping the milk supply. A possible alternative for the farmer as an emergency measure is a complete change of milkers and all those who handle milk, together with thorough washing of the cows' udders and disinfection of all utensils and apparatus concerned. The Board of Health suggests that in any case where information has been withheld wilfully the dairyman or the employee or both shall be proceeded against. The local authority is liable to pay to a dairyman full compensation for any loss arising out of the order stopping the milk supply if the damage has not arisen by reason of the dairyman's default, but it is pointed out that this should not deter the local authority from making such an order when stoppage of the milk supply is recommended by the medical officer of health, because inaction of this kind may be false economy.

GLASGOW SLUM CLEARANCE.

Details of an extensive slum clearance scheme were given at a meeting of Glasgow Corporation on April 12th. The estimated cost of the scheme is about £480,000, the annual deficit being calculated at about £17,000, of which the Government subsidy amounts to 50 per cent.; the remaining 50 per cent. represents an addition of one-fifth of a penny per pound to the rates. The number of houses involved is 1,019, and it is intended to house the dispossessed tenants in various new areas where the corporation is at present erecting houses. The largest area involved in the scheme is in the Bridgeton district.

Ireland.

MEDICAL REGISTRATION IN THE FREE STATE.

IT is stated that on the reassembling of the Dail after the Easter recess a bill will be introduced settling permanently the question of medical registration. It is believed the bill will provide that the General Medical Council as at present constituted will control medical education in Ireland substantially on the lines of the present system, and that newly qualified medical men in the Free State will continue as hitherto to occupy the same position in the *Medical Register*. For disciplinary and purely local affairs in the Free State it is believed that an agreement has been reached between the British and Free State Governments for the establishment of a Medical Council and Register in the Saorstat. All medical practitioners who desire to practise in the Free State must have their names in the Medical Register of the Free State. The bill will also provide for reciprocity between Great Britain and the Dominions and the Irish Free State.

SCHOOL MEDICAL SERVICE IN BELFAST.

A scheme of school medical service has been adopted by the Belfast Corporation on the advice of the Education Committee. It is estimated to cost over £9,000 a year. The city will be divided into three districts, each with a clinic and staff. In addition to the medical officer of health, who will supervise the scheme, the staff consists of a chief medical officer, at a salary of £750 a year, and three doctors as assistants, one of them a woman, who receive £500 each, and a part-time woman doctor at a salary of £250. The part-time service of a specialist (twelve hours a week) has been retained for the central clinic at £500 a year. In addition, there is an eye specialist and an aurist for the branch clinics (part-time) at £210 a year each, and four part-time dentists at £200 a year each. There are fifteen nurses, with salaries ranging from £109 to £131 each, and this number will be increased when the new central clinic and operation department is fully organized. There are, in addition, three clerks, messengers, and caretakers for the clinics, and several women, described in the scheme as "head-cleaning women," whose duty it is to deal with specially bad verminous cases. The staff is divided over the three clinics. In the forenoons they carry out inspections in the schools, and in the afternoons are in the clinics to deal with any cases requiring treatment. There are 65,000 children attending the elementary schools in the city. As it would not be possible to examine all these children every year with the present staff they are arranged in age groups, and it is proposed to examine them at 6 years of age (entrance group), at 8 years, and at 12 years (leaving group). In this way, whether there is anything wrong with the children or not, each will be completely examined three times during the course of their elementary school career. Before the periodical visits of the doctor the teachers and pupils are notified, and any child in the school not included in the particular age group to be examined is examined specially, if, in the opinion of the principal or parents, this is necessary. Children found defective at a previous examination are re-examined to ascertain whether treatment has been obtained, and with what result. A feature of the school medical inspection is the interest taken in it by the parents, a great many of whom come to the schools on inspection days, and are present in the private room with the doctors and nurse when their children are being examined. Many defects not previously noticed are discovered at these inspections, especially in regard to eyes, ears, and throats, and the parents always seem anxious to listen to the opinion of the doctors and have their advice carried out. Children requiring more detailed examination and treatment are referred to the clinics. At first there was some protest among the parents at the inspections for cleanliness, especially when children were sent home with instructions to have their heads washed with chemicals prescribed by the doctors and nurses, but this has now disappeared, and all the parents, realizing that it is in the best interest of the children, endeavour to conform to the instructions. There has been a marked improvement in the cleanliness of the children, and also a steady improvement in their health. All the children attending the schools are examined periodically by the school nurses in respect of cleanliness.

Correspondence.

MIGRAINE.

SIR,—As the subject of migraine is receiving much attention in your pages a note on the following case may be of interest.

Some years ago I had under my care a severe case of migraine. The patient was a lady in early middle life. She was of somewhat fragile physique and artistic in her tastes and aptitudes. Her husband was head of a great public school which gave nine or ten weeks' holiday in summer. The patient and her husband were both fond of travel and went abroad nearly every summer, often to South Europe. She never had an attack while travelling.

This case gives some support to the usual view that

migraine is essentially a neurosis. Change of climate and environment, relief from domestic cares, the stimulation of new scenes, and fresh interests served to prevent the attacks.—I am, etc.,

Belfast, April 12th. J. A. LINDSAY, M.D., F.R.C.P.

VENESECTION.

SIR,—In your issue of April 16th (p. 721) there is reported a discussion on the subject of venesection which raises some very important points. I am, however, struck by the absence of any statement regarding experimental blood-letting, except that by Mr. French to the effect that physiologists consider the procedure useless. This statement owes its origin to faulty experimentation.

The facts are that, although venesection only reduces arterial pressure for a short period, the arterial recovery is largely due to a compensatory action on the part of the vasomotor system. Evidence that pressor fibres pass up the vagus has been put forward by me, and has been confirmed by Anrep and Starling. As a result of the contraction of the peripheral vessels to keep up the arterial pressure, there is brought about a profound fall of venous pressure which is relatively lasting and which must be of enormous value in relieving the right side of the heart.

In my recent volume *Clinical Physiology in Relation to Modern Diagnosis and Treatment* I have stated the circumstances in which venesection is indicated on physiological grounds, but when the fall of venous pressure is appreciated it will readily be seen how many of the conditions referred to by various speakers in the discussions will be relieved.—I am, etc.,

R. J. S. MCDOWALL, D.Sc., F.R.C.P.Ed.
(Professor of Physiology).

King's College, London, April 16th.

PATENTED RESEARCH.

SIR,—There has recently come into my hands a letter from a German firm—the *Edelweiss Milchwerk*—*advertising* a dried milk which has been irradiated with ultra-violet light to increase its antirachitic potency. This milk they name "Ultractina," and they state that "a letters patent has been applied for in all States." Whether or not a patent has been granted them in this country I do not know, but I understand this is not the first patent applied for in this connexion.

H. Steenbock and A. Black (*Journ. Biol. Chem.*, 1924, lxi, p. 405) and A. F. Hess (*Science*, 1924, lx, p. 269) were the first to demonstrate that exposure to ultra-violet light will render certain foodstuffs powerfully antirachitic. Since that time there has been a great mass of work carried out on this subject, a large share of it by investigators in America and Great Britain, leading up to the discovery by Rosenheim and Webster that ergosterol by irradiation can be rendered a more powerful antirachitic than any other substance known (BRITISH MEDICAL JOURNAL, March 12th, 1927, p. 485). Can a firm having *no connexion* with the original work on irradiated foods patent irradiated dried milk? If so, there appears no logical reason why irradiated ergosterol should not similarly be patented for commercial exploitation by such a firm.

It has been an honourable tradition among members of the medical profession, as well as many other scientific workers, that all advances in knowledge gained by them should be freely available to all—and this in spite of the straitened circumstances of so many research workers. Surely if the discoverers are to forgo all pecuniary reward it is all the more incumbent on the State to prevent the patenting of their results by firms whose interest therein is commercial. If this is not done is it not probable that many investigators will follow the example set by the Drs. Dick?

I understand that the granting of a patent can be opposed by an *interested party on the plea of previous* publication, but is it likely that all those interested will learn in time of the application for a patent? And, moreover, is it not adding injury to insult to place the onus of opposing the patent in the public interest on the shoulders of the original discoverers?—I am, etc.,

London, W.1, April 3rd. H. M. M. MACKAY.

SOME POINTS ARISING OUT OF RECENT VACCINATIONS.

SIR,—Having recently, as public vaccinator to the Ormskirk Union, completed a series of nearly 3,300 vaccinations during the late outbreak of small-pox in Southport, I think a few observations would be of interest.

The area of skin chosen for vaccination was cleansed with spirit and the lymph expressed on to the lancet, previously sterilized by being passed through the flame of a spirit lamp. Four minute scarifications were made in the epidermis, no blood being drawn, the distance apart varying with the area available for vaccination. A circular pad of boric lint completed the operation. The patient was advised to keep the bowels freely open with saline aperients; he was visited again at the end of a week, when an antiseptic and sedative dusting powder was applied to the pocks and a fresh boric lint dressing adjusted.

These vaccinations were carried out in January and February, a time of year when the health of the populace is depressed, yet in spite of this it was only necessary for me to revisit five cases. The first was a girl who stood up in a shop all day and who insisted on being vaccinated on the leg. The second was a woman, aged 45, who had a reaction for a couple of days, simulating influenza. The third was a boy of 12, who had sickness and slightly raised temperature for a couple of days. The fourth and fifth were mental, as the vaccinations had not even taken. There were one or two cases of malaise, which a day in bed soon corrected and the parents thought too mild to require my attention.

There were, of course, a few cases of work and school dodgers, in some of whom vaccinations had not even taken. Four cases came to the surgery as the pocks were delayed in healing, the protective scabs having been knocked off, which was easily understood as they all used their arms vigorously, being cleaners, etc.

In several instances, in homes from which a case of small-pox had been removed, the remainder of the inmates proved insusceptible to vaccination. In one house seven were insusceptible, whilst across the road, in a house where no case of small-pox had occurred, all the scarifications formed pocks. In one house where a case of small-pox had occurred I vaccinated three persons and omitted a fourth; none of the vaccinated showed any reaction, but the unvaccinated at the end of a week developed small-pox and had to be removed.

It is advisable for all vaccinated persons to keep their bowels well open with saline purgatives, as no other substitute seems to eliminate toxins so thoroughly. This was peculiarly noticeable at the school clinic, when I was able with unerring accuracy to pick out those who had disregarded the advice given—as regards the regularity of the bowels and of taking a saline purgative—owing to a slightly greater inflammation surrounding the pocks. A primary vaccination in an adult gave a more severe reaction than in a young person. Spare and thin people stood vaccination better than the plump and full-blooded; in fact, a well filled arm will only stand one or two scarifications.

For ladies, to whom any visible scarring is abhorrent, the method advocated by H. Goldberger gives excellent results. In this the vaccination is performed on the inner and back side of the arm. This, however, is only applicable to patients who will carefully keep the intervening pad between the arm and the chest so as not to allow of any secondary vaccination.—I am, etc.,

Southport, April 12th. G. GORDON RIGBY.

CERTIFICATION OF THE INSANE.

SIR,—I would supplement the letter of Dr. Daunt (BRITISH MEDICAL JOURNAL, April 16th, p. 745) with further quotations from the same source—namely, the *Times* report of April 1st of de Freville *v.* Dill, before Mr. Justice Avory and a special jury.

Mr. Singleton: If a doctor finds a patient raving, if in his presence she assaults one or more persons, and threatens to kill one or more persons, is it not his duty to send for the police and the relieving officer?

Dr. Hyslop: No; he should send for nursing aid . . .

Dr. Risien Russell said that facts communicated by others should not be used without confronting the patient with the person

making the statement. In cross-examination, Dr. Russell said that "even if Dr. Dill saw and heard her threaten to kill her husband, he ought to have confronted her with her husband."

I would invite the above experts to state whether or no they are correctly reported. I would also invite other experts to comment on the opinions herein set forth. —I am, etc.,

Chichester, April 16th. G. C. GARRATT.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

IN the House of Lords, on April 12th, the Royal Assent was given to the Sale of Food and Drugs Act and other Acts. The House rose till April 28th. The House of Commons stands adjourned till April 26th.

Shops Acts.

The Departmental Committee which is inquiring into the Shops Acts of 1920 and 1921 heard further evidence on April 13th, at the Home Office. Evidence in favour of the Act of 1920 being made permanent was given by witnesses from the Drapers' Chamber of Trade. Mr. Austin Fudge, a draper of Earlsfield, S.W., said that the early closing hours, in view of the Summer Time Act, had proved a blessing to thousands of young women shop assistants. Sir Herbert Ormond, chairman-elect of the Executive Council of the Drapers' Chamber of Trade, expressed the opinion that all shops, with very few exceptions, such as those for the sale of medicine and surgical instruments, ought to be closed at 8 o'clock. Mr. J. R. Leslie, general secretary of the National Amalgamated Union of Shop Assistants, Warehousemen, and Clerks, said that it [illegible] union anything which would increase the [illegible]gaged in shops would lower the standard [illegible]op workers and their children. The witn [illegible] dealing with closing legislation in the Dominions and in foreign countries. This showed that in New South Wales pharmacists and chemists were brought within the regulations, and closed at 7.30 on ordinary nights, with one day at 1 o'clock and one night at 9 o'clock. In Denmark during prohibited hours only certain scheduled articles could be sold from chemists' shops. The committee adjourned until April 27th.

Notes in Brief.

Sir Austen Chamberlain is not aware that the Soviet Russian Government has indicated its willingness to renounce preparation of poison gases provided other countries do likewise.

In 1926, excluding lunatics in asylums, 1,283,801 persons were receiving Poor Law relief in England, and 222,719 in Wales and Monmouth.

Mr. Chamberlain states that in England and Wales, in 1926, there was spent on additional benefits under the National Health Insurance Act £1,146,700 for dental benefit, £155,900 for ophthalmic treatment, £228,800 for treatment in hospitals, £43,400 for treatment in convalescent homes, and £33,900 for surgical appliances, besides smaller sums for other purposes.

Alluding, on April 14th, to a remark by the Hammersmith coroner that legislation should be introduced to prohibit the sale of poison such as crude carbolic acid by hawkers in the streets, Sir W. Joynson-Hicks said the retail sale of crude carbolic was already restricted under the Poisons and Pharmacy Act, 1908.

Obituary.

A. STANFORD MORTON, M.B., C.M., F.R.C.S.,

Consulting Surgeon, Royal London Ophthalmic Hospital.

WE regret to announce the death of Mr. Andrew Stanford Morton, who was for many years a well known London ophthalmic surgeon and an outstanding figure among his colleagues throughout the country. He retired from practice in 1920, and went to reside in Clifton, where he had relatives. He died on April 11th at the ripe age of 79 years. He graduated M.B., C.M.Ed. in 1874, and then went to University College, London. He became M.R.C.S. in that year and F.R.C.S. in 1888. He early turned his attention to ophthalmology, and became surgeon to the Royal Eye Hospital in Southwark; later he joined the staff of Moorfields, where he worked for many years, ultimately becoming one of its senior consulting surgeons; he also held the office of ophthalmic surgeon to the Great Northern Hospital. Morton—for no one ever spoke of him by any other designation—was best known for his ophthalmoscope, which it is safe to say that nearly everyone has used or uses. The basis of his well known instrument was the invention of Couper. The peculiarly ingenious magazine of lenses, set freely in their case, but capable of being moved in turn beneath the sight-hole by the geared wheel, was the fruit of Couper's desire to provide an ophthalmoscope that would be a perfect and complete instrument for the estimation of refraction. That was before the days of retinoscopy. He attained his object; his instrument was a brilliant success, but it was so large and costly that few could or would possess it. Morton cut down the magazine to modest proportions, added an adapter that made up for the loss of many lenses, and, later, a double nose-piece arrangement of mirrors that we believe was a device taken from the microscope by Lindsay Johnson. The instrument thus completed has held the field ever since, even though adapted to an electric installation. Part of its success was due to the excellence of its manufacture, and it is of interest to note that British-made instruments are still a good deal superior to foreign-made ones.

Morton was chiefly a clinician. His careful precision in work was remarkable. His judgement in observation was associated with his power of delineating what he saw, for he was a first-class draughtsman, and could produce a fundus drawing that would have done credit to a professional artist. He was a tall man of dignified mien, slow of speech, not given to writing much, but a clinician whose judgement was of singular weight. He was for many years a member of the British Medical Association, and at the meeting of the Association held at Swansea in 1903 he read a paper on the operative treatment of conical cornea which was a perfect piece of work. The honour of office came to him, though he cared little for these marks of recognition. He served as vice-president of the Ophthalmological Society of the United Kingdom, and was for years a member of the Medical Society of Edinburgh. The Order of Chevalier of the Crown of Italy had been bestowed upon him for his professional services. His half-brother is Mr. Charles A. Morton, Emeritus Professor of Surgery in the University of Bristol.

JAMES MAXTONE THOM, M.B., C.M., D.P.H.,

Late Medical Superintendent, Glasgow Royal Infirmary.

DR. J. MAXTONE THOM, lately medical superintendent of the Royal Infirmary of Glasgow, has, to the deep regret of his many friends, not long survived his retiral from office. Dr. Thom was born in the town of Crieff in Perthshire in 1863. After graduating in medicine in the University of Edinburgh and taking the Diploma in Public Health at Glasgow he became medical officer of health for Auchterarder and Logiealmond, adjacent to his native burgh. When he had held this charge for six years he went to Glasgow to be medical officer of Barlinnie Prison and consulting medical officer of Duke Street Prison. In May, 1902, he was appointed medical superintendent of the Glasgow Royal Infirmary. He discharged his duties there with much acceptance for twenty-three and a half years, with one exception the longest tenure on record since 1838, when the post of superintendent was first established.

The period covered by Dr. Thom's term of service was one of the most momentous in the history of the Infirmary, including as it did the years of reconstruction and the problems created by the great war. In course of the reconstruction the whole Infirmary was built anew, the old buildings being completely replaced by a well equipped modern edifice. It is speaking evidence of Dr. Thom's unfailing tact and competence that this transformation was methodically carried through without any interruption in the normal services of the Infirmary. On the declaration of war Dr. Thom turned from these tasks to face new cares and anxieties. Throughout the whole of the grim-visaged time he played his part as superintendent with courage and high devotion, at a personal cost which in the end wore down his health and led to his resignation from office on December 31st, 1925. It was the hope of all that his release from active work might in great measure restore his strength and enable him to enjoy his well earned retirement for a number of years. Fate, however, had otherwise determined. He died on March 23rd last in a nursing home in Glasgow.

Temperamentally Dr. Thom was thoroughly suited for the charge which formed the chief work of his life. He was genial and kindly of disposition, and was gifted with the faculty of understanding, than which there is none more helpful to an administrator. He knew his hospital and his

people well. He enjoyed the esteem and confidence of his governors and the friendly regard of the members of his medical and surgical staff, who were always assured that in his conduct of affairs he was inspired by a wish to meet the reasonable requests of all in the best interests of the service than that the Infirmary claimed of him. The recreations of his leisure were fishing and golf. He is survived by his widow and a married daughter. His name will long be remembered with affection in the institution which he served so long and faithfully.

PROFESSOR DAVID MACEWAN.

WE regret that there was an error in the obituary notice of Professor David MacEwan of Dundee, published on April 9th (p. 703). It should have been stated that, at the Annual Meeting in Carlisle in 1896, he opened the discussion on hypertrophy of the prostate. The address in surgery was delivered by Dr. Roderick Maclaren, senior surgeon to the Cumberland Infirmary, Carlisle. It dealt with preventive surgery.

A Reuter's telegram from Capetown announces the death of Sir EDMOND STEVENSON, F.R.C.S.Ed., formerly president of the Medical Council, Cape Colony, of the Cape Branch of the British Medical Association, and of the South African Medical Congress. We hope shortly to publish a notice of his career.

The death is announced, in his 90th year, of Dr. ROBERT FULTON WEIR, at one time professor of surgery in the College of Physicians and Surgeons, Columbia University, New York; he was elected an honorary Fellow of the Royal College of Surgeons of England in 1900, in the first batch of such Fellows to be chosen.

Medico-Legal.

LUNACY CERTIFICATION.

De Freville v. Dill.

THE Court of Appeal, consisting of the Master of the Rolls, Lord Justice Scrutton, and Lord Justice Sargant, on April 11th dismissed an application by Mr. J. W. J. Cremlyn, on behalf of Mrs. May de Freville, the plaintiff in the action against Dr. A. V. Dill of Stroud—reported in the BRITISH MEDICAL JOURNAL of April 9th, p. 705—to have the jury who had been discharged by Mr. Justice Avory because they had formed a premature opinion adverse to Dr. Dill re-summoned and re-empanelled to hear the rest of the evidence.

Mr. Cremlyn, in making the application, said he had called fourteen witnesses for the plaintiff, and had closed her case, and the defendant had finished his evidence-in-chief and had been cross-examined for about an hour and a half when, the cross-examination not being completed, the foreman of the jury asked Mr. Justice Avory whether the jury could stop the case. The judge replied: "It depends entirely what views you take as to the evidence." The judge then told the jury to put their message to him in writing. The foreman did so, and handed it to the judge, who said that it was a finding by the jury that the defendant had been negligent, and returning a verdict for the plaintiff. Mr. Singleton, the leading counsel for the defendant, made no application for the jury to be discharged, but said that he could not consent to judgement in the circumstances. Thereupon the judge said that the proper course for him to adopt was to discharge the jury, as they had given a verdict without hearing material evidence for the defendant. The foreman said the jury had simply asked for advice, and had taken the advice given to put their opinion in writing. Mr. Cremlyn submitted that the judge was only entitled to discharge the jury if he had come to the conclusion that they had misconducted themselves, and had formed a dishonest, or corrupt, opinion.

Counsel for the defendant were not called on to argue.

Application Dismissed.

The Master of the Rolls, in his judgement dismissing the application, said the words used by the jury went far beyond a mere indication of a view passing through their minds. They were only consistent with an intention to stop the case without hearing the rest of the evidence for the defendant. It was plain that such a verdict must be bad. It was contrary to the oath taken by the jurors themselves well and truly to hear the case and to decide it in accordance with the evidence. Mr. meant the whole of the evidence, and not a part only of it. The intervention offended against the basic principles of justice. Mr. Justice Avory had exercised his discretion quite correctly, and he (his lordship) would be very sorry to say anything which might ve the effect of limiting or impairing the discretion of a judge discharge a jury in similar circumstances. The application st be dismissed with costs.

crutton and Sargant, L.JJ., gave judgement to the same effect.

Universities and Colleges.

UNIVERSITY OF LONDON.

A COURSE of three lectures on "The menstrual function, its physiology and pathology," will be given by Professor H. Beckwith Whitehouse at the London (Royal Free Hospital) School of Medicine for Women, Hunter Street, W.C.1, on Mondays, May 16th, 23rd, and 30th, at 5.30 p.m. Admission to the lectures is free without ticket.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary comitia of the Royal College of Physicians of London was held on April 11th at 5 p.m., the President, Sir John Rose Bradford, being in the chair.

The President delivered his annual address, in which he reviewed the work of the College during the past year. There was a considerable increase in the number taking the membership, the pointed out that there are now 379 Fellows. There was a contotal number of Members now being 836, as against 732 a year ago. He mentioned the honours conferred by the King upon Fellows, Members, and Licentiates of the College, and alluded to the gifts made to the College, including that from Colonel Sir Douglas Powell, Bt., of a replica of the portrait of his father, Sir Richard Douglas Powell, a former President, painted by Mr. Spencer Watson. Mention was also made of the revision of the by-laws during the past year, and special reference was made of the power that the College now assumed of granting Honorary Fellowships in special circumstances.

The President then delivered obituary addresses upon the career and work of the fifteen Fellows who had died in the past year, including Dr. E. S. Reynolds, Sir John Williams, Sir W. B. Leishman, Sir F. W. Mott, Dr. John Thomson of Edinburgh, Dr. J. G. Adami, Dr. Thomas Claye Shaw, Sir Isambard Owen, and Dr. Thomas R. Bradshaw.

Sir David Ferrier, the Senior Fellow present, then proposed a vote of thanks to the President.

Sir John Rose Bradford was re-elected President for the ensuing year.

Diplomas in Tropical Medicine were granted, jointly with the Royal College of Surgeons, to the following twenty-four candidates who had passed the required examination:

S. Annecke, E. G. Anthonisz, A. C. L. O'S. Bilderbeck, Catherine Y. Burne, N. P. Dalal, T. B. Gilchrist, R. D. Gross, Kathleen M. Halloran, R. G. Keays, H. H. W. Kumm, F. R. Lockhart, A. D. Logandan, P. H. Martin, F. R. L. Miller, Margaret M. Nolan, J. Portelli, Helen M. Russell, E. G. Sayers, H. M. Shelley, Viva E. K. Stuart, H. S. Townsend, Bertha Williamson, C. J. Wylde, W. A. Young.

Medical News.

AT the annual meeting of the Tuberculosis Society, held at Somerville College, Oxford, Sir StClair Thomson was elected president, and the council was instructed to consider the constitution of the society and to recommend alterations if necessary.

As a sequel to Sir Berkeley Moynihan's broadcast talk on Lord Lister from the Leeds-Bradford station of the British Broadcasting Corporation on April 8th, Sir Charles Hyde has endowed a bed in the following five Birmingham hospitals: General, Queen's, Children's, Orthopaedic, and Women's.

AMONG the Chadwick Public Lectures to be delivered this session is one by Sir Thomas Legge, C.B.E., M.D., on the teaching of industrial medicine. It will be given on Tuesday, May 3rd, at 5.15 p.m., in the house of the Medical Society of London (11, Chandos Street, Cavendish Square, W.), and Dr. S. Monckton Copeman, F.R.S., will be in the chair. Admission is free.

THE annual meeting of the Medical Mission Auxiliary of the Church Missionary Society will be held at the Central Hall, Westminster, on May 4th, when Bishop H. Gresford Jones (late of Kampala) will take the chair at 7.30 p.m. The speakers will include Dr. A. R. Cook, C.M.G., from Mengo, Uganda, and Dr. D. Duncan Main from Hangchow, China. Tickets of admission can be obtained from the Superintendent, Loan Department, Church Missionary Society, Salisbury Square, E.C.4.

DR. EDWARD MAPOTHER, Medical Superintendent of the Maudsley Hospital, Denmark Hill, S.E.5, will give a series of five clinical demonstrations at the hospital on types of mental disease, on Wednesdays, at 2.30 p.m., beginning on April 27th.

THE Langley prize of the London School of Hygiene and Tropical Medicine is now open to competition among officers of the West African Medical Staff, whether on the active or retired list. The prize, founded in memory of Dr. W. H. Langley, C.M.G., P.M.O. Southern Nigeria, is awarded every three years; the first award was made in 1924. It is given for the best paper on tropical medicine or surgery, hygiene, or epidemiology and parasitology. It is of the value of £30. The papers in competition must be received by the Secretary of the London School of Hygiene and Tropical Medicine, Malet Street, London, W.C.1, on or before October 1st.

THE Ministry of Health has amended the regulations in connexion with the use of preservatives in food, which came into operation on January 1st. The manufacture for sale of an article of food containing any preservative introduced by the use of preserved bacon, ham, or margarine is now prohibited, and the restriction on the use of sulphur dioxide is slightly modified. In a circular (782) attention is called to the Sale of Food and Drugs Act, 1927, which gives effect to the recommendation of the Departmental Committee on Preservatives and Colouring Matters in Food that any prohibitions or limitations imposed by the regulations should bind the Courts in proceedings taken under the Sale of Food and Drugs Acts. Previous references to the regulations dealing with preservatives in food appeared in our issues of August 22nd, 1925 (p. 349), and January 8th, 1927 (p. 70).

APPLICATIONS for the Moorfields Research Scholarship of the value of £50 a year must be sent to the Dean of the Royal London Ophthalmic Hospital, City Road, E.C.1, by May 15th. The successful candidate will conduct clinical research at the hospital.

THE date of opening of the eighth Salon des Médecins at Paris has been postponed to May 22nd.

BOOTS PURE DRUG COMPANY, LTD., are extending their research work at Nottingham, and have appointed as head of the research laboratories Dr. F. L. Pyman, F.R.S., professor of technological chemistry in the University of Manchester and in the College of Technology. A primary object of this new development is the prosecution of fundamental research in the domain of chemotherapy. Professor Pyman is well known for his investigations into the chemistry of the alkaloids and of synthetical compounds closely related to them; recently he has devoted much attention to the glyoxaline group, and has effected a synthesis of one of the most important members of the series—namely histidine, a structural unit of certain protein molecules.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

QUERIES AND ANSWERS.

DELIVERY IN CONTRACTED PELVIS.

"A. K." asks for advice in the conduct of the following case: A woman, then aged 25, had her first child three years ago. The presentation was a breech; each hand had to be brought down and forceps applied to the after-coming head. The child, though small, was dead. The next year she had an abortion at two and a half months, when it was found quite impossible to get an ordinary-sized hand through the pelvic brim to evacuate the ovum from the uterus. Now she is six months pregnant again. She does not like the idea of waiting for a possible Caesarean section, but has no objection to induction of premature labour. What would be the period at which to act and by what method? The use of bougies is rather risky in the circumstances.

*** A patient giving a history as outlined by our correspondent requires the most careful attention, preferably from an expert and in a hospital. The pelvic measurements must be accurately estimated to form an opinion as to whether a *viable* child is possible *per vias naturales*. Caesarean section at term seems the best—in fact, the only reasonable line of treatment for the safety of both mother and child, because the pelvic brim has been found too small to allow the passage of a normal-sized hand. This treatment could be justifiably insisted upon by the patient's medical attendant. If a Caesarean section is absolutely refused, then the only alternative is the induction of premature labour at a time when the foetal head will only just enter the brim of the pelvis. If that time is reached earlier than the thirty-sixth week of pregnancy, then induction is contraindicated in the interests of the child. Should induction be insisted upon, then there is no serious objection to Krause's bougie method.

ATONY OF THE COLON.

"N. A. M." asks for suggestions for treatment for complete atony of the colon. Eserine gives rise to pain without evacuation, and no result is obtained from the usual purgatives; enemas give only indifferent results. Laparotomy was performed, but beyond general laxity and ballooning of the pelvic colon, nothing *abnormal was found.*

INCOME TAX.

Succession to Practice.

"A. B. C." sold his practice to F. as from May 1st, 1926, the arrangement providing for a six months' partnership, on a basis of equal shares, ending at that date. He has been assessed on a cash basis for many years and has supplied figures accordingly for the period expiring March 31st, 1926, but has since been asked for a separate statement of the partnership profits for the six months to April 30th, 1926.

*** So far as the year 1925-26 is concerned, "A. B. C.'s" gross liability would be determined by (1) the "average" assessment for seven months *plus* (2) one-half of the average for five months—that is, it would be represented by $(\frac{7}{12} + \frac{5}{24} =) \frac{19}{24}$ of the assessment. His personal allowances, etc., would be deductible from that amount. For the month of April his liability would be fixed by one-half of one-twelfth of the "average" assessment, and the average would be affected to some extent by the earnings during the six months' partnership. It may be for that reason that the latter figures were required, but there is another possibility. If the profits of the partnership—which technically "succeeded" to the sole practice—fell short from some specific cause since or by reason of the succession, "A. B. C." and his partner would be entitled to have the assessment for that period reduced to the actual amount of their earnings. But it should be borne in mind that the cash basis would not be applicable unless the receipts from pre-partnership debts were brought into the partnership earnings.

Old Book Debts.

"FOGGED" sold his practice on April 1st, 1926, buying another as from January 1st, 1927, after a quarter's introduction on a half-share basis. Has he to include in his return any cash he is receiving in respect of his former practice?

*** As for the year 1926-27, our correspondent has ceased to carry on his former practice and is not assessable in respect of any sums he may receive from it; they represent capital in the form of past book debts. The basis of computation of liability in respect of his new practice appears to be correct.

LETTERS, NOTES, ETC.

RHEUMATIC INFECTION IN CHILDREN.

DR. T. M. ALLISON (Newcastle-on-Tyne) writes: The second report on juvenile rheumatic infection is based upon and deals with the following aspects: (1) a micro-organism, (2) tonsillar infection, and (3) environment. There is, in my opinion, an unnamed fourth factor—namely, *mouth-breathing*. The mouth is to eat bread-and-butter with; the nose is to breathe through. I have rarely, if ever, seen rheumatism except in a mouth-breather, and one can almost always elicit a history of snoring. Mouth-breathing accounts for tonsillar infection; *it dries* and prepares the tonsils for the inhaled organism, and it accounts for the influence of dampness and the cold air of the bedroom making the arthritic pains worse, in spite of the rest and the warmth of the bed. In your leading article in the BRITISH MEDICAL JOURNAL it is stated that the second report "deals rather with treatment than with prevention." May I suggest that the prevention of rheumatism in childhood lies in the prevention of mouth-breathing, and that in adults (where operation may be futile) that it lies in the use, especially at night, of a carbolic mouth-wash?

CORRECTION.

IN the report of the meeting of the South Wales and Monmouthshire Branch in the issue of April 16th (p. 721), Dr. Emil Goetsch should have been described as "of Brooklyn," and in the last sentence "solid shadow" should have read "heart shadow."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 40, 41, 44, and 45 of our advertisement coln [illegible] 43. and [illegible] notified in the advertisement columns appears in the Supple[illegible] at page *164*.

A British Medical Association Lecture
ON

ASTHMA IN CHILDHOOD.

DELIVERED BEFORE THE SWANSEA DIVISION ON FEBRUARY 24TH, 1927,
BY

ROBERT HUTCHISON, M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL, AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

ASTHMA is always an interesting disease, but it is specially interesting in childhood, not only because we meet it then in its earliest and simplest forms, but also because it is then that we have the best chance of curing it. Relatively, too, it is commoner in the child than in the adult, for about one-third of all cases begin below the age of 10 and many start during infancy. Like all the diseases of childhood in which nervous influences play a large part, it is more frequently met with amongst boys than amongst girls.

There are four varieties or types of "asthma" in childhood:

1. The *Spasmodic* type, which presents the classical picture of recurring episodes of the characteristic asthmatic dyspnoea. This type is commonest in older children.

2. The *Hay Fever* type, in which nasal catarrh is the most prominent feature. Such cases are apt to be regarded as simply recurrent "colds in the head."

3. *Bronchial Asthma*, in which there is, at the outset, a good deal of bronchitis, to which spasm of the tubes becomes superadded. Cases of this type are very common, and the attacks are often prolonged.

4. The *Bronchitic* type, which is peculiar to children, especially babies, and in which the asthma masquerades as a pure bronchitis, so that the real nature of the condition is often overlooked. It is distinguished from a simple bronchitis by the suddenness of the onset and subsidence, by the fact that dyspnoea precedes the appearance of physical signs in the lungs, by the comparative absence of fever, and by the presence of an eosinophilia.

Thymic Asthma.—In infancy asthma may be simulated by the rare condition called "thymic asthma," or "paratroplied thymus or enlarged bronchial glands. Thymic asthma always begins before the age of 18 months, and is distinguished by the presence of the physical signs of enlargement of the thymus or of the bronchial glands. A screen examination is of great help in the diagnosis.

THE NATURE OF ASTHMA.

The dyspnoea of asthma is attributed, as is well known, to obstruction of the bronchi either from spasm of the muscle or from swelling of the mucous membrane, or from both these acting together. The obstruction, whicherer form it takes, may be brought about either (1) through the respiratory centre, or (2) by direct action on the bronchial mucous membrane. We must consider each of these modes separately.

1. The respiratory centre may be affected (*a*) psychologically, (*b*) reflexly, (*c*) by the blood.

(*a*) Amongst psychological influences may be mentioned fright and excitement (both of which are specially potent in determining an attack in children), and suggestion, the part played by which in early life is difficult to determine.

(*b*) The chief sites of peripheral irritation which may affect the respiratory centre reflexly in children are the nose and throat and the alimentary canal. Phimosis would also appear to be an occasional cause.

(*c*) The centre may be affected directly by the blood circulating through it in the way to be described immediately.

2. The changes in the bronchi which lead to obstruction may also be brought about directly and without the intervention of the respiratory centre by the presence in the blood of a specific substance which acts as an irritant. The substance in question is believed to be of the nature of a foreign protein or "allergen" to which the asthmatic subject is "sensitive." Some seem to be born with this sensitiveness, others acquire it, others have it "thrust upon them" by disease or accident.

It may be a constitutional peculiarity, often inherited. Such an inborn metabolic irritability may reveal itself by producing, not asthma alone, but other episodic disturbances such as migraine and cyclical vomiting, as well as skin disorders like eczema and urticaria. Such patients are usually sensitive to several proteins, but the degree and character of the sensitiveness may vary from time to time and may come and go suddenly. Sensitiveness may be acquired as the result of an overdose of a foreign protein. It is said, for instance, that an infant may sometimes become sensitive to egg in consequence of being given large quantities of albumin water, and sensitization after the injection of serum is, of course, well known. Sensitiveness may also be "thrust upon" a patient by an operation, particularly, perhaps, an operation on the throat.

Such an asthmatic child, therefore, may be born with an unstable metabolism, or it may have been thrown off its metabolic balance in one of the ways described. Our experience at the Hospital for Sick Children (Great Ormond Street), however, has been that sensitiveness is this way in children—or by an operation, particularly, a factor in less than half of all cases of asthma in childhood, and that even when it is present it is only in a small number that the specific excitant of the asthma can be determined. It would seem, indeed, as if sensitiveness is more often a predisposing condition as regards asthma in children than the actual cause of it.

Where sensitiveness is the cause the protein to which the patient reacts may reach the blood in various ways.

Ingestion.—First, it may be ingested in the form of food. Almost any food may produce a reaction, even—perhaps especially—such common ones as the proteins of eggs and milk. Sensitiveness to food protein is usually inborn, and tends to disappear with time. It is therefore more likely to be a cause of asthma in early childhood than in the later years.

Inhalation.—Secondly, the protein may be inhaled in the form of dust of various kinds—pollen and so forth. This form of sensitiveness is oftener acquired than inborn —though even when acquired there has probably been an inborn tendency to metabolic instability—and is more persistent than sensitiveness to food protein, having less tendency to disappear of itself. It is of more importance in the causation of asthma than sensitiveness to the protein of foods.

Bacteria.—Thirdly, there is some reason to believe that the protein to which an asthmatic patient is sensitized may be of bacterial origin and derived from organisms growing at some seat of chronic infection, of which the commonest is probably the nasopharynx. So-called bronchial asthma is the form of the disease most likely to arise in this way.

The fact that a patient is "sensitized" can often be inferred from his history. Thus one of my patients had attacks only when living on a farm in close contact with animals, whilst another was only asthmatic when living in the neighbourhood of trees. Sensitization to common articles of food or to dust is more difficult to detect, but by the use of the cutaneous test with watery extracts of different proteins the question whether and to what the patient is sensitive can be definitely determined. I think it is advisable to use such tests in all asthmatic children, but at the same time I am bound to say that I have been disappointed in the results of treatment based upon them. This matter, however, will be referred to immediately.

TREATMENT.

Treatment of the Attack.

Treatment of the attack of asthma is much the same as in the adult. Subcutaneous injection of adrenaline (2 to 3 minims) is the best remedy, and acts by antagonizing the action of the vagus and stimulating that of the sympathetic. Morphine, though effective, has to be used cautiously in childhood, and children do not like "fumes."

Treatment of the Tendency.

More important is the treatment of the asthmatic tendency. Here the chief thing to realize is that "asthma" is not a disease of the respiratory system only, but one of the child as a whole, and that treatment must aim at breaking the asthmatic habit, for, as someone has put it, "the best cure for asthma is not to have it."

In the general management, therefore, the patient's whole life must be regulated, and nervous excitement and overstrain particularly guarded against. At the outset the question of "coddling" *versus* "hardening" will obtrude itself, and is not always easy to answer. Whilst we must carefully avoid making the asthmatic child a "hot-house plant" invalid, it must also be admitted that needless exposure to weather, especially fog and damp, is injurious, particularly in the bronchial type, and we must not make a fetish of fresh air. The question of climate also arises at this stage, and we shall be asked whether a permanent change is desirable. As to this it is unwise to be too dogmatic. All we can say is that a warm, dry climate is theoretically the best—again especially in the bronchial type—but such a climate is not to be had in these islands. Mere change of locality is highly speculative, and is apt to be only an escape from the frying-pan into the fire. It is true that some patients seem to be much freer from attacks in one place than another, but this may be due to some factor other than the climate—removal, for example, from the immediate neighbourhood of animals. Certainly we should never advise the parents to change their place of residence unless they have satisfied themselves by a prolonged trial that the child is free from the disease in the place to which they propose to move. My usual advice is that they should endure the evils they know rather than fly to others that they know not of. Immunity from attacks is usually obtained at an altitude of 5,000 feet, but this is impracticable as a permanent place of abode, and the attacks recur so soon as the patient returns to a lower level.

Diet is of importance, for experience has shown that improvement often results from the avoidance of "indigestible" things, and the provision of small dry meals with no supper. Carbohydrates should be avoided rather than fats. In children, however, it is not wise to cut down the diet so rigidly as can often be done with advantage in the adult, for the needs of growth have to be provided for, and the child must not be sacrificed to the disease. If tests have shown that the child is "sensitive" to any particular article this should, of course, be banished from the diet, but my experience has been that it is only in exceptional cases that this has much effect on the disease.

Drugs.—The drugs which might be expected to be of use in asthma are those which lessen vagus action and those which diminish the excitability of the respiratory centre. Belladonna and its allies act in the former way, arsenic is said to act in the latter, and there is no doubt at all of the great benefit often derived from them in cases of asthma in childhood. I am in the habit of giving small doses of potassium iodide (especially where there is a bronchial element) along with full doses of belladonna or stramonium and arsenic as a routine. The mixture should be given regularly after meals for prolonged periods, and, so used, often effects great improvement. I have seen this happen too often to have any doubts of the real curative value of such a combination, and, indeed, I regard it as on the whole the best treatment for asthma in children. For the purpose of warding off a threatened attack a full dose of a sedative such as chloral at bedtime is often very helpful. Antipyrine sometimes acts equally well.

Operations.—The question of removing enlarged tonsils and adenoids in asthmatic children will often arise, and if the enlargement is causing obstruction, or if the tonsils are infected, it is best to operate. It is unwise, however, to make any promise as to the effect on the asthma, but benefit is most likely in cases of the bronchial type. On the other hand, I have, like everyone, known several cases in which asthma appeared for the first time after the removal of tonsils and adenoids. Of the effects of cauterization of the nose for asthma in children I have had very little experience.

Vaccines.—A course of vaccines is worth trying in cases of the bronchial type, using for choice an autogenous vaccine prepared (if possible) from sputum obtained during an attack. The results, however, are extremely uncertain, though at least it may be said that the treatment can do no harm. When it is successful—and I have seen cases where it certainly seemed to be—it is always doubtful whether the benefit obtained is due to a raising of the resistance to infection or whether the vaccine has really acted as a desensitizing agent. That, however, is an academic question.

Specific Treatment.

If the child is known to be a "sensitive," removal of the offending agent from his environment is, when possible, always to be advised, though here again definite cure should not be promised. In all such cases, too, it is wise to forbid the use of feather pillows, hair mattresses, fur coats, as well as horse-riding and the keeping of pets, for even if the patient is not "sensitive" to any of these already he may easily become so. These, however, are elementary precautions, and the ideal to be aimed at is a general desensitization which would, so to speak, cut the ground from under the feet of the asthmatic process. Unfortunately, however, the technique of desensitization is still only in the experimental stage, and so far I am bound to confess that I have been disappointed with the results in those cases—admittedly few in number—in which I have tried it. Various substances have been suggested as desensitizing agents—peptone, milk, some of the child's own blood, tuberculin, and cultures of organisms prepared from the nasopharynx or from the bowel. Of these I have had most experience with peptone, usually given intravenously. It is necessary to proceed cautiously, and it is difficult to regulate the dose, for when an asthmatic child is admitted to hospital the asthma usually disappears for a time at least, and so there is nothing by which to gauge the effect of the treatment. On the whole, I think I may say that our experience at the Hospital for Sick Children has not borne out the high opinion of the treatment which has sometimes been expressed. It is quite possible, nevertheless, that when the technique of the method has been more elaborated it may prove to be of great value in those asthmatics in whom sensitiveness exists. It must be remembered, however, as has already been pointed out, that these constitute a minority. Of general radiation, a method of treatment recently advocated by Dr. Gilbert Scott,[1] I have had no experience. It seems possible that it acts by general desensitization.

PROGNOSIS.

Finally, a word as to the outlook for the asthmatic child. The immediate attack is, of course, rarely dangerous except in young or delicate infants. Assuming that preventive treatment fails, what chance is there of the attacks being "outgrown"? A very fair chance indeed. I have been agreeably surprised, when following up cases of asthma, seen often several years ago, to find in how large a proportion the attacks have either ceased altogether or have become few and slight, although where the disease has lasted for several years there may be some resulting emphysema and some stunting of growth and development. On the whole, however, the outlook for the asthmatic child is much brighter than the inexperienced would suppose.

REFERENCE.

1 BRITISH MEDICAL JOURNAL, June 5th, 1926, p. 939.

A British Medical Association Lecture ON THE TREATMENT OF INFANTILE PARALYSIS.

DELIVERED BEFORE THE MONMOUTHSHIRE DIVISION, DECEMBER 10TH, 1926,

BY

ARTHUR ROCYN JONES, B.S.LOND., F.R.C.S.ENG.,
SURGEON, ROYAL NATIONAL ORTHOPAEDIC HOSPITAL; CONSULTING ORTHOPAEDIC SURGEON, MONMOUTHSHIRE COUNTY COUNCIL.

THERE is no disease more productive of permanent disability in children than infantile paralysis, but fortunately much crippling can be prevented by well guided early treatment. The malady is always among us in a sporadic form, but it is many years since we have had an epidemic comparable to that which has occurred recently at Broadstairs and Leicester. Although infantile paralysis has been recognized for nearly a century, yet most of our knowledge has been accumulated during the last thirty years, mainly through experience gained when the disease has assumed an epidemic form in various countries. In 1905 it spread all over Sweden, and since 1907 there have been periodical epidemics in the United States of America.

Poliomyelitis attacks children in all grades of society and is not necessarily associated with poor housing conditions. There is strong reason for thinking that it is a disease disseminated from person to person, and although the causal agent is not known it is believed to be a minute filterable organism[1] invading the body by the mucous membrane of the nasopharynx. Passing through the mucous membrane the poison gains the blood stream by way of the lymphatics, and, spreading widely, produces a general infection.[2] The main onslaught, however, is directed against the central nervous system, and the motor nerve cells of the grey matter in particular. These last suffer from a threefold attack[2]—namely, mechanical pressure due to oedema and cellular infiltration of the surrounding nervous tissue; anaemia through rupture or constriction of their arterioles; and intoxication due to the direct action of the virus. The site, extent, and virulence of the attack determine the prognosis. Bulbar lesions account for many of the fatal cases; in lesions of the cord alone, which are much commoner, the mortality is comparatively low. Recovery of the motor nerve cells and the disappearance of the paralysis will depend upon whether the initial attack causes complete cellular destruction, in which case the paralysis is absolute and irrecoverable, or whether the cells, having survived the first onslaught, are only temporarily unable to function through persistent pressure from haemorrhagic exudate and oedema, the gradual absorption of which brings relief. Should the exudate, however, become organized and replaced by fibro-cicatricial tissue, then some cells may remain permanently functionless from scar pressure. Although there is no means of determining the nature of the pathological lesion and forecasting the ultimate prognosis, yet it can be said that there is in most patients a strong tendency towards spontaneous recovery.

The symptoms of onset, apart from the paralysis, resemble those of other acute specific fevers. The incubation period is probably from four to ten days, during which there may be some sore throat. The onset is sudden, accompanied by fever up to 103° F., sweating, vomiting, sometimes diarrhoea, and general nervous irritability. One or more limbs are paralysed and flaccid. There are various clinical types, which are classified by Müller as spinal, bulbar, cerebral, and abortive. The bulbar form, as already mentioned, presents an unfavourable outlook owing to possible involvement of vital centres. Several fatal cases of this type have been reported by Feiling,[3] Collinson,[4] and others. The cerebral form (polio-encephalitis) may be confused with meningitis, and being an upper motor neurone lesion is characterized by spastic paralysis. The abortive form gives rise to an interesting group, and was first recognized by Caverly[5] in the Vermont epidemics. Many of the acute initial symptoms are present but paralysis is absent. This form occurs frequently during an epidemic, but owing to the absence of paralysis is apt to be missed, and thus a patient of this type may become an unchecked carrier. If doubt exists, a lumbar puncture will help to clear the diagnosis. The cerebro-spinal fluid will show white cells from a hundred upwards in each cubic millimetre, three-quarters of them being polymorphonuclear. Organisms are absent and the glucose and chloride content are both normal.

The spinal type is the commonest paralytic form, and the following remarks apply mainly to this group of cases. There are three clinical periods of the disease—the acute, the quiescent, and the chronic. The acute stage is ushered in by the symptoms indicated. The limbs are painful and tender to touch, and this may last with declining severity for six weeks. It should be added, however, that frequently in the sporadic case no history of an acute onset is obtained; the child goes to bed apparently well, and the next morning the mother finds one limb powerless and hardly any other symptom to suggest an acute infection. Muirhead Little,[6] in a careful investigation of 115 cases, describes the sudden appearance of paralysis in 43, and in 19 of these the paralysis was the first symptom to attract attention. With the passing of muscular tenderness the second or quiescent stage begins, and with it spontaneous recovery of the muscles. Improvement continues for approximately two years. When recovery comes to a standstill the third or chronic stage has arrived.

TREATMENT.

The virus is present in the mucous membrane of the nasopharynx of infected persons, and therefore contacts should cleanse their throats by gargling three times a day with a 1 in 4,000 solution of potassium permanganate.

First Stage.

The patient should be isolated for four weeks and all the excreta disinfected. In the pre-paralytic stage the intraspinal injection of 5 to 20 c.cm. of human immune serum, obtained from patients who have recovered from the disease, has been advocated, and many cases have been so treated in America and New Zealand. The practical difficulties in providing serum are obvious, although the municipal authority of Melbourne[7] succeeds in obtaining and storing it for emergency. In this stage, too, urotropine[8] has its greatest value. The objection to it is its tendency to produce bladder irritation, but this can be obviated and large doses tolerated by keeping the urine alkaline with sodium bicarbonate and potassium citrate, as recently suggested by Hurst.[9] Urotropine is of doubtful value when the disease is well established.

The pain and tenderness suggest that rest in bed is the best treatment in this stage. The joints should be kept in a neutral position to prevent deformities arising and to relax opposing muscles as much as possible. The child should lie on a flat bed with the thighs slightly abducted, the knees straight, and the feet at right angles to the legs. Sandbags and properly arranged towels will help in maintaining this position. It is a great advantage, however, to put the limbs in splints or plaster gutter casts. A pair of long moulded splints extending from just below the buttock to the back of the heel and then along the sole of the foot will keep the knee and ankle joints in the correct position. A flat bed will help in preventing scoliosis developing if there is paralysis of the spinal muscles on one side. If an upper limb is paralysed the arm should be abducted, the forearm flexed and supinated, and the hand slightly dorsiflexed. These positions of the limbs are the best in the early stages and where it is not yet clear what muscle groups are most affected, but where it is obvious that some muscles are paralysed and their opponents have escaped, then it is well to follow the rule laid down many years ago by Sir Robert Jones[10] and allow greater relaxation of the weakened group—for example, in a drop-foot paralysis with the tendo Achillis unaffected, the foot should be dorsiflexed slightly beyond a right angle and the splint adapted accordingly. No other treatment is necessary during this stage. Massage and electrical treatment of these tender muscles are to be strongly deprecated. They add to the discomfort of the patient and may do infinite harm. But this should be

explained to the parents, who will need reassuring that, having splinted the limbs, the best service to the child is to stand and wait in the early weeks.

Second Stage.

When tenderness has disappeared from the muscles, which is usually somewhere about the sixth week, more active treatment is undertaken. Accompanying the paralysis there are trophic disturbances such as local impairment of the circulation. The muscles are flabby, and the limb is cold and has a blue tinge. The aim of treatment should be to maintain the nutrition of the muscles until restoration of function is established. This is best attained by keeping the limb warm, applying gentle massage and the galvanic current. But it should be clearly understood that neither massage nor electricity has a direct influence on recovery. The most that can be said for either is that they keep the muscles in a state prepared to receive impulses. The splints should continue to be worn and great care taken, during the massage, that the paralysed muscles are not stretched. After two or three weeks of massage the child should begin to be propped up on a bed-rest, and later may be allowed to sit in a chair propped up with pillows. All this is preparatory to getting the child on its feet. By this time the muscles will have shown indications of recovery. Even a small contraction in a muscle can be felt by fingers placed on its tendon, and once a voluntary contraction occurs much can be done to hasten further recovery by graduated exercises. But in doing this great care is necessary to avoid overloading the muscle—for example, if the foot dorsiflexors are paralysed it will not do to let the foot drop and expect the recovering muscle to lift it. The foot should be supported almost to right angles and the patient then asked to dorsiflex. In all these exercises, which are valuable in restoring bulk and tone to the muscles, the burden must be accommodated to the strength of the muscle.

The time when a patient may be allowed to stand will vary with each individual case, but in many with lower limb paralysis it will be from three months upwards from the onset of the disease. If the paralysis has disappeared walking should be undertaken by stages, but fatigue avoided. If some paralysis remains, then walking appliances will be necessary, depending upon the disability—for example, with paralysed quadriceps, peronei, and foot dorsiflexors, a calliper with uplifting toe-spring and outside T-strap and wedge on the boot will keep the knee straight, the foot dorsiflexed and everted at the ankle. By this means all the paralysed muscle groups are kept relaxed. The splints first prescribed should still be worn during the night and the graduated exercises and massage continued. At the end of the year recovery slows down considerably, but it may still go on for yet another year. It is very unlikely that any improvement will take place after two years in a patient who has been continuously under well directed treatment from the beginning. But during this time every care should be taken to improve the general health, for this helps in the recovery. Fresh air and sunshine are useful adjuncts in this respect. Children in the second stage treated at the Royal National Orthopaedic Hospital at Brockley Hill react favourably to graduated sun exposure, but whether it is due to the increased metabolism thereby produced is difficult to say.

Third Stage.

When, in spite of treatment, recovery has ceased and the condition has remained stationary for some months, then the last or chronic stage has been reached. The residual paralysis then represents the extent of permanent disability, but two or three years at least from the onset should be allowed to elapse in a well treated case before this disability is accepted as incapable of further non-operative improvement. This, of course, applies only to cases where deformity has been prevented and where the disability is essentially a paralytic one. Where, however, as frequently happens in the neglected case, deformity is present, this should first be corrected and the overstretched paralysed muscles given some months to recover with the joint in a favourable position.

the lower limb the commonest deformities needing correction are flexion of the hip and knee, and plantar flexion at the ankle. In flexion of the hip the tightened tensor fascia femoris usually prevents correction, and is best dealt with by Soutter's[11] operation. A longitudinal incision three inches long is made in the long axis of the body with its centre two inches posterior to the anterior superior iliac spine. The tensor fascia femoris is exposed and cut transversely. The muscles and fascia are lifted subperiosteally by an osteotome from either surface of the anterior superior iliac spine. The muscles are pushed back leaving the bare spine projecting, which is then removed by an osteotome. The hip is hyperextended and the wound closed. The patient is nursed for six weeks on half mattresses extending from the head to the buttocks, allowing the hip to be hyperextended, or a plaster-of-Paris cast may be applied from the chest to the ankle. Flexion at the knee can be overcome by extension in a bed calliper, but in intractable cases open elongation of the hamstrings may be necessary. An equinus deformity due to the contraction of the tendo Achillis can often be overcome by dorsiflexing the foot under an anaesthetic, but if this fails open elongation of the tendon should be undertaken, allowing the foot to be brought just up to a right angle with the leg. A varus deformity usually responds to manipulation. Splinting, massage, and graduated exercises should follow the correction of deformity to see if any recovery in the affected muscles takes place. If this happens, the treatment should continue until improvement ceases. But before considering further measures it is worth while allowing this type of case also to be up and walking, properly splinted, for some months.

After sufficient time has elapsed to show that further recovery from the paralysis is unlikely, and where any deformity present has been corrected, there still remain means by which function can be improved, although the paralysis is permanent. Each case presents its own peculiar problem, and therefore principles of treatment only can be mentioned here.

The object of operative treatment is to produce joint stability and dispense with the necessity of wearing an appliance. The methods which find most favour for this purpose at the present time are arthrodesis, tendon transplantation, and tendon fixation, and sometimes two of these methods may be combined.

Arthrodesis was introduced by Albert of Vienna in 1878, when he deliberately ankylosed a flail knee, but now the only common site for the operation is the tarsus; a flail shoulder is occasionally stiffened, but only where there are good scapular muscles to ensure later good movement of the combined humerus and scapula. Arthrodesis of the knee and ankle are seldom performed. For a flail foot where instability is in front of or below the ankle, at the astragalo-scaphoid and astragalo-calcanean joints, the so-called triple arthrodesis is valuable. The astragalus, os calcis, cuboid, and scaphoid are converted into one bone by the removal of their opposing articular cartilages, thus allowing ankylosis to take place by encasing the foot in plaster-of-Paris for eight weeks. But this operation is preferably done at the age of 12 years or over, when the tarsal bones are well ossified. Where the instability is at the ankle-joint, or in cases where the tendo Achillis and tibial muscles are paralysed, producing a calcaneo-valgus deformity of the foot on standing, the best result is obtained by Whitman's operation,[12] which consists of performing astragalectomy and pushing the foot backwards until the fibula overlaps the calcaneo-cuboid joint; the foot is held in a slight equinus position and encased in plaster-of-Paris in this position for three months. A boot with a long heel part to the upper will be required afterwards. One of the cases shown here to-day had a Whitman's operation performed on the left foot for a severe paralytic calcaneo-valgus deformity and a triple arthrodesis for a right flail foot. The patient now walks quite well without appliances, notwithstanding that the right quadriceps is very weak.

Tendon transplantation was first introduced in 1881 by Nicoladoni. Operating upon a case of paralytic calcaneus, he cut the peronei and implanted their central ends into the tendo Achillis. The success of tendon transplantation depends upon the muscle selected for transference and the

manner in which it is grafted. The chosen tendon should be a normal one of good power—a weak muscle is useless. The tendon should be brought down along a gradual path to its new insertion; a sudden twist or turn in its course is fatal to its working efficiency. Where possible it should be inserted into bone. One of the most successful transplantations is the transference of the tibialis anticus to an insertion into the cuboid to act as an everter of the foot where the peronei are paralysed. [In one of the cases shown the peroneus brevis had been grafted into the tibialis posticus to aid inversion of the foot in paralytic talgus.] The transplanted tendon should be relieved of all strain for at least two months, and if the appliance has been worn this should be continued for a little while longer.

Tendon fixation originated in 1898 with Tilanus of Amsterdam when operating upon a girl with paralytic equino-varus. The tendo Achillis was cut subcutaneously, the extensor proprius hallucis was then cut by open section and the central end attached to the extensor longus digitorum, and the peripheral end to the periosteum of the tibia. Codivilla extended the method further, and latterly Gallie[13] of Toronto has brought it prominently forward. The paralysed tendons are converted into ligaments to correct the disability[14]—for example, in paralytic varus the paralysed peronei are permanently fixed to the external malleolus so as to check the deformity. Two grooves are gouged—one on the anterior and the other on the posterior aspect of the external malleolus. The tendons are pulled taut, correcting the deformity, and are buried in these grooves, the longus in front and the brevis behind. The periosteum is brought over and sewn to the tendons, and the foot is encased in plaster-of-Paris for two months. The cast is then removed and the patient allowed to walk without an appliance.

In some cases the paralysis is so extensive that an instrument is a permanent necessity, for no operation is likely to succeed in dispensing with it. One child seen here to-day had not walked for four years owing to complete paralysis of the lower limbs with fixed hip and knee flexion. Soutter's operation was performed on each hip and the knees were straightened by extension. This enabled her to be fitted with callipers and so to walk about. There are exceedingly few cases so badly paralysed that they cannot be made to walk. Even if three or four limbs are paralysed, provided there remains sufficient power in the hands to grasp a pair of crutches, walking is still possible by means of artificial support.

THE TREATMENT OF CONGENITAL SPASTIC PARAPLEGIA BY SYMPATHETIC RAMISECTION.

BY

N. D. ROYLE, M.D., CH.M.SYDNEY,

HONORARY ORTHOPAEDIC SURGEON, LEWISHAM HOSPITAL; HONORARY ORTHOPAEDIC SURGEON, STATE CHILDREN'S RELIEF BOARD, NEW SOUTH WALES.

DR. N. D. ROYLE has contributed to the *Medical Journal of Australia* the full text of a paper on the treatment of congenital spastic paraplegia by sympathetic ramisection. By arrangement with the editor of our contemporary the following abstract appears simultaneously here.

It had occurred to Dr. Royle that in spastic paralysis the resistance offered to the moving group of muscles by its antagonists was due to a fault in reciprocal innervation; and when, subsequently, the discovery was made that the voluntary muscles have a dual innervation, he carried out a series of experiments on goats to ascertain whether any deductions could be drawn as to the part played in the causation of the spasticity by the sympathetic element in this dual innervation. The results were published in the *Medical Journal of Australia* in January, 1924.

EXPERIMENTAL.

It was found from these experiments that animals from which the left abdominal sympathetic trunk had been removed could walk well after a short interval, but exhibited the following peculiarities. When the animals were placed on the back both lower limbs were at first held extended, but after an interval the left limb gradually fell into a more flexed and abducted position than the right. The relaxation time of the left knee-jerk was found to be much shorter than that of the right; the relaxation and extension times were, on the operated side, approximately equal, and the whole movement was more quickly performed than on the right side. In addition, resistance to passive flexion and extension was greater on the normal side. These differences were more evident when the animal was placed under light anaesthesia; and when partially anaesthetized the animals were unable to support weight on the limb from which the sympathetic had been removed. The ability to maintain posture voluntarily in the operated limb, however, was retained, and only disappeared under anaesthesia. If the operation were performed on a decerebrate animal similar changes were observed; and further, the extension of the limbs peculiar to the decerebrate condition, although usually present, was not well maintained on the operated side.

In order to obtain independent testimony as to the accuracy of his conclusions, Dr. Royle called in the aid of an experienced neurologist, Dr. Campbell, who examined one of the goats operated on and fully confirmed Dr. Royle's observations and added several details to those mentioned above. He noted that the muscles of the operated limb were softer, the relative lack of tension being particularly noticeable on pressing the tendo Achillis against the bone; further, although the difference in the knee-jerks was as Dr. Royle had described, the least degree of excitement in the animal immediately caused them to become similar in character on the two sides. Some investigators have failed to verify Dr. Royle's results, but it is to be noted that they have experimented on small animals only, in which the changes are less readily detected than in goats; the results, however, have recently been corroborated by Kuntz and Kerper, who experimented on dogs.

THE FIRST CASE.

These experiments confirmed Dr. Royle in his opinion that the sympathetic system was responsible for the occurrence of spasticity, and he considered it justifiable to apply the operation in the human subject. An apparently suitable case came under his notice in September, 1923.

The patient, a man aged 30, had received a gunshot wound seven years before. The bullet, entering above the left ear caused extensive laceration in the region of the left central sulcus, and the wound extended across the middle line to the opposite hemisphere. The patient was unable to speak for three months, and unable to walk for two years, after the injury. On examination there was found to be right spastic hemiplegia affecting both limbs, with spasticity in the left leg and foot. On the right side the knee-jerk and ankle-jerk were exaggerated and there was patellar clonus; on the left side there were exaggerated ankle-jerk and ankle clonus. The Babinski reaction was present in both limbs. The patient could walk, but had great difficulty in controlling the right leg, and when bearing on it exhibited a coarse, uncontrollable tremor. He could walk forwards, but not laterally or backwards. Occasional tonic fits occurred, but were readily controlled. The genito-urinary system was normal, but the patient suffered from chronic constipation.

This patient exhibited a change for the better within six hours after the operation. While the right foot immediately fell into plantar flexion after being passively dorsiflexed, the return in the left foot was slow and gradual. The clonus on the right side became progressively less, while persisting on the left. There was an immediate improvement in voluntary movement; the range increased and muscular control was more effective; the patient was able to support himself on the right leg, an impossibility before the operation, and he could walk readily both backwards and forwards; there was also an improvement in balance, and the tremor affecting the right leg disappeared. The limbs showed an increase in size and power, and resistance to fatigue gradually became greater. The chronic constipation was permanently relieved.

This case has been subjected to criticism by Dr. Walsh and Dr. Adrian, and the following statement by Dr. Noble, honorary neurologist and psychiatrist to the Lewisham Hospital, is of interest in this connexion:

"I handed this patient over to several specialists who had much experience in Seale Hayne and other hospitals for functional nerve cases. He was given suggestion, re-education, and other forms of psychological treatment by competent physicians, but without success. He was married to a trained masseuse, who spent much time in re-educative methods before operation, but without result."

The effects of section of the sympathetic as exhibited in this patient, and in the laboratory experiments above described, were subsequently illustrated by some experiments of the late Professor John Irvine Hunter on the wing of the bird. A full account of Professor Hunter's researches was embodied, shortly after his death, in a series of lectures given at University College in January and February, 1925, by Professor Elliot Smith, and they appeared in our first volume for that year.

CONGENITAL SPASTIC PARAPLEGIA.

Dr. Royle considered that the results obtained in his first patient justified the adoption of a similar procedure in other patients suffering from spastic paralysis, among whom were a number of cases of congenital spastic paraplegia. This disease presents two main types—a rigid type and a choreic type. The rigid type falls into two groups: (*a*) in which the patient retains or has developed muscular control, and (*b*) in which no voluntary control is present. Muscular control, even when present, is always deficient and is limited by the difficulty experienced in moving against the rigidity of the antagonistic muscles; and conscious effort increases the rigidity. During rest evidence of rigidity is usually slight and the limbs may appear flaccid, while extensor and adductor spasm and other evidences of defective cortical control may make their appearance when an attempt is made to stand or walk. The range of passive movements in such patients is also limited in varying degrees. Increase in muscle tone is revealed in the abnormal character of the tendon reflexes, provided they are not masked by the rigidity. The relaxation phase is prolonged, and this may lead to the step-ladder phenomenon in the knee-jerk, in which successive contractions leave the leg in a more and more extended position. The Babinski reaction may be present or not. A feature which is present in all cases of spastic paralysis, and often well marked in congenital spastic paraplegia, is inadequacy of inhibition of muscular contraction. For example, a patient may be able to extend the knee, but finds a difficulty in relaxing the quadriceps afterwards. This may be regarded as evidence of a lack of control over the factor determining the maintenance of posture.

In the second group of cases referred to, in which muscular control is absent, the rigidity is part of a general condition in which the patient is subject to extensor spasms resembling those of the decerebrate animal. Postural tone may also be increased. On the other hand, a paralytic condition may be present, due, it may be, to an injury at birth resulting in a more or less complete physiological block.

The choreic type of the disease is characterized by persistent choreiform movements when the patient attempts to move, and in certain emotional states. An increase in postural tone may be present or not, and there may be increased reflex activity when the patient is at rest. There is, however, a rigidity imposed by the patient himself on his limbs, in order, apparently, to minimize the effect of the choreiform movements and that he may maintain his equilibrium on standing.

RESULTS OF OPERATION.

Dr. Royle reports the effect of sympathetic ramisection in twenty-six consecutive cases of spastic paraplegia, complete histories of which are given in the original paper. The operation was in all cases carried out on both lower limbs. The cases were of the rigid type, except one of the choreic type. The accompanying table summarizes the details.

As regards walking, there was a diminution of the disability in all patients except one, who was able to walk before the operation. Sixteen were unable to walk alone, and of these, fourteen learnt to walk within six months. In some cases the improvement was remarkable; thus, one patient, who could only walk with the aid of crutches, was able to play tennis one year after the operation, and a child exhibiting extensor and adductor spasms on attempting to stand could walk without assistance at the end of twelve months. Another notable effect of the operation is relief from the necessity for mechanical support; and ability to walk increasing distances without fatigue is a constant post-operative result. The improvement in walking is necessarily relative, for a patient who has had spastic paraplegia for a number of years cannot be expected to lose all trace of the disease. On the other hand, if the operation is done before contracture sets in, a child may acquire a gait which differs but little from the normal.

All the patients exhibited changes which can only be ascribed to altered tone. The rigidity of the limbs was invariably diminished and resistance to passive and active movement usually disappeared. Both the limitation of range and the resistance to movement in these cases of spastic paraplegia are always to a certain extent structural, and a gradual improvement is observed over and above that directly due to the operation. The excitability of the knee-jerk and of ankle clonus was diminished in the majority of cases. In a few instances the relaxation time remained prolonged, but in all cases it was lessened by the operation. It should be remarked that the complete removal of the sympathetic nerves to a limb does not diminish a patient's ability to maintain a posture voluntarily, and it has been observed in children after ramisection that extensor and adductor spasm may reappear when they are being examined by strangers; this is apparently due to cortical influence set in activity by emotion.

The faculty of balance or increased facility in balance is an invariable immediate post-operative effect, and accounts for the rapidity with which these patients learn to walk. It must be ascribed to an alteration in tone without sensory loss, and the greater power of inhibition which appears after removal of the sympathetic is an expression of the same change.

Almost every patient reported increased facility in performing active movements, a result which is directly due to the operation, since the gain in the range of active movement occurred immediately after it. Physical education, however, effects further improvement, and the improvement may continue for years.

Another important acquisition is the power of inhibition. In one patient, for instance, extension of the knee in the recumbent posture could not be inhibited even when the flexion was assisted by gravity, whereas after the operation the patient could immediately relax the contracted muscle. It is hardly necessary to point out that the presence of deformity and contracture, more especially as affecting the hamstring and calf muscles, militates against a complete result in sympathetic ramisection. Structural changes of this kind need to be dealt with surgically before the full effect of ramisection can become apparent. Further, it should be clearly understood that sympathetic ramisection is not advocated as a cure for spastic paralysis; it merely removes a factor which interferes with the normal physical education of the individual. The essential treatment of spastic paralysis is education of the central nervous system: the muscles themselves do not usually require attention; indeed, their treatment with massage and electricity only tends to stimulate the sensory end-organs, and this inevitably leads to an increase in tone.

SPASTIC CHOREA.

Spastic paralysis complicated by chorea or athetosis was formerly regarded by the author as unsuited for operation by sympathetic ramisection. The following case (No. 26 in the table) illustrates what may be expected in certain circumstances.

The patient, a female aged 19, was unable to walk or stand, and could sit only when supported. Choreiform movements affected all four limbs and the face and tongue; the limbs were under-developed through disuse; the knee-jerks were exaggerated and indicated an increase in tone by the prolonged relaxation

Table showing the Effect of Sympathetic Ramisection in Twenty-six Consecutive Cases of Spastic Paraplegia:

	Before Operation.							After Operation.						
Case No.	Age.	Able to Sit Up.	Able to Stand Alone.	Able to Walk Alone.	Able to Walk with Support.	Able to Balance on one Limb.	Was Patient Constipated?	Mentality.	Standing.	Walking.	Balance on one Lower Limb.	Ease in Performing Active Movements.	Constipation.	Mental Condition.	Time in Months Since Operation.

Explanation of Signs Used in the Table.—In (1), (2), (3), (4), (5), and (6) the sign + signifies "Yes," the − sign "No." In (7) the + sign signifies normal mentality, the − sign signifies subnormal mentality, and the mark ? inoicates mainly a defect through lack of education. The + sign in (8), (9), (10), (11), and (12) indicates the degree of improvement after operation. In (13) it indicates a noticeable impro.ement.

period; the Babinski test was doubtful. After a bilateral sympathetic ramisection there was an immediate change for the better in tone in the limbs operated on. Six weeks after the operation the patient was able to stand, and a few days later commenced to walk. Eight months after the operation she could stand unsupported for at least ten minutes and could walk alone for a hundred yards. The choreic movements have disappeared from the lower limbs when the patient is not excited, and there is some improvement in the upper limbs also.

Other cases which have been operated on are too recent to merit report.

In the concluding part of his paper Dr. Royle deals with the physical education of the spastic paralytic.

"It must," he says, "be clearly understood that the operation of sympathetic ramisection is not advocated as a cure for spastic paralysis. . . . It merely removes a factor which has been interfering with the normal physical education of the individual, and the essential treatment of spastic paralysis is education of the central nervous system. . . . It is true, however, that the treatment of paralysis of any variety has a peripheral as well as a central aspect, but in spastic paralysis the muscles themselves usually do not need attention; indeed, treatment with massage and electricity only tends to stimulate the sensory end-organs in the muscles, and this inevitably leads to an increase in tone. . . .

"It is sometimes thought that the operation of sympathetic ramisection should confer full and normal use of the muscles immediately, but this is a misconception. We can no more expect the subject of a congenital spastic paralysis to walk immediately after operation than we can a newborn infant. The normal child takes a year or longer to acquire control over the lower limbs sufficient to enable it to walk, and a similar time must be allowed for the spastic child. . . . Even when movements can be performed voluntarily in the lower limbs, control of the various groups is imperfect and the first consideration in education is to establish group control.

"The minimizing of mental effort must next be aimed at. On account of the fact that the patient's muscles have always been opposed by the rigidity of their antagonistic muscles, his mental effort is exaggerated and this tends to the use of unnecessary muscles. This mental habit persists and must be counteracted by teaching inhibition in the groups whose contraction would render the given movement defective."

VASCULAR DISEASES AND THE SYMPATHETIC SYSTEM.

BY

H. A. HARRIS, M.B., B.S.

(Institute of Anatomy, University College, and University College Hospital.)

SIR W. I. DE C. WHEELER's[1] recent report on two cases of thrombo-angiitis obliterans calls attention to problems of great interest. It may be useful to give an account of what is being done by investigators working in the various departments of medical inquiry to interpret the significance of disease in the blood vessels and the part possibly played by the sympathetic nervous system in their causation. In his Oliver-Sharpey lectures Dale[2] gave an excellent summary of the history of our present knowledge,

with special reference to the capillary bed. After submitting Stricker's proof of the contractility of the capillaries, Mayer's proof of the nervous control of the capillaries by the sympathetic nervous system, and Hooker's proof of the nervous control even when the circulation is at a standstill, Dale gives a vivid account of the work of a long series of observers in relation to anaphylaxis and to histamine shock. He discusses the experiments of Ninian Bruce in relation to local vaso-dilator reflexes, and deals in detail with the work of the schools which have grown up around Krogh, Sir Thomas Lewis,[3] and himself. From the historical point of view two incidents may be added. In 1850 Alfred Smee[4] showed preparations of the capillaries of the brain, eye, muscle, and skin, injected with carmine size, and suggested that the variation in the quantity of blood in the capillaries influenced the position of the lens and so controlled accommodation. In 1860 Lionel Beale[5] depicted fine non-medullated nerves coursing with the capillaries in striped muscle. Beale's researches in this connexion deserve special mention, for it is only recently that van den Bergh, McNee, and F. C. Mann have called attention to his brilliant work on the liver. Lionel Beale was "an inarticulately verbose genius" and a protagonist of the Vitalist School, "whose scientific observations were largely ignored as a result of the brilliantly lucid dialectic of Thomas Henry Huxley."

Dale expresses surprise that Rouget's demonstration, in 1873, of the contractile cells which bound the capillary endothelium should have remained unnoticed until comparatively recent times. The Rouget cells are flat contractile stellate cells applied to the outside of the capillary endothelium and encircling the vessel by delicate protoplasmic processes. That these cells had been observed before is evident from the description given by Eberth and Iwanoff in 1868[6]:

> "As the capillaries become larger a delicate tunica adventitia is superadded, which . . . is formed of a delicate network of fine fibrils, composed of the processes of stellate cells lying directly on the vascular wall."

Mayer, Vimtrup, and Dale regard these cells as contractile, sympathetically innervated, and so controlling largely the quantity of blood in the capillary bed. Recently E. R. and E. L. Clark[7] have shown that in the tadpole the capillaries display two types of contraction—the one with a wavy contour of the contracting small capillaries, and the other with a general reduction in the calibre of the larger capillaries. These contractions of the capillary are seen in young capillaries before any Rouget cells are attached thereto. During contraction the capillary is separated from the Rouget cell by a space which can be seen in a profile view. Hence the tonicity of the capillary endothelium of the amphibian larva is independent of the presence of the adventitial cells of Rouget. This finding of the Clarks is of great interest, inasmuch as fifty years ago Roy and Graham Brown said that the capillaries were elastic and contractile in themselves. Florey and Carleton,[8] in a recent paper on the capillaries of the cat, state that they are in general agreement with this view, and that the presence of Rouget cells in sufficient numbers to account for the contraction is doubtful.

An entirely different approach to the question of the nervous control of the blood vessels may be seen in the anatomical school associated with Elliot Smith.[9] His description in 1895 of a branch of the external thoracic nerve supplying the axillary artery, in conjunction with the late Sir William Thorburn's interest in cervical rib, led Todd[10] to a study of the effect of nerve lesions on the arteries. The observations of Wood Jones[11] on the relation of the nerve trunks to the uppermost ribs had also directed particular attention to this problem. Most of this work centred around the endarteritis obliterans which is seen in certain cases of cervical rib. Buzzard,[12] in 1902, was the first to suggest a vascular causation of the trophic disturbances seen in cases of this condition. He stressed the absence of herpes and papillary symptoms in the upper limb, and so concluded that the trophic disturbances were due to a lesion of the first thoracic nerve between the junction of the anterior and posterior roots and its union with the eighth cervical nerve to form the lower trunk. He regarded the spinal nerve itself as the seat of the change. Todd suggested that the trophic lesions of cervical rib were due to a lesion of the sympathetic nerves which run from the first (and sometimes the second) thoracic ganglion to course over the cervical rib on the under side of the lowest trunk.

Numerous papers were published in relation to the vascular symptoms of cervical rib by Todd, Telford, Wood Jones, and others. In 1914 Todd and Kramer[13] surveyed the distribution of nerves to the arteries of the arm. They showed that the subclavian and axillary arteries differ from the other arteries of the arm in receiving a nerve supply direct from the sympathetic chain. All other arteries in the upper limb obtain their nerve supply from sympathetic filaments which have travelled along the spinal nerves and are distributed to the various blood vessels at irregular intervals. The distal and peripheral blood vessels, more particularly those of the hand, receive nerve filaments at more frequent intervals than do the proximal channels. The distribution of nerves to vessels thus corresponds roughly with the distribution of nerves to the muscles and skin. The process of the blood vessel affection appears to be a preliminary period of stimulation of the sympathetic vaso-constrictor fibres followed by a paralysis of the vaso-constrictor fibres with consequent changes in the vessel wall. In short, the trophic lesions are the result, not the cause, of the vascular lesion.

A considerable amount of experimental work has been done in a direction which closely reproduces the trophic lesions of cervical rib. Bechterew summarized the results in 1908, and particular mention must be made of some of the experiments. Lapinski cut the cervical sympathetic in rabbits and showed that the arteries of the ear presented endarteritis obliterans, fragmentation of the elastic coat, and hyperplasia of the tunica media. This was followed by a rapid patchy atrophy of the media. These results were obtained in only seven out of fourteen animals. Cehanoviĕ repeated these experiments, and demonstrated a lack of tone and a delay in the pulse wave in the arteries comparable to that seen in human arterial disease. Fraenkel cut the sciatic nerve in rabbits and dogs and obtained lesions which closely resembled those seen in the anterior tibial vessels in tabes. This was confirmed by Bervoetz. Cyzharz and Helbing repeated these experiments, but did not obtain the vascular changes in all cases. Subsequent to the operation certain rabbits exhibited trophic changes in the dorsum of the foot, and in these alone were found the typical pathological changes in the vessels.

Had the correlation between anatomy and physiology been sufficiently close these experiments would have been readily interpreted. Schiff,[14] in 1854, showed that, allowing an interval of ten days for degeneration, excision of the superior cervical ganglion and of the upper part of the cervical sympathetic trunk did not prevent the vaso-constriction which he was the first to observe in stimulating the great auricular nerve. So Schiff concluded that the vaso-constrictor fibres of the great auricular nerve arise from the spinal cord in the upper cervical region and pass outwards in the roots of the second and third cervical nerves, which send branches to the great auricular nerve. These experiments were not confirmed until over forty years later, when Morley Fletcher[15] repeated them, and showed that some of the sympathetic fibres which reach the ear do so by the ramus vertebralis of the ganglion stellatum, along the vertebral artery to the third cervical nerve, and thence by way of the great auricular. It now became obvious that the discrepancies in the results obtained in the vessels by section of the sciatic nerve were due to the fact that some of the sympathetic fibres reach the lower limb along the femoral artery. Thus in each case the vessels of the limb receive a dual supply of sympathetic fibres—first, from the nerve plexus on the aorta and large vessels, and secondly, from the mixed peripheral nerve.

One of the first clinical applications of this was seen in the work of Leriche, Policard,[16] and their associates. They showed that the mechanical stimulation of the periarterial sympathetic plexus led to vaso-constriction, and that removal of the plexus led to a favourable vaso-dilatation in cases of trophic disturbance. They showed that the reaction of the periarterial sympathetic network varies in degree,

being more marked in some animals, less in others. It is more evident in the brachial than in the axillary or subclavian arteries, more active in the femoral than in the iliac arteries, in the brachial even more than in the femoral. The operative procedure of Leriche has not been taken up with enthusiasm in this country. However, Shaw[17] states that periarterial sympathectomy has been successful in 75 per cent. of cases of causalgia in the clinics of Leriche and Platon. Langley[18] says periarterial sympathectomy in man, so far as it relieves peripheral vaso-constriction, in all probability does not do so by severing nerve fibres running with the arteries to the periphery. Stopford[19] has discussed the possible nerve mechanism in cases of causalgia, and is inclined to consider that the main factor is a reflex peripheral vaso-dilatation of the vessels.

Recently Woollard,[20] in the Institute of Anatomy, University College, London, has confirmed the view that the limb vessels are innervated proximally by nerves direct from the aortic plexus and distally by contributions from the adjacent mixed nerves. Medullated nerves are shown most abundantly on the peripheral vessels, and they end not only by collaterals on the vessels, but also in the adjacent tissues. Woollard suggests that this anatomical relationship may be the basis of the axon reflex. He confirmed the sympathetic innervation of the capillaries, and shows sensory nerve endings of medullated fibres on the large, medium, and small arteries.

The whole problem of a sympathetic afferent apparatus is still in doubt. Trotter[21] has put forward the view that all naked nerve endings register pain, and that pain is the primordial mode of sensation. From it the discriminative forms of sensibility have been differentiated by the progressive degree of insulation of the nerve fibre, which is indicated by the acquirement of a medullated sheath on the one hand and by a special type of nerve ending on the other. Both in the preparations of Kulchitsky[22] and in those of Woollard one is struck by the number of naked non-medullated fibres which wander out into the tissues to form "free" endings.

A different point of view has emerged from the work of Pavlov[23] and Orbeli.[24] Briefly one might say that the Leningrad school of physiology is gradually establishing the existence of the trophic fibres which were empirically postulated by the ancient surgeons. Orbeli regards the sympathetic as containing fibres which regulate the somatic sensory and motor nerves, and determine the amount of material used in each tissue in the body. This work, largely unpublished, cannot be discussed in detail at present. It is mentioned in particular to call attention to the tendency to extend the range of sympathetic innervation to all the tissues in the body.

A tremendous impetus to the study of the sympathetic system followed the revolutionary publications of N. D. Royle[25] and the late John Irvine Hunter.[26] It is not proposed to discuss their application of sympathectomy to spastic paraplegia and allied conditions, but to indicate one result of the revival of the interest in the sympathetic system. The surgery of this system is not new. Nearly all the early operations have been discarded. The value of the few that have survived is still equivocal; and many have produced either indifference or bitter opposition. In 1889 Alexander[27] of Edinburgh resected the superior cervical ganglion of both sides; in 1892 Jacksh[28] resected the vertebral plexus and cut the cord connecting the middle and inferior ganglion; in 1893 Bojdanik[29] performed bilateral resection of the middle cervical ganglion; and in 1895 Jaboulay[30] cut the sympathetic cord above and below the ganglion. All of these operations were done for epilepsy. Jaboulay performed sympathectomy for exophthalmic goitre in the same year, and Jonnesco[31] performed the operation for glaucoma in 1897. Ball[32] of St. Louis, in 1899, removed the superior cervical ganglion for optic nerve atrophy and for glaucoma.

One outcome of the work of Hunter and Royle has been the rapid application of sympathectomy to diseases of the vasomotor apparatus. Adson[33] of Rochester noticed that, following removal of the second, third, and fourth lumbar ganglia in a case of spastic paraplegia, striking and persistent vaso-dilatation occurred in the feet for a period of six weeks. The vaso-dilatation was uniform and uninterrupted, and the feet became hot and dry with suppression of visible sweating. Adson and Brown[34] have published a series of papers dealing with the peripheral vascular disturbances of the extremities. In Raynaud's disease periarterial stripping gives no relief, but combined with lumbar sympathectomy it does. Cervical sympathectomy also causes marked relief when performed alone. In cases of endarteritis obliterans stripping of the vessels, as opposed to the results of some other surgeons, has given no relief. The injection of a foreign protein (typhoid vaccine) has relieved the symptoms in 50 per cent. of the cases, but sympathectomy has not been tried owing to the wide distribution of the concomitant arterio-sclerosis. In thrombo-angiitis obliterans occasional relief from pain has been obtained by the intravenous injection of foreign protein and by Roentgen-ray irradiation of the spine. Lumbar sympathectomy combined with stripping of the external iliac arteries has given marked relief from pain, the condition of the limb has improved, and trophic ulcers have healed. The heat evolution of the limb has increased from 50 to 110 per cent. and the temperature of the limb has increased from 1.5° to 6.4° C. These measurements were made with Sheard's thermo-couple thermometer and foot calorimeter. The results of sympathectomy in erythromelalgia have not yet been ascertained, but medical treatment and surgical stripping of the vessels have not availed.

The work of the surgeons in the Mayo Clinic is interesting in that, first, the thermal response to the injection of a foreign protein gives a ready indication of the degree of suitability for operation in a given case of vascular disease, and that, secondly, the results of sympathectomy in Raynaud's disease and in thrombo-angiitis obliterans are remarkably promising even after an interval of six months. The pain of thrombo-angiitis obliterans is extreme, sleep is fitful, and the patient is rapidly reduced to a mental and physical wreck. Even if such an operation postpones amputation for a few months its performance seems to be justified.

A further dramatic application of the operation of lumbar sympathectomy was witnessed in the following case.

The patient, a woman, aged 34, whose limbs were crippled with a polyarthritis of the rheumatoid type, had failed to respond to medical treatment over a period of six years. The hands and feet were cold and moist with trophic changes in the skin and nails; the interphalangeal joints were all enlarged and there was typical spindle-shaped swelling of the middle and index fingers. There was 25 per cent. limitation of movement in the ankles, 30 per cent. in the wrists, 20 per cent. in the elbows, and 50 per cent. in the shoulders. Pain was a prominent symptom in the hands and feet. As a result of the hopeless condition of the patient bilateral lumbar sympathectomy was suggested by Dr. Rowntree[35] and performed by Dr. Adson. The heat emitted from the feet was increased by 100 per cent. and the temperature by 8° C. I saw the patient before and after operation. The feet became warm, dry, and pink; the trophic changes in the skin and nails were disappearing. Pain had disappeared entirely from the feet and there was a sense of warmth therein. The patient was able to walk several hundred yards within five weeks of the operation. She is a typist, and has requested bilateral cervical sympathectomy, but it was deemed well to wait for six months or a year.

The effect of the operation in this case is equivalent in some respects to a particularly persistent passive hyperaemia of Bier, and one of the treatments employed in the Mayo Clinic in trophic conditions of the hands and feet is the application of an electrically heated glove or sock such as is worn by our Royal Air Force pilots at high altitudes.

Whereas Adson had been a champion of the Hunter-Royle operation for selected cases of spastic paraplegia, the Chicago surgeons Kanavel and Davies have strongly denied its benefits. It is gratifying, therefore, to see Davies and Kanavel[36] adopting lumbar and cervical sympathectomy for cases of vascular disease. They report marked relief of the symptoms of Raynaud's disease after cervical sympathectomy, marked relief of erythromelalgia by lumbar sympathectomy, and complete failure to obtain relief in a case of thrombo-angiitis obliterans. Their conclusions differ from those of Adson and Brown in that the latter operate for thrombo-angiitis obliterans, but not for erythromelalgia. I am tempted to suggest that the case of erythromelalgia might have been an early case of thrombo-angiitis obliterans. The patient was a Russian

Jewish tailor, aged 35. It is true that the arteries of *both legs and feet were easily palpable in this case, but* the disease may be more marked on the venous side of the capillaries in the earlier stages and limited, like many cases of post-operative thrombosis, to the deep veins of the calf. *Pain is often more marked in the calf than in the* foot, and is a phenomenon of veins as well as of arteries.

Wheeler's[1] two cases, and the two cases simultaneously published by Smith and Patterson,[37] along with the fact *that Telford and Stopford*[38] *saw four cases in one year in* non-Jewish patients, suggest that great care is necessary for the accurate differential diagnosis of the various types of vascular disease of the extremities. It is not sufficient to say "*threatened gangrene*"—*nor, for that matter, is* "erythromelalgia" more than a symptom.

Stopford has mentioned that the clinical characters of *thrombo-angiitis obliterans* were first described by *von Winiwarter in 1879, long before Buerger*[39] published the standard description in 1924. It may be added that Cornil and Ranvier,[40] in 1860, described "Oblitération des artères par endarteritis et thrombose," and pointed out that a coagulum may precede arteritis as well as arteritis precede a coagulum. Mention must be made of Rabinowitz,[41] who recently claimed to have isolated a Gram-negative, rod-shaped, and beaded organism from a case of *thrombo-angiitis obliterans*, and to have produced by the bacillus the same lesion in the vessels of the ears and feet of rabbits as that which was present in the leg of the human. Parkes Weber's[42] description of thrombo-angiitis obliterans as non-syphilitic arteritis obliterans of Hebrews no longer holds good. The disease attacks non-Jewish people. It belongs to the group of new diseases such as trench fever, hog cholera, and encephalitis lethargica.

In surveying the field we see that histology, in the work of Smee, Beale, Stricker, and Rouget, has made its precocious contributions. Gross anatomy and clinical surgery have opened a new line of advance determined by the investigation of the trophic lesions of cervical rib and their sympathetic origin. Leriche, Hunter, and Royle have given direction to the newer purposive surgery of the sympathetic system. Dale, Krogh, and Lewis are pioneers of a physiological and clinical line of attack. The protagonists of physico-chemical mechanisms are forging ahead. The whole of the experimental field, particularly as regards the comparative morphology of the sympathetic system, the comparative pharmacology, and the minute and laborious histology, calls for investigators. The histological work of the late Professor Kulchitsky at University College, London, was one of the mainsprings of the work of the late John Irvine Hunter. The recent surgical work in America and Australia is promising. The Russian physiologists are extending our conception of the trophic nerves. The morbid anatomy of the blood vessels, as shown by the divers systems of classification of vascular disease in text-books, is still chaotic. The clinical observations on the vascular diseases of the limb are limited to a few enthusiastic workers. Now, if ever, is the time to write in each hospital ward the following quotation: "Laboratory guides are mostly artificial, are reliable only in some *instances, and are the handiwork of man; clinical* symptoms are the natural, infallible, unalterable expressions of definite states, and are the ways of God." In each laboratory and dissecting room the text should be: "When the interest flags, strive to become the hero in the oldest of all tragedies—a deduction destroyed by a fact."

INTRAVENOUS THERAPY.*

BY

HAROLD PRITCHARD, M.D., F.R.C.P.,

PHYSICIAN TO THE WEST LONDON HOSPITAL.

THIS method of treatment has a great many advocates—more, perhaps, on the Continent and in America than in this country—and a great many adverse critics. There are points for and against it, but I think it has now so far justified itself as to deserve a legitimate place in modern therapeutics. It seems better to put remedies intended to act on the blood stream itself, or on some distant organ only reached through the blood stream, directly into the veins, rather than into the stomach, where they must mix with the food and take their chance of *being modified by* the digestive juices, and finally be subject to the whim of the absorptive mechanism of the alimentary canal. On the other hand, remedies intended to act primarily upon the stomach or intestines are best put there through the mouth. The ease and apparent safety with which intravenous salvarsan injections can be administered has given a great impetus to the use of the intravenous route for purposes of treatment.

The following advantages have been claimed in favour of the intravenous route: that the dose is more precise; that irritation of the gastro-intestinal tract is avoided; that the drug is not altered or destroyed in the alimentary tract; and that drugs act more promptly when given intravenously. I propose to criticize these in detail.

Precision of Dosage.—A medical man prescribes a remedy with the idea of producing a given effect; he desires to give the exact dose which will produce that effect—*no* more and no less. The appropriate amount is arrived at by giving repeated fractional doses by the mouth, each being well below the full therapeutic dose; it is assumed to be the dose required by the patient in the circumstances which obtain at that moment. The fractional dose can be increased until the desired effect is obtained. It is not practical to give repeated fractional intravenous doses of a drug; *therefore the intravenous dose is more liable to* err. For example, strophanthin acts powerfully when given intravenously, and a number of deaths from its use in this way have been recorded. It must be admitted that it is more difficult to arrive at the right therapeutic dose by the intravenous method than by giving a drug orally.

Absence of Gastro-Intestinal Irritation.—A drug which directly irritates the gastro-intestinal mucosa might be expected to irritate also the intima of the veins. The word "irritation" is used somewhat loosely in this respect; what is really meant is that the drug causes disturbance during the process of excretion. This applies more particularly to

* Abstract of Presidential Address delivered before the West London Medico-Chirurgical Society.

the heavy metals. One of the worst cases of intestinal irritation I can remember was after the intravenous injection of a mercury preparation.

Stability of Drug.—Many drugs are readily absorbed, unchanged, through the alimentary tract—the iodides, for example. On the other hand, salts of iron and arsenic are only partially absorbed, for some of the dose given is recoverable from the faeces. Many of the gland extracts are destroyed in the alimentary canal—adronaline is rendered inert when given by the mouth.

Prompt Action.—There can be no question that drugs act more speedily when given intravenously in acute cases, where rapid action is a matter of urgency. In the treatment of more chronic conditions a therapeutic effect is obtained more slowly whichever route is used.

Technique of Intravenous Injection.

The injection must be given as far as possible painlessly; if pain is caused it becomes increasingly difficult to get the patient to submit to further treatment. The vein should be entered at the first attempt, and the injection must never be commenced until the vein is entered with certainty. There is some excuse for not being able to get into the vein, but none for putting the injection into the surrounding tissues, thus giving rise to an area of infiltration, causing pain and local thrombosis, and incidentally failing to achieve the object desired. The needle should have a flat bevel with no shoulder, and a sharp point; it should enter skin and vein with one smooth movement. Needles, as supplied commercially, always have a shoulder and a long thin point. The shoulder is a source of difficulty in getting through the skin, and with a drawn-out point it is difficult to avoid puncturing the further side of the vein. Moreover, with such a needle part of the lumen is apt to remain outside the lumen of the vein, causing leakage into the surrounding tissue.

If the site at the bend of the elbow is chosen, the arm should lie comfortably on, and partly buried in, a pillow with the elbow-joint fully extended. A tourniquet should never be used. With the hand an assistant should compress the upper arm sufficiently firmly to obstruct the venous return, the arterial pulse still being felt at the wrist. The vein can be brought into greater prominence by stroking the forearm upwards. It is not necessary that a vein should be seen, but it must be felt. The vein should be "fixed" by stretching the skin over it between the thumb and forefinger of the left hand. This stretching renders the skin that is stretched partially anaesthetic. The vein on the central side of the fixing point becomes bulbous, and if the needle is now inserted through the upper edge of this stretched area at an angle, it should accurately enter the vein above. On entering the vein the piston of the syringe is slightly withdrawn and on the first appearance of blood the compression is at once released, and the injection proceeded with. In a nicely adjusted injection a thrill can be felt by lightly palpating the vein just above the site of injection while the fluid is running.

The injection must be given slowly, the rate depending upon the degree of concentration of the fluid and its bulk. It should be remembered that remedies introduced by the intravenous route are rapidly brought into contact with vital organs, such as the heart and the central nervous system. Time should therefore be allowed for the blood stream to distribute them.

I do not think it matters where the injection is made. The veins at the bend of the elbow are usually chosen because here they are more accessible and less covered by fat, but the following may be taken: the internal saphenous vein, where it crosses the internal malleolus; the posterior ulnar vein; the radial vein; the femoral vein; the external jugular vein; and, in young infants, the superior longitudinal sinus, though the anterior fontanelle is usually taken; this is a simple and safe procedure if the middle line is strictly adhered to, and the needle inserted into the posterior angle of the fontanelle, for here the superior longitudinal sinus is nearest the skin.

BLOOD TRANSFUSION.

Blood transfusion is now recognized as a therapeutic measure of the first importance. The donor's blood can be used in the form of whole blood, defibrinated blood, or citrated blood. The one I favour most is the citrated blood method; the transfusion can be given more deliberately, and there is time for the blood to be carried from a distance, if for any reason the donor cannot come to the recipient. The objection to this method is that toxic effects follow the introduction of sodium citrate into the blood stream, and that when transfusion is given as a pre-operative measure oozing is more likely to take place. I argue that, if the right amount of citrate be used and no more, no toxic effects will follow, and the oozing will not be greater than with any other method. The strength I use is 10 c.cm. of a 2 per cent. solution of sodium citrate for every 100 c.cm. of blood. It should be arranged to add the citrate solution by fractions, each fraction being sufficient to prevent clotting of 100 c.cm. of blood. At the commencement of the second 100 c.cm. the requisite amount of citrate solution is added.

The defibrinated method has much to recommend it, but it is, I think, easier to introduce clots into the circulation by this than by the citrate method, for it is not always possible to be quite sure that the blood used is all defibrinated, even after filtering.

Technique.

The simpler the apparatus the better. I have now abandoned the various complicated forms in favour of the simple one on the lines of the ordinary tube and funnel with a glass window near the needle. The blood is allowed to run in by gravity, this force being quite sufficient. A fairly long tube should be used, a few coils being allowed to rest in a vessel of water kept a few degrees above blood heat. The injection should proceed slowly—about twenty minutes being taken to inject 500 c.cm. If the patient is restless and apprehensive the injection may be made easier by first giving 1/6 grain of morphine or heroin. The blood should be filtered through several layers of gauze after citration. Grouping should be carefully performed, and in choosing a donor it is important to take one of the homologous group and not the so-called "universal donor".—Group IV. Many members of this group are not quite negative to the other three groups, and I feel sure it is owing to this that many unpleasant symptoms arise—such as restlessness, dyspnoea, obscurations of vision, noises in the ears, difficulty of speech, fever, shivering, pain in the chest. I am much in favour of repeated small transfusions—say, 200 to 500 c.cm.—rather than one big one; they are especially useful in the chronic anaemias, and in arresting internal haemorrhages such as from a leaking gastric or duodenal ulcer.

Blood transfusion should never be undertaken lightly. The conditions in which it is indicated are many, and each case must be judged on its merits. It is especially valuable (1) in industrial surgery, where accidents have been accompanied by great loss of blood; (2) in sudden loss of blood from any other cause, such as a bleeding gastric or duodenal ulcer; (3) in any conditions of chronic anaemia where the blood state cannot be improved by other forms of treatment, especially in people around and past middle life—this group would include the toxaemic states, the anaemia here being secondary to the chronic intoxication; (4) as a pre-operative measure, where the red-cell count and haemoglobin estimation are definitely below normal. I deprecate giving a blood transfusion until a full and careful blood examination has been made. It is often indicated for operations on malignant growths where there is a secondary anaemia. In splenic anaemia, where the spleen is being removed, it is advisable to transfuse at the time of operation. I believe the main value of transfusion is due to the stimulus it gives to the blood-forming mechanism.

SALINE INFUSION.

The infusion of normal saline into the veins is a measure of very old standing, and until salvarsan injections were started, in 1909, it was the commonest form of intravenous treatment. When normal saline is injected intravenously the immediate effect is a rise in blood pressure and a fall in the specific gravity of the blood. This is followed in thirty minutes or so by a fall in pressure and a rise in specific gravity, the effect of osmosis, the excess of fluid introduced into the circulation being rapidly excreted by the kidneys and the skin. If circulatory failure is present, or the heart is acting very feebly, as in old people, this excess of fluid is apt to become lodged in the tissues, particularly in the lungs, thus rendering the patient's last condition worse than his first.

Hypertonic saline was introduced with the idea, of course, of attracting the fluid from the tissues into the vessels. The same physical laws, however, obtain with hypertonic saline as with normal saline; since the vessel wall is permeable to salts the condition which occurs with normal saline is rapidly brought about. It appears, therefore, that blood lost cannot be permanently replaced by a simple saline solution; the benefit obtained is too transient, and saline infusion, therefore, should be regarded simply as a temporary measure. It would seem that the fluid advocated by Bayliss (sodium chloride 2 grams, potassium chloride 0.05 gram, calcium chloride 0.05 gram, powdered gum acacia 5 grams, distilled water 100 c.cm.) is, when prepared exactly as he described, the best injection for loss of blood, where blood cannot readily be obtained. Blood, if it can be obtained, is, of course, better than gum saline. For gum saline to be effective there must be present a sufficient percentage of haemoglobin to carry on the process of oxygenation. Saline infusions, in

addition to their use for temporarily replacing blood lost, are of great value in treating the toxaemic states—uraemia, eclampsia, etc.—the patient being bled and then infused; though here again a better result is obtained by using blood.

INTRAVENOUS MEDICATION.

With regard to the introduction of remedies into the circulation I will confine my remarks to those of which I have personal experience.

Intravenous proteins I have used in the treatment of many disabilities—chiefly spasmodic asthma, infective arthritis, and chronic skin diseases, all conditions in which the nature of the infective agent has not been determined. I should say that about half the cases so treated have been benefited. The proteins used have been T.A.B. emulsion 100 to 500 million, *Bacillus coli* emulsion 100 million, *Staphylococcus aureus* 500 million, and Witte's peptone, 10 c.cm. of a 2 per cent. solution. The most marked reaction is ushered in by a shivering attack, followed by a rapid rise of temperature, with a corresponding increase in the pulse rate; the leucocyte count is raised; headache, malaise, and aches and pains in joints and limbs may be present. The reaction passes in the course of thirty-six hours, and is followed in a favourable case by improvement in the clinical condition. The injections should be repeated four times or so at intervals of seven to ten days. There appears to be a direct relation between the amount of reaction and the improvement obtained; for this reason T.A.B. injection proves the most efficacious. Vaccines when given intravenously act more potently than when given under the skin. I believe that too much has been made hitherto of the specific nature of a vaccine, and that careful preparation is more important than any other single factor.

With regard to intravenous injection of antitoxic serums I have had a very limited experience. Candidly I am rather afraid of this method. I tried it during the war in cases of acute sepsis. I was never sure that the benefit obtained was commensurate with the reaction and upset to which it generally gave rise, and I am still not convinced that intravenous serum has any advantages over the intramuscular and subcutaneous routes.

Of the other remedies I have used intravenously I may mention in particular mercury perchloride. So high an opinion have I formed of this drug that I think every clinician who may be called upon to treat acute cases should keep a solution of it prepared; a suitable dose—1/64, 1/32, or 1/16 grain—could then readily be chosen; the strength I suggest is 1/16 grain of mercury perchloride in 8 c.cm. of normal saline. I have used it chiefly in the following conditions: (1) pneumonia, lobar and lobular; (2) acute staphylococcal infections; (3) chorea, subacute rheumatism; (4) chronic infective arthritis of undetermined origin; (5) encephalitis lethargica.

The treatment of lobar pneumonia has hitherto chiefly been symptomatic. I have from time to time tried various serums, and also typed vaccine, but have not been struck by the results. Quite empirically I started, about eighteen months ago, systematically injecting cases of lobar pneumonia, at whatever stage they came under observation, with 1/32 grain of mercury perchloride. Most of those I have so far treated have responded favourably. Such figures as I have point to an association between the injection of the mercury perchloride and the favourable turn which these cases have taken. I have had quite marked results in bronchopneumonia also, especially in children. Infections by *Staphylococcus aureus* appear to be consistently benefited by injections of perchloride. It is of value in the more chronic infections, such as boils, and in the acute cases, such as acute infective osteomyelitis.

It is a matter of common experience that acute rheumatism under treatment usually clears up within a short time, but the subacute forms, particularly in children, with possible endocarditis and manifestations of chorea, hang fire; the treatment of these patients is unsatisfactory. I have injected a number of these cases with mercury perchloride. Some cases of chorea I have treated have shown improvement in the movements and in the general health, but the fever has continued; in the end the fever too has disappeared. I realize that here, as with pneumonia, one is on very shifty ground, for these things may happen by treating with rest alone. It is only, however, by taking a large number of cases treated with mercury, and comparing them with a similar number treated without, that it is possible to arrive at conclusions. My impression, so far, is distinctly favourable to the mercury treatment.

Cases of chronic infective arthritis, where there is no septic focus which can be determined after careful search, have been improved by intravenous injections of mercury perchloride 1/32 grain every three days. I have also used in such cases sodium salicylate 15 grains with sodium iodide 15 grains in 20 c.cm. of distilled water.

Among many other drugs which have been used intravenously iron cacodylate in half-grain doses every other day is a very efficient way of raising the haemoglobin content. Tylcalcin (a calcium salt of salicylic acid) is a useful form of salicylate for intravenous injection in acute and subacute rheumatism. Acriflavine (40 c.cm. of 1 in 1,000 solution in normal saline) should certainly be tried in septicaemia. Magnesium sulphate (20 c.cm. of a 10 per cent. solution) is of use in controlling the convulsions in eclampsia and uraemia by virtue of its sedative action on voluntary muscle; it also promotes urinary secretion when given intravenously. Urotropine acts more powerfully when given intravenously.

How do these intravenous remedies act? On this point I must at once confess ignorance. It is inconceivable that 1/32 grain of mercury perchloride, for example, can have any antiseptic action when diluted in the blood stream. Perhaps the reaction may be simply that which is associated with putting a foreign substance in the blood stream.

The intravenous route has much to recommend it. By whatever channel drugs are given, they must ultimately reach the circulating blood. Therefore it would appear to be only logical to put them straight into the blood stream. But intravenous medication demands careful handling, and, in using it, one must err on the side of caution.

THE TREATMENT OF RODENT ULCER BY TRICHLORACETIC ACID.

BY

H. LESLIE-ROBERTS, M.D.,

LATELY LECTURER IN DISEASES OF THE SKIN IN THE UNIVERSITY OF LIVERPOOL; CONSULTING DERMATOLOGIST TO THE LIVERPOOL ROYAL INFIRMARY.

BEFORE the days of radium and *x* rays surgeons were often compelled to treat malignant growth by means of caustics. The need of some chemical which would destroy the growth was felt when the growth occurred on the eyelids or the inner canthus of the eyes, or on the side of the nose, or in the nostril, where complete removal of the growth would entail great deformity.

Various caustics were employed, such as solid "potassa fusa," zinc chloride, acid nitrate of mercury, Vienna or arsenical paste, antimony, and pyrogallic acid. The use of these chemical agents gradually dropped into oblivion, since their use was accompanied, not only by severe pain, but not infrequently by accelerated metabolism, whereby a quiet growing tumour was converted into a growth of a more malignant type.

We know why these caustics fell into disrepute; it was because of their dangerous tendency to set up oedema, which was followed by rapid destruction of cells in the superficial parts of the tumours with absorption of toxic products and accelerated growth in the deeper parts. It may be laid down as a general rule that a caustic which increases the water contents of a malignant cell should always be avoided.

The superiority of trichloracetic acid in the treatment of rodent ulcer lies in the fact that its action leads to complete coagulation of the cell-contents. The compounds

formed between the acid and the cell contents are non-hydrophil, and therefore do not tend to draw lymph out of the capillaries. In consequence of this property the acid converts the neoplasm into a solid block of dead tissue, which is gradually thrust out by the undergrowth of the healthy living cell of the epidermis. I need not enter here into the biochemical relations of this acid.*

Briefly stated, there are three chloracetic acids, according to the number of hydrogen atoms in the acetic acid molecule replaced by chlorine. The trichloracetic acid possesses in highest measure the characters of the group. Among the most remarkable of these properties is the power of dissolving both water, and oils and fats; trichloracetic acid is both hydrophil and oleophil. Its capacity for dissolving all the simple proteins is shown by its solvent action on solid tissues; skin, the various organs of the body, dead meat, and vegetable matter are reduced in time to a thin almost invisible membrane of connective tissues. Keratin itself is insoluble. Owing to its very powerful oleophil properties, trichloracetic acid is able to penetrate through living tissue. The time taken to penetrate varies in different regions of the body surface. Furthermore, the severity and duration of the reactions of the cutaneous tissues vary with the region occupied by those tissues. The skin covering the sides of the fingers and toes may be described as non-reactive, any reaction that may appear being ephemeral. The acid penetrates rapidly through the normal flexor surfaces of the limbs, and the reactions slowly evolve in the course of many weeks. Penetration through the extensor surfaces is slower, and the reactions are of shorter duration.

Trichloracetic acid finds its highest utility in the treatment of rodent ulcer and all the benign forms of epithelial neoplasms—for example, milium tricho-epitheliomata, fibro-sebaceous moles, and hairy pigmented moles. Rosacea, which may be regarded as a seborrhoeic epithelial neoplastic disease, will yield to a 20 per cent. solution of this acid, which, however, is inferior to sulphur and salicylic acid in the treatment of the disease. Corns and warts yield more slowly, since penetration is difficult, but trichloracetic acid is probably our best remedy for these common benign neoplasms, the only safe alternative being electrolysis.

Method of Application in Rodent Ulcer and Benign Epithelial Growths.

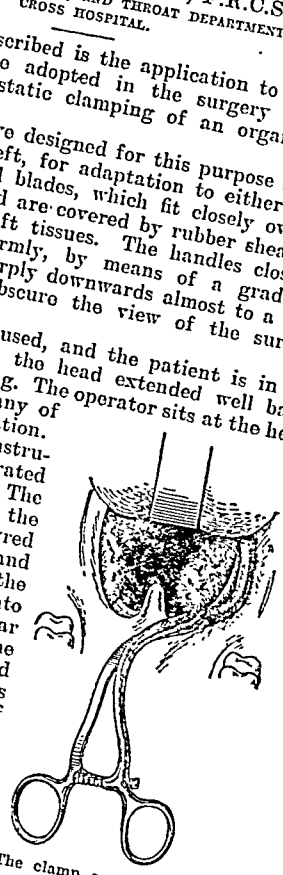
Trichloracetic acid is a crystalline substance which dissolves very readily in water. Three drachms of the acid require from 19 to 20 minims of water to form a concentrated liquid acid holding a small quantity of water in solution. A solid crystal should never be applied, for the sudden melting may result in extension of the acid far beyond the area intended. For safety's sake the adjacent skin should be protected by a smear of vaseline, but this is not always necessary. The applicator should be a glass rod, 1 to 2 mm. in diameter according to the size of the area to be covered. Cotton-wool need not be used. The acid should be applied until the skin is definitely white over the whole area, and this should not exceed three-quarters of an inch. Penetration is accompanied by a smart stinging sensation. When penetration is effected the part is well bathed with water till all the stinging has ceased. In rodent ulcer and solid growths I generally allow three minutes before neutralizing with water. Usually from this time not the slightest discomfort is experienced by the patient; very occasionally a burning sensation has persisted for some hours. For the next twenty-four hours no soap or water should be allowed to come in contact with the treated skin. The dead tissue is to be allowed to separate spontaneously. The time taken for separation of the dry eschar is about twenty-two days. No ointments should be applied. After separation of the primary eschar a minute secondary crust sometimes forms and separates in the course of a few days—usually after four weeks from the application.

* A reader interested in the subject will find a fuller account of these relations in the *British Journal of Dermatology and Syphilis*, August, September, and October, 1925.

A HAEMOSTATIC CLAMP AS AN AID IN DISSECTION OF TONSILS.

BY

L. GRAHAM BROWN, M.D., F.R.C.S.,



ASSISTANT SURGEON, EAR, NOSE, AND THROAT DEPARTMENT, CHARING CROSS HOSPITAL.

THE method to be described is the application to tonsillectomy of the principle adopted in the surgery of other regions of the haemostatic clamping of an organ before incision.

The instrument I have designed for this purpose is made in pairs, a right and left, for adaptation to either tonsil. It has curved, flattened blades, which fit closely over the pillars of the fauces, and are covered by rubber sheaths to avoid injury to these soft tissues. The handles close the blades gently, though firmly, by means of a graduated ratchet, and are bent sharply downwards almost to a right angle in order not to obscure the view of the surgeon during his manipulations.

The Boyle-Davis gag is used, and the patient is in the usual dorsal position, with the head extended well backwards over a rounded sandbag. The operator sits at the head of the table, and employs any of the usual methods of illumination.

The application of the instrument is easy, and is well illustrated by the accompanying figure. The chief points to observe are: the lower blade is carefully manœuvred underneath the soft palate and deep to the posterior pillar; the upper blade is then brought into position upon the anterior pillar and its extension to the side of the tongue; the tonsil is next gripped with a pair of tenaculum forceps and pulled through the blades of the clamp until the latter are in the correct position for closure.

The clamp applied to right tonsil.

The sliding action of the upper on the lower blade of the clamp as it closes itself helps in this protrusion of the tonsil from its bed, and hence the operator is chiefly concerned with the accurate adjustment of the blades to the pillars, taking care that they are applied as far backwards from the free margins of the pillars as space will allow. All hold on the instrument can now be dispensed with and the actual dissection of the tonsil begun.

The following claims are made for the use of this haemostatic clamp:

1. The instrument can be applied in almost all cases, the comparatively few failures depending, not on the size or nature of the tonsil to be removed, but on the width of the pillars of the fauces.
2. During removal of the tonsil there is practically no bleeding.
3. The actual dissection is rendered quick, easy, and complete, owing to the absence of haemorrhage and the fact that the tissue between the tonsil and its bed is squeezed into a thin line between the closed blades from which the tonsil readily separates.
4. No bruising of the soft tissues need occur.
5. The method is specially applicable in the case of small, fibrous, or adherent tonsils, and causes a minimum of destruction to the tissues of the pillars and tonsillar bed.
6. The main vessels of supply to the tonsil can usually be readily seen during the dissection, picked up, and ligated if necessary.
7. The after-effects of operation are no greater than those of any other method of dissection.
8. Deep anaesthesia is not such an important factor to the surgeon as when dissection is carried out without the aid of the clamp.
9. With a smaller sized instrument children can be similarly operated upon in place of the guillotine method.

The instrument can be seen at Messrs. Allen and Hanburys (48, Wigmore Street, W.1), and is supplied by them.

LATE RESULTS OF CHRONIC GASTRIC ULCER TREATED MEDICALLY.

BY

L. FORMAN, M.D., M.R.C.P.

IN order to throw light on the late results in cases of chronic gastric ulcer treated by medical methods without operation, the records of patients admitted to the wards of Guy's Hospital from 1914 to 1922 have been examined.

The difficulty of proving the presence of a gastric ulcer is often considerable—the only absolute proof is afforded by handling the viscus at operation or on the *post-mortem* table. The next best confirmation of the diagnosis is the positive result of an *x*-ray examination; failing this, we are reduced to ordinary clinical methods, which, however, are not infallible.

The cases selected from the reports were those in which *x*-ray examination revealed definite evidence of ulceration, usually by the presence of a crater. Four cases were used where a laparotomy had been performed, but no operative treatment on the stomach had been undertaken owing either to the position of the ulcer or to the adhesions around it; in three of these cases the ulcer was high up on the lesser curvature.

During the eight years covered, 79 cases were found which gave *x*-ray evidence of ulceration, and were followed up. The smallness of this number compared with the total admitted with the diagnosis of gastric ulcer is to be explained by the fact that in the reports of some of the cases no mention was made of the *x*-ray findings, and in others no *x*-ray examination was made—for example, in haematemesis. By studying cases with positive *x*-ray findings the position of the ulcer could be defined, and an attempt made to ascertain results of treatment relative to the position.

Each patient was sent a printed form on which questions as to the subsequent history of the abdominal condition were set. Where possible an interview was arranged, when the answers could be supplemented and the stomach screened. From the 79 cases so selected 57 replies were received; 16 could not be used owing mainly to operative intervention. There remained, therefore, 41 cases, and 32 interviews were obtained and the stomachs screened. The results were arranged in the following groups:

A. Absolute freedom from symptoms since leaving the hospital —9 cases (22 per cent.).

B. Marked improvement had resulted and persisted as a result of hospital treatment in 9 (20 per cent.). This group also included those who were very much better and who had a negative *x*-ray examination in 1925.

C. The number *in statu quo ante* was 19.

D. The symptoms had become worse in 4.

The percentage of A and B together was 42; of C and D together 57.

These percentages may be compared with the late results found by Dr. Conybeare in 39 cases of gastric ulcer treated surgically at Guy's.[1]

Medical Cases.		*Surgical Cases.*	
Group A 22%	... 42%	Group A 38.0%	... 58%
Group B 20%		Group B 20.0%	
Group C	... 57%	Group C 17.5%	... 40%
Group D		Group D 22.5%	

The results, analysed in regard to position, are as follows:

Ulcers in the Cardiac Third of the Stomach.—Six cases were obtained; of these, 4 were in Group A and 2 in Group B.

Ulcers in the Middle Third of the Stomach.—Number of cases 27. In Group A there were 2 cases (7 per cent.); in Group B 3 cases (11 per cent.), in Group C 17 cases (63 per cent.); and in Group D 3 cases (11 per cent.).

Ulcers in the Pyloric Third of the Stomach.—Number of cases 10. In Group A there were 3 cases (30 per cent.); in Group B 4 cases (40 per cent.); in Group C 2 cases (20 per cent.); and in Group D 1 case (10 per cent.)

It has been stated that the result of medical treatment varies with the duration of the symptoms, and presumably the chronicity of the ulcer. In this series the length of history of the cases was as follows:

Cardiac Cases.—Those in Group A had a history of 3 years, 10 years, 3 months, and 2 weeks respectively; those in Group B of 2 years.

Mid-Gastric Cases.—Of the two cases in Group A, one had a history of 11 years, the other of 6 months. Of those in Group B there was a history of 9 years, 12 years, and 12 years respectively. Of the Group C cases symptoms had been present for 20 years in one case; for 17, 11, 9, 7, and 6 years respectively in five cases; for 5 years each in four cases; for 2 years in one, 1½ years in one, 1 year in each of five cases; for 2 months in one, and for 1 week in one. Of the three cases in Group D, one had a history of 9 years, one of 5 years, and the third of 1 year.

Ulcer in the Pyloric Third of the Stomach.—Symptoms had been present in the three cases in Group A for 15, 7, and 4 years respectively; in the four cases in Group B for 15, 14, 9, and 3 years respectively; in the three cases in Groups C and D for 15 years in one, and for 1 year each in the other two.

The above does not show any constant relationship between the duration of the condition before treatment and the ultimate result. Thus in the mid-gastric group, seven cases unrelieved by treatment had histories of one year or less. Krohn,[3] discussing the results of medical treatment in 200 cases of gastric ulcer, came to a similar conclusion.

Relation of Results and After-treatment.

The patients were practically all of the artisan class, in whom dieting and the regular taking of medicines is likely to prove irksome if not impossible. It was found that no dieting was practised save during the bouts of pain, when meat, etc., was avoided, and bismuth taken. This absence of prolonged after-treatment may help to explain the failures.

Conclusions.

1. Very optimistic claims are made from time to time for the results of medical treatment of ulcers. It is interesting to note the results given at roughly ten years' interval: Joslin[2] in 1899 gave 40 per cent. well at the end of five years, and in 1914, 39 per cent. Krohn[3] in 1924 gave 48 per cent. in patients over 40 years of age. These authors include gastric and duodenal ulcers in their figures. The 48 per cent. well or very much better of this series would agree with the above. The treatment of gastric ulceration has changed in the last thirty years, but this change is not reflected in my figures.

2. The impression that the chances of successful treatment of an ulcer with a long history are poorer than in one of short duration does not receive support in this series.

3. The cardiac cases, although very small in number, give a good result for medical treatment.

My thanks are due to Dr. Poulton for his help and advice, and to the physicians of Guy's Hospital for giving me access to the reports.

MEDICAL, SURGICAL, OBSTETRICAL.

RUPTURE OF THE RECTUS ABDOMINIS MUSCLE.

TRAUMATIC rupture of the rectus abdominis is a rare condition, though one easily diagnosed. It has been recorded as occurring in tetanus, and there is a specimen in the museum of the Royal College of Surgeons in which the muscle has been completely torn across as a result of a tetanic spasm. Severance of a few fibres of the rectus muscle is probably not uncommon, and after labour a peculiar tumour, really a fibroma, occasionally occurs, which is traumatic in origin.

A woman, aged 35, an acrobat, was admitted to the Leeds General Infirmary on January 23rd, 1927. Ten days before admission, while performing a trick, she had experienced a sudden severe pain in the abdomen which compelled her to give up her performance that night, which was a Saturday. The following week she managed to perform some of her less arduous tricks, but on the Saturday of that week she again hurt herself and had to give up her work and to seek admission to the infirmary. There was marked tenderness over the rectus abdominis muscle just below and to the outer side of the umbilicus and slight swelling. Above this a distinct gap could be felt occupying about half the transverse extent of the muscle. This became visible on the patient raising her head. Operation was recommended and carried out. An incision was made over the injured area and the rectus sheath exposed. This was opened and the muscle was found torn through about half of its extent. The gap, which was three-quarters of an inch wide, was filled with blood clot

This was cleared out and the divided muscle united with stout catgut applied as mattress sutures. The patient made an uninterrupted recovery. She was advised not to do acrobatics for at least three months.

Leeds. P. J. Mom, M.B., F.R.C.S.

RUPTURE OF THE RECTUS ABDOMINIS MUSCLE SIMULATING APPENDICITIS.

RUPTURE of the rectus abdominis muscle by indirect violence appears to be a condition of relatively rare occurrence, and is not mentioned in any of the standard textbooks as a lesion to be considered in the differential diagnosis of appendicitis.

A woman, aged 48, was admitted to Northampton General Hospital on February 8th, 1927. Six weeks previously, while stretching up to take a jar from a shelf, she felt a sharp pain in the *right iliac region*. The pain was present for three days, but there were no other symptoms, and she was able to do her housework. One week before admission, while walking about the house, she again felt the pain and went to bed. The pain became a constant ache with occasional sharp twinges, located at first in the suprapubic region and later in the right iliac fossa. During the week she also complained of loss of appetite and was feverish at night, sweating frequently. She had no cough, nausea, or vomiting, but was constipated.

On admission t[illegible] 3°, and the pulse 96. The abdomen presente[illegible]ne lower half of the right rectus muscle an[illegible]s, with its maximum one inch above and [illegible] point. No tumour was palpable. The heart and chest were normal. A diagnosis of subacute appendicitis was made, and the abdomen opened by a right paramedial incision. The rectus sheath was blood-stained, and on opening it the middle third of the muscle was found to be ruptured about 1½ inches below the umbilicus. Between the fragments was a blood clot which appeared to be partially organized. The muscle itself was dark red. On opening the peritoneum the appendix was found to be normal in every way. The ends of the ruptured muscle were approximated and the wound closed. Apart from the extrusion of a catgut suture the patient made an uneventful recovery and was discharged with a firm scar in sixteen days.

Of twenty-five recorded cases of rupture of the rectus abdominis muscle twenty-three occurred during influenza, one in pneumonia, one from coughing, cause not stated, and one from an effort in jumping.[1] The presence of muscular lesions in influenza and of a special predilection for the rectus abdominis, resulting in some cases in rupture, was made clear by Abrahams, Hallows, and French in 1919.[2] They described the muscle as haemorrhagic and pulpy, and thus distinct from the *pallid* appearance seen in other acute fevers such as typhoid. The lesions occurred chiefly in the very severe cases of influenza.

Where there is a definite infective lesion the occurrence of muscle rupture from slight degrees of violence is easy to explain, but in the case here recorded the rupture presumably took place six weeks before admission and at a time when the patient was *in good health*. The recurrence of symptoms five weeks later is difficult to explain, as she can give no history of a second strain.

I am indebted to Mr. Holman, F.R.C.S., for permission to publish this case.

Northampton. C. R. McCASH, M.B., Ch.B.

PULMONARY EMBOLISM FOLLOWING CHILDBIRTH—RECOVERY.

IT may be of interest to add the following report of a case of pulmonary embolism to those recently published in the JOURNAL.

A primipara, aged 33, was delivered of a boy weighing 8 lb. in May, 1926; labour was somewhat lengthy, but not unduly so considering her age; otherwise it was normal in every way.

I was present at the birth, and her general condition was excellent. I was sent for three days later and found her very cyanosed, with a small pulse of 160, the temperature 100.5°, respirations 45. She told me that she had been *quite well until* an hour or so previously, when she felt a sudden severe pain in the left side of the chest, with difficulty in breathing. It was an effort for her to talk, and she was coughing up frothy blood-stained sputum.

The only physical sign I could find was a small area of dullness in the left upper lobe; everything else was normal.

Oxygen was given through a closely fitting mask, and on two occasions a quarter of a grain of morphine hypodermically for the pain. She was very ill for fourteen days; she then gradually recovered, and was up within four weeks. She is expecting her second child in June.

Reports of Societies.

EXPERIMENTAL ENDOMETRIAL GRAFTS.

AT a meeting of the North of England Obstetrical and Gynaecological Society on April 1st, at the Medical Institution, Liverpool, with the President, Professor FLETCHER SHAW, in the chair, Dr. J. W. A. HUNTER read a paper entitled "Some observations on experimental endometrial grafts."

Dr. Hunter said that though workers appeared to be satisfied when they had demonstrated the possibility of heterotopic endometrial growth, yet no one had as yet reproduced in animals a condition comparable with tarry ovarian cysts in women. In his research he had used some forty rabbits; the transplants were mostly autogenous, but a few were heterogeneous. The general reaction obtained was the growth of a multilocular cyst lined by columnar epithelium which was non-infiltrating; stromal proliferation only occurred in the papillary buds. From rabbits killed on the third and tenth days respectively after grafting two methods of cyst formation were found. The epithelium dipped down into the graft to form a cyst, or it covered the graft and lined the undersurface of the layer of fibrin which sealed in the graft. It was also noticeable in these experiments that while the columnar epithelium was scanty in the depths of the graft, it always covered the outer surface and grew along the lines of tissue junction. The stroma in the early stages was engorged. In order to test the effect of vascularity of the site of grafting, some transplants were placed in the liver and some in an avascular part of the abdominal wall in the same rabbit. The former showed considerable proliferation of endometrium with preservation of the racemose gland arrangement but surrounded by a definite capsule, whilst the latter showed a scanty growth of epithelium of a low activity. Even after 290 days a very active growth was found in the liver, whereas it was not so exuberant in the ovary. In another animal, after 388 days the general reaction was obvious, and after 760 days very small cystadenomata were found in atrophic ovaries. As a test of the influence of ovarian hormone grafts were introduced into the ovaries, and both the ovaries, containing corpora lutea, from another animal were transplanted into the abdominal wall. Fifty-four days later very large cystadenomata were found with adhesions to many adjacent organs; these showed large thin-walled cysts without invasion of surrounding structures. This result could only be obtained when the grafted ovaries from another animal contained corpora lutea. In an experiment in which the grafts were placed in the abdominal cavity of a male rabbit it was found thirty days later that there was no trace of the columnar epithelium, but the gland spaces remained. An attempt to confirm the "serosal" theory by the implantation of pieces of peritoneum and subperitoneal tissue produced a negative result, although there was an active growth of the mesothelial tissues. In one case in which grafts were placed in the ovary and the ovary was then transplanted into the abdominal wall definite endometriosis with invasion was produced. Dr. Hunter concluded from this series of observations that fragments of endometrium when grafted into any organ could grow. He considered that the factors which controlled growth of the stroma and endometrium were not the same, and that there was a selective action of the hormone of the corpus luteum controlling endometrial growth, more especially its epithelial portion. The experiments showed that whereas implanted endometrium could continue to grow for an almost unlimited time, it did not, in normal circumstances, become invasive. In the one instance in which there was an abnormal factor present (transplantation of the ovary which was the sito of the graft) the typical picture of endometriosis was obtained. This rather led to the view that for the production of the human picture, one factor, either the endometrium or the invaded tissue, must be abnormal.

Dr. S. B. HEAD asked whether the time in the oestral cycle at which the endometrium was taken for grafting made any difference to its capacity for growth.

Professor BLAIR BELL commended Dr. Hunter's research, and said that such investigations would advance knowledge of an interesting subject. He showed a specimen which indicated that it was possible experimentally to secure, not only an endometrial tumour by implantation, but also, during pregnancy at any rate, to produce a "shower" of glandular implants almost entirely over the whole peritoneal surface of the abdominal cavity.

The PRESIDENT emphasized the importance of comparing results obtained by experimental methods of this kind with clinical experience.

Dr. HUNTER, replying, stated that in his experience the time in the oestral cycle at which material was obtained for grafting made no difference to its capacity for growth.

Unusual Congenital Abnormalities.

Professor D. DOUGAL reported a case of unusual malformation of the broad ligament. He said that a married nullipara, aged 45, had complained of a blood-stained discharge of twelve months' duration; a severe haemorrhage had occurred two months before she was seen. On examination the uterus was found enlarged. The cervix was much thickened, very hard, and stretched, and there was a good deal of bleeding on examination. On opening the abdomen it was found that the uterus contained a number of fibroids, including one in the cervical canal. The main interest, however, lay in the malformation of the left appendage. The left ovary lay with its inner pole close to the internal abdominal ring, and running from it into the inguinal canal was a thick muscular cord, about one-eighth of an inch of this being visible between the ovary and the ring. The ovary was normal in appearance. The left Fallopian tube was somewhat small and terminated on the outer side of the ovary more than two inches from the uterus; the fimbriated end was fully developed. The kidney and ureter were completely absent on this side. Running from the ovary towards the uterus was a fold of peritoneum in the outer part of which could be made out a fibro-muscular structure, which tapered to a point and terminated about one inch from the uterus. The peritoneal fold joined the uterus about the junction of the body and cervix. The right ovary and tube were apparently normal, and were attached to the uterus at a much higher level than the peritoneal fold on the opposite side. The uterus itself was much distorted by the presence of fibroids, but Professor Dougal thought it might be assumed to be of the unicornuate type, the left horn being completely absent. The upper part of the left Müllerian duct formed the Fallopian tube, and there the further development of this structure had ceased. The Wolffian structures on this side were evidently absent. The position of the ovary at the internal abdominal ring was interesting, as the fibro-muscular cord attaching it to the ring presumably represented the ovarian and round ligaments. As the Müllerian duct on this side had not grown inwards to fuse with its fellow of the opposite side, the gubernaculum had drawn the ovary straight downwards to the inguinal ring. The malformation was undoubtedly rare, and he had only been able to find a record of one somewhat similar case, which was reported by Bonnaire and Durante in 1912.

Professor Dougal described also a case of unilateral duplication of the ureter with one ectopic opening. The patient, aged 24, unmarried, had complained of deficient control over micturition, which had been present practically since birth. She was able to pass urine in the ordinary way, but in addition was wet both night and day. She always wore a diaper and used three in the twenty-four hours—one during the night and two during the day. The leakage was noticeably worse in cold weather. She was well developed and highly educated, and was acutely conscious of her disability. On inspecting the vulva carefully Professor Dougal thought that he could observe urine welling up from the vagina. He therefore decided that the condition was more than a mere weakness of the sphincteric control of the bladder, and admitted her to a nursing home for further investigation under anaesthesia. During this examination he found that the urine escaped periodically from a small opening in the vestibule just below the urethral opening, and a little to the right of the middle line. It was a simple matter to demonstrate that the urine coming from this opening did not pass through the bladder, and it was therefore evident that the condition was one of ectopic ureteral opening. Mr. Wilson Hey found that there were two ureteral openings normally situated in the bladder, and that both were acting normally. In addition there was a second ureter on the right side, and this one had an ectopic opening on the vestibule. Sodium bromide was injected into the right ureter on the left side, but only a small quantity could be passed in and there appeared to be some partial obstruction in the upper part. This salt was also injected into the ectopic opening of the right ureter, and passed freely up to the kidney pelvis. Professor Dougal said that there were evidently two pelves and two ureters on the right side; one of these ureters had an ectopic opening from the vestibule. The lower part of the ectopic ureter was sacculated, as was well seen in the radiogram. This abnormality was obviously important clinically, but it was also interesting from an embryological point of view, as the ectopic ureteral opening in this case was situated at the point where Gärtner's duct was usually supposed to terminate.

Professor BLAIR BELL called attention to the fact that true uterus unicornis was very rare. Most cases so described had been, in reality, cases of uterus bicornis in which one horn was poorly developed. Two other points of interest were demonstrable in Professor Dougal's specimen. The ovarian ligament on the side on which the uterine horn was not developed ran straight to the inguinal ring, indicating the truth of views emphasized by the speaker many years previously, that the round ligament and the ovarian ligament were one structure, and together represented the gubernaculum. The second point of interest was that, although the Fallopian tube as a whole was not formed, the fimbriated extremity was present—a matter of common observation in many cases of malformation of the parts, and one which bore out Keith's contention of the origin of the fimbriated extremity from the pronephros.

Clinical Demonstrations.

Professor BLAIR BELL described a specimen and sections of carcinoma of the cervix with pregnancy. The patient was a 12-para, aged 36, and was twenty-two weeks pregnant when seen. Panhysterectomy with bilateral salpingo-oöphorectomy and appendicectomy was performed, and recovery was uneventful. Subsequently she was treated by injections of lead colloid. Professor Blair Bell said that cancer of the cervix associated with pregnancy was decidedly rare, occurring on an average once in about every 10,000 cases of pregnancy.

He then showed a case of primary adenocarcinoma of the Fallopian tubes in a primipara, aged 45. She had complained of pain in the back and hypogastrium, and a yellow inoffensive discharge for twelve months; there was frequency of micturition, and the patient became exhausted on the slightest exertion. The uterus was thought to be enlarged, irregular and immobile. A large swelling was felt through the anterior fornix, evidently pressing on the bladder. A hard mass was felt on either side of the uterus. Panhysterectomy with bilateral salpingo-oöphorectomy was performed, but was extremely difficult, owing to the density of the adhesions and the presence of bilateral ovarian cysts, which appeared to burrow deeply in the loose tissues of the pelvis. Subsequently a small vesico-vaginal fistula was found and easily repaired. Professor Blair Bell said that primary carcinoma of the Fallopian tube was rare, less than 150 cases being reported in the literature. It was probable that the condition occurred with greater frequency but that the cases were not recorded. He had had three cases, but the other two had not previously been reported, although a section from one of these was illustrated in the last edition of his *Principles of Gynaecology*.

He also showed three cases of Krukenberg tumour, one associated with pregnancy. The first patient was a nulliparous married woman, aged 35, who complained of a bearing-down pain in the hypogastrium, with frequency of micturition almost amounting to incontinence. On examination a large tumour, mostly in the right iliac fossa but extending in the hypogastrium to the umbilicus, was felt.

The cervix was immobile, and the uterus could not be separated from the tumour. Following operation the patient died from heart failure. The second patient, a 7-para, aged 42, complained of vomiting for eighteen months, and pain in the epigastrium relieved by the vomiting. She also had obstinate constipation, loss of weight, weakness, and haemorrhoids. On examination the tumour was discovered in the epigastrium, and was thought to involve the liver. There was dullness in the flanks and free fluid in the abdomen. At laparotomy a primary carcinoma of the pylorus was discovered adherent to the liver, in which there were secondary nodules. There were nodules on the peritoneum. The right ovary was the size of a large coco-nut; the left ovary was smaller. Subtotal hysterectomy with bilateral salpingo-oöphorectomy was performed. Thereafter she had a course of six injections of lead colloid, but death occurred at the end of eight and a half months. The third patient, a 5-para, aged 32, complained of diarrhoea for two years and a painless lump in the right iliac fossa, which had gradually increased in size for four months. Just before she was seen she had had a severe pain in the right side, accompanied by vomiting and diarrhoea. There had been loss of weight. On examination the uterus was found to be about four months pregnant, and there was a solid tumour to the right of it, which extended into the pouch of Douglas. The uterus itself was mobile. Supravaginal hysterectomy with double salpingo-oöphorectomy was performed. The right ovary was enlarged to the size of a foetal head, and was adherent to the rectum. The left ovary did not appear to be affected. A cicatricial area at the pyloric end of the stomach was detected. Subsequently x rays showed malignant disease at the pylorus. The patient commenced a course of lead injections, but was lost sight of later. Professor Blair Bell said that these tumours, originally described by Krukenberg as primary sarcoma carcinomatodes of the ovary, were now invariably regarded as secondary to gastric, or possibly intestinal, carcinoma.

Dr. BURNS mentioned a case of carcinoma of the cervix complicating a sixteen weeks' pregnancy for which he performed Wertheim's pelvic dissection, and later applied radium to an early recurrence in the vaginal vault with a satisfactory result. Miss IVENS said that she did not consider primary carcinoma of the Fallopian tube as a very malignant condition, and quoted two cases of her own in support of this view. Dr. W. W. KING asked how long the patients with Krukenberg's tumour had lived after operation, as from his experience of three cases the average time was only about three months. Professor BLAIR BELL, in reply, said that he considered primary carcinoma of the Fallopian tube on a par as regards malignancy with adenocarcinoma of the body of the uterus; for a long time the disease remained enclosed within the tube. While this was so, extension or metastasis was rare, but once the tube wall was penetrated extension was rapid. As the Krukenberg tumours were always secondary to disease elsewhere, removal of them alone, without further treatment, must be followed in a few months by the death of the patient.

Mrs. DOBBIN CRAWFORD reported a case of double vaginal cyst arising from Gärtner's duct. The patient, a multipara, aged 52, suffered discomfort and pain from a swelling in the vulva caused by one of two vaginal cysts. This was the size of a golf ball and occupied the lower part of the right antero-lateral vaginal wall, ending at the vestibule about half an inch behind the urethra. The second cyst was above the first; it was smaller and oval, and passed up towards the right fornix. The cysts did not appear to communicate with each other. Each was readily shelled out from beneath the vaginal mucous membrane, but in the deeper layers was attached by dense fibrous tissue. The lining membrane was smooth throughout and there was no sign of infection. A section showed that the cyst was lined by epithelium which was cubical in most parts, but here and there a fold in the cyst wall was lined by columnar cells; these cells had possibly been protected by the fold from pressure and so had undergone no flattening. Outside the epithelium a layer of connective tissue was to be seen surrounded by muscle. Several cases on record of distension of Gärtner's duct were mentioned, in particular that reported by Amand Routh in 1894, in which a parovarian cyst was in communication with a vaginal cyst, which latter opened by a very small orifice at the base of the vestibule about half an inch behind and to the right of the urethra, quite distinct from Skene's tubules.

Professor ERNEST GLYNN described a case of idiopathic dilatation of the urinary bladder in a woman aged 48; trabeculae were well developed and a small sacculus was present. There was also a moderate amount of bilateral hydronephrosis. The uterus was normal. He had performed necropsies on two similar cases in men. He wondered how far such a condition might be produced by habit. On the other hand, he pointed out that idiopathic hypertrophy of the bladder with hydronephrosis was described in children. He himself had seen two cases *post mortem*, both males, aged 12 and 16 respectively. Dr. J. E. GEMMELL described two cases he had seen. No cause could be assigned for the first, but the second was certainly due to a "habit"; the patient, finding it very difficult to leave her work, had accustomed herself to going all day without emptying her bladder. Dr. W. W. KING also quoted two cases due to habit—the one in a cinema pianist, and the other in a chronic alcoholic who had prolonged periods of unconsciousness. Professor GLYNN, in reply, quoted a similar case in a policeman who was on point duty for long hours at a time.

FRACTURE OF THE PATELLA.

AT a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland on March 25th, Sir WILLIAM I. DE COURCY WHEELER in the chair, Mr. W. PEARSON showed a child, aged 10, on whom he had recently operated for fractured patella.

Mr. Pearson said that the child had climbed up on to a mangle and had fallen to the floor; she had not been able to get up. She was taken to hospital, and the knee-joint was found to be very distended, obviously with blood; owing to this distension it had been very difficult to make a diagnosis. A skiagram, however, showed that the patella had been fractured. Six days after admission Mr. Pearson had operated, and had found a typical transverse fracture of the patella. The operation had now been performed three months, and the child could run about quite well. Mr. Pearson said that this form of fracture of the patella was a very common injury in adult life, but it was believed to be an injury which never occurred in children, and practically never in adolescence. He thought it probable that the reason for the rarity of the injury in children was the fact that the knee extensor was very elastic at that age.

Sir WILLIAM WHEELER said that there was very little in the literature about fractures of the patella in children; but it was stated that they were unknown before the age of 10, were very rare up to the age of 20, and were almost confined to later life.

Mr. A. CHANCE referred to the good mobility of the knee obtained in Mr. Pearson's case. He added that it was essential to get back the full range of flexion, for anything short of full range involved a recurrence of patellar strain with possible repetition of the fracture.

Mr. PEARSON, replying, agreed with Mr. Chance that a fracture of the patella might recur; he proposed to keep his patient under observation until he had obtained full range of flexion. He thought that fracture of one patella predisposed to fracture of the other.

Psoas Abscess due to Tuberculous Kidney.

Mr. SETON PRINGLE showed a specimen of a tuberculous kidney associated with the formation of a psoas abscess.

A woman, aged 32, was admitted to hospital complaining of a large swelling in the right side of the abdomen which had grown slowly and without pain, and of a second swelling in the upper inner aspect of the right thigh. On examination the clinical features of a typical psoas abscess presented, but, in addition, a hard nodular tumour could be felt in the right hypochondrium, immediately underneath the anterior abdominal wall. This tumour gave the impression of being a pathological kidney, displaced forwards by the development of the abscess. No evidence of disease could be detected in the spine, which was perfectly flexible. The urine on examination was quite normal, and the cystoscope revealed a normal left ureter and a normal bladder, except for very slight scarring at the site of the right ureteric opening. The opening itself could not be identified after prolonged

search, and certainly was not functioning. There was no evidence of any inflammatory process in the neighbourhood. An x-ray examination of the right renal region and spine was negative. The psoas abscess was aspirated in the upper part of the thigh and 32 ounces evacuated. The right renal region was explored through an antero-lateral oblique incision, and the kidney, which had been completely infiltrated by tuberculosis, was removed. In doing this the abscess cavity was opened and a communication between it and a caseous cavity in the substance of the kidney was easily established.

Sir WILLIAM WHEELER said that this was a very rare specimen. He had never heard of a psoas abscess which was directly due to a tuberculous kidney, as in this case. Mr. DENIS KENNEDY thought that the ureter became affected first, and the disease developed behind it. Mr. C. J. MACAULEY regarded this case as being analogous to cases in which a large gland was found in the neck, with a caseous abscess at the bottom of it. He suggested that the absence of previous bladder symptoms could be accounted for by the early closure of the ureter.

JAMES MACKENZIE INSTITUTE.

Acidosis.

THE concluding lecture of the spring course at the James Mackenzie Institute for Clinical Research, St. Andrews, was delivered by Dr. G. MATTHEW FYFE, his subject being laboratory observations on acidosis. After remarking on how little was really known regarding the biochemistry of acidosis, largely on account of the complicated changes which occur, the lecturer pointed out that even in the most intense manifestations of the disease the reaction of the blood remained practically constant. The mechanism by which this constancy was maintained was an intricate one depending upon two essential processes—the presence of buffer substances and the excretion of acid bodies—interference with which resulted in the appearance of the syndrome clinically termed acidosis. The actions of the bicarbonates and the phosphates, which together constituted what was termed the alkaline reserve of the blood (a sustained diminution of which gave rise to the symptoms of acidosis), were described, and the significance in the laboratory diagnosis of acidosis, of observations on the amount of bicarbonate and CO_2 in the blood and of CO_2 in alveolar air, was emphasized, as was the information sometimes derived from comparative estimations of the reactions of the blood and of the urine. Little information could be derived from the buffer effect of amphoteric proteins in acidosis. Regarding the cells of the body two similar neutrality regulating processes were described—that of the "chloride shift" and that of the alterations which occur in the strength of haemoglobin as an acid. Their mechanism, however, could not be estimated in exact terms, but nevertheless it was thought that the cells along with proteins constituted a line of defence second to that of the alkaline reserve. There was described an accessory mechanism, controlled by the kidneys, wherein a considerable amount of ammonia derived from the faulty deaminization of proteins was used to neutralize abnormal acids, so as to prevent loss of the fixed alkalis of the blood and tissues. The criteria of acidosis then would be: (1) Excretion of acid urine; (2) decrease in the bicarbonates of the blood, with consequent decrease of its CO_2 combining power; (3) decrease in the CO_2 tension of alveolar air; (4) alteration in the ammonia coefficient of urine; (5) excretion of ketone bodies.

An opportunity was taken at this point to define acidosis and ketosis as different phenomena, the former being a perversion of physiological processes, the latter being a pathological process accompanied by acidosis. Acidosis was defined as an interference with the neutrality regulating processes of the body, with a consequent deficiency in its powers to deal with the acid substances produced in metabolism. The concluding part of the paper was concerned with laboratory methods of diagnosing acidosis, with methods of estimating the acidity of the urine, acid excretion by the kidney, sodium bicarbonate in plasma, CO_2 in alveolar air, ammonia and ketone bodies in urine were described. By the simple expedient, however, of administering sodium bicarbonate by mouth and of testing the reaction of the urine, the physician had at his command probably the most practicable test at present available.

Reviews.

THE THEORY OF PERCEPTION.

SIR J. H. PARSONS'S *Introduction to the Theory of Perception*[1] is one of the series of volumes forming the Cambridge Psychological Library. Psychology is largely studied by introspective and other methods which are not very amenable to strict scientific discipline, and the study of perception, which may be said to form a connecting link between consciousness and simpler nerve processes, brings it into touch with the biological relations of the organisms and affords a mode of approach that is open to direct observation and experiment.

The author introduces the subject by a statement in general terms of the nature, genesis, and mechanism of perception. This is followed in subsequent parts of the work by a more detailed discussion of the various aspects of the problem, more especially in connexion with vision, the author's own special study. The simplest example of the mechanism is to be found in the unicellular organisms; here no differentiation of sensory receptors exists, nor any differentiated paths for incoming and outgoing impulses. There are no co-ordinating centres, but the whole body reacts in the mass. Consciousness, if it exists at all, is a mere vague awareness, associated with a feeling of pleasantness or unpleasantness according to the nature of the stimulus; and the response is limited to a simple withdrawal or approach, depending on the biological requirements of the animal. To this fundamental form of sensibility the name protopathic has been applied, in accordance with Head's nomenclature; it is manifestly of great importance for the preservation of the individual in the lowest types, and its existence can be recognized, according to the author, even in the highest forms of sensibility. Mounting a step higher, definitely localized receptors of stimuli are met with and impulses are transmitted through localized paths, forming the reflex arcs with their central intercommunications. Notwithstanding the increased complexity involved in these changes, it is possible to conceive, at least theoretically, that the sensibility retains, in the main, its protopathic character.

The next stage discloses a marked advance depending on the diversity of the stimuli impinging on the organism. Receptors become differentiated, introducing different modalities of sensation, such as vision and audition, and the impulses received in consciousness cease to be homogeneous. It is at this stage, apparently, that perception arises, the term denoting consciousness, with discrimination added to the mere feeling of pleasantness and unpleasantness. There arises a consciousness that certain groups or patterns of impulses among the aggregate of impulses received have a special biological significance, and these perceptual patterns, stereotyped by habit, become prepotent over concomitant impulses. Sensibility, therefore, in this stage, while still retaining a latent protopathic character, acquires discriminating or, as is said, epicritic features, and the mechanism becomes dual. A further important modification arises from the predominance of one or more of the sensory modalities; in some animals the sense of smell, in others that of sight, and these differences have a psychological bearing depending on the particular mode of life of the animal. The relatively complex mechanism described forms the basis of instinct; in its purest form the consciousness of perceptual patterns is held to act by inducing some definite emotional tone, and this exerts an influence on the motor response which is normal to the given stimulus. A good example of instinctive response is seen in the first flight of birds. The mechanism is transmitted hereditarily, and on the receipt of the appropriate stimulus flight occurs without any preliminary tentative rehearsals or deduction from previous experience. A still higher type of epicritic sensibility has its anatomical basis in the association-tracts of the cortex, which also subserve what the author, introducing a new term, calls the syncritic integration of perceptual patterns, such

[1] *An Introduction to the Theory of Perception.* By Sir John Herbert Parsons, C.B.E., D.Sc., F.R.C.S., F.R.S. Cambridge Psychological Library. London: Cambridge University Press. 1927. (Roy. 8vo, pp. viii + 254; 71 figures. 18s. net.)

integrated patterns becoming manifest in consciousness and active in conceptual thought. It would appear that in consciousness on this the plane of intelligence, the integrated perceptual patterns act less as inducing mere emotional tone than as independent internal stimuli.

Such, in general terms, is the thesis which the author develops with a wealth of illustration, citation, and exemplification that at times leads to some degree of obscuration of the thesis itself, though its complexity may render this unavoidable. The subject is subsequently treated in detail in three directions: a discussion of the principal sensations of the fundamental perceptions, and especially those of space and movement, and of the evidences derived from the study of comparative anatomy, the main part of the discussion centring round the mechanism of vision, this heading are considered the dual mechanism of vision, the appreciation of form and contour; colour vision; the sensatory response and its duration in the epicritic form; visual induction, excitation and conduction; and the comparative anatomy of the eye and development of the visual paths. A point of particular interest is mentioned bearing on the trichromatic theory of colour vision. It has been shown that the response to a momentary flash of light is not a momentary sensation but a wave of sensation which may be graphically represented by a curve; and further, that the sensation-curves of the fundamental colours develop with unequal rapidity, so that their summits occupy different positions and can be separately distinguished. By fatiguing the retina with monochromatic light a modification can be observed in the sensation-curves, corresponding in position to the spectral colour used, and it is found that, whatever the colour employed, modification occurs in the curves of red, green, and violet only—a strong confirmation of the view that these are the fundamental colours and the others merely combinations of them.

The author disclaims any attempt to have written an exhaustive treatise on perception; his design has been to gather together some prolegomena or preliminary remarks on the subject and to formulate a working hypothesis. A study of the book will convince the reader that it must be a formidable superstructure that requires so substantial a foundation.

SIR GEORGE NEWMAN'S ESSAYS.

UNDER the title *Interpreters of Nature*[1] Sir GEORGE NEWMAN has now collected nine essays and addresses previously published privately, or in some instances in journals not readily accessible. They are not perhaps what some might anticipate from a chief medical officer of the Ministry of Health; but those who are familiar with his reports on medical education and allied subjects will not be surprised. These essays are mainly devoted to medical biography and history, as is shown by the titles "A century of medicine at Padua," "Thomas Sydenham," "Hermann Boerhaave," "John Hunter," "Louis Pasteur," "John Keats," and "William Osler, a physician of two continents." Written in a very pleasant and withal scholarly style, with many allusions, poetical and literary, they analyse the character and achievements of his heroes, who so well interpreted what they had observed in their various capacities. The "Century of medicine at Padua," appropriately written in 1922, the octocentenary of that celebrated university, is dedicated to the medical students of St. Bartholomew's Hospital, on the staff of which William Harvey served as physician from 1609 to 1643. It is just the companion that a medical visitor to Padua should take with him to create the atmosphere of its ancient influence and fame. The account of Sydenham, "the reformer of English medicine," first appeared in the year of the tercentenary of his birth (1624-1924), and the oration "On the disciples of Boerhaave in Edinburgh" was delivered last June at the bicentenary of the Medical Faculty in the University of Edinburgh. The sketch of Sir William Osler is excellent in its affectionate insight, and it is a matter for no small regret that he has not given, as he so well could, a companion appreciation of Sir William's "brother" regius, Sir Clifford Allbutt. There is, indeed, a likeness between these essays and those of Sir William Osler, not only in manner, but in one instance at least in their subject matter, for they both, though with a quarter of a century's interval, deal with the life of John Keats, Sir George's tribute being laid on the poet's grave on the centenary of his death.

This charming volume, fit companion for a holiday, closes with two addresses delivered in similar circumstances—annual congresses of the Royal Sanitary Institute—"Modern interpreters: fifty years' progress in public health" and "Future interpreters: everyman in preventive medicine," which remind the reader of medicine's ideal, the prevention rather than the cure of disease.

[1] *Interpreters of Nature.* By Sir George Newman, K.C.B., M.D. Hon. D.C.L. (Oxon.). London: Faber and Gwyer, Ltd. 1927. (5½ × 8½, pp. viii + 256. 12s. 6d.)

THE NATURE OF THE INTRA-OCULAR FLUIDS.

THE third of the Monograph Supplements issued by the *British Journal of Ophthalmology*[2] bears the above title and is the work of Dr. W. STEWART DUKE-ELDER. It incorporates work done for the Sir Francis Laking prize of St. George's Hospital Medical School for the two years 1926-27 in the biochemical department of the hospital.

The book is divided into an experimental and a theoretical section, and a very complete bibliography adds materially to its value. The author concludes that "the nature of the formation and circulation of the aqueous humour as at present classically accepted and taught is wrong; the aqueous is neither a secretion nor, in the accepted sense, a transudate from the blood; it is a dialysate from the capillary plasma, the essential dialysing membrane being the capillary walls; under normal conditions, while an interchange due to metabolic activity constantly occurs, and an internal thermal current exists, the aqueous humour does not circulate actively through the eye, but is in equilibrium with the capillary blood; at the same time, constantly occurring changes of pressure, induced by muscular movements, etc., superimpose upon it secondarily a minimal and intermittent circulation."

No abstract can do justice to the value of this most important piece of original work. In our opinion Dr. Duke-Elder makes out an overwhelmingly strong case for his conclusions; if these are accepted—and we do not see how any who read this monograph can come to any other—it will mean that "many of the problems of ophthalmology will require revision," especially the problems of cataract and glaucoma.

With regard to the secretory theory, which of late years has been the most favoured in this country, it is here shown that the only evidence in its favour is purely anatomical. The ciliary body is not always present. "If it be accepted as a gland, then it must be admitted that it shows no activity as a gland, but merely allows the aqueous to diffuse through its cells passively; that is, it must be admitted that it secretes nothing, for the intra-ocular fluids are in thermo-dynamical equilibrium with the capillary blood, and in their passage through the epithelial cells no work of any kind—chemical, hydrostatic, osmotic, or electrostatic—is done."

Many years ago old Robert Burton, Democritus Junior, took the slight liberty of putting the word "addictus" in the classical quotation that adorns the title-page of this monograph into the plural. He went on as follows: "They will approve of naught but what they first invent themselves, no interpretation good but what their infallible spirit dictates; none shall be *in secundis*, no not *in tertiis*, but they and their followers; *caedem Scripturarum faciunt ad materiam suam*, saith Tertullian: they make a slaughter of scriptures, and turn it as a nose of wax to their own ends."

We owe it to Duke-Elder—who has approached this problem with physico-chemical experiment, "the most legitimate way in that it involves the introduction of few extraneous influences, and is the least equivocal in the interpretation of its results"—that we can in the future be on the right track in investigating many of the

[2] *The Nature of the Intra-Ocular Fluids.* By W. Stewart Duke-Elder. *British Journal of Ophthalmology* (Monograph Supplement III). London: George Pulman and Sons, Ltd. 1927. (Roy. 8vo, pp. 140; 5 figures. 7s. 6d.)

biochemical problems of ophthalmology; and for ourselves, as we had the pleasure of reading this monograph in manuscript and in proof before its issue to the world, we can honestly say, in the quaint phraseology of Burton, that we will come, if necessary, "*e faucibus Erebi*, from the chops of hell," in support of it. R. R. J.

CLINICAL STUDY OF MENTAL DISORDERS.

THE presidential address on *The Clinical Study of Mental Disorders*,[4] delivered at the eighty-fifth annual meeting of the Royal Medico-Psychological Association by Lieut.-Colonel J. R. LORD, C.B.E., F.R.C.P., and reported in our issue of July 17th, 1926, has now been reprinted from the *Journal of Mental Science* and published as a separate volume.

In this address the author has directed his attention principally to the probable future of psychiatry, envisaging its possibilities and the lines of progress it should follow if real advancement is to continue. Lamenting the divorce that has taken place between general medicine and psychiatry, for which he holds both blameworthy, Colonel Lord believes that a nearer approach will bring great gain to both. It is in general medicine that he would find the roots of the science and art of psychiatry. In illustration of this he points to the close relationship to general medicine which exists in such disordered mental functions as the pain, anxiety, and mental fatigue of all acute illnesses, the delirium of fevers, the mental confusion of uraemia, acute alcoholism and toxaemia, the gloom and irritability of alimentary disturbances, the spes phthisica, the coma of diabetes, the hebetude of myxoedema, etc.

He recounts also the great number of patients who first seek relief from private practitioners or general hospitals for mental disorders clothed in the garb of physical disease, and deplores that in many cases this is not recognized until too late. It is in the field of general practice that Colonel Lord considers the greatest advance will be made. "Here the roots of the evil will be located and eradicated and its growth to maturity prevented by methods of prophylaxis. Every general practitioner will then be a psychiatrist. . . . To build up this wider psychiatry which has its roots in general practice, there is urgent necessity for more mental clinics in connexion with the medical schools for teaching purposes, and the next essential is to ensure and maintain a greater efficiency of clinical psychiatry in the mental hospitals. The mental hospitals will then take up their rightful position as in the case of other special hospitals—that is, as adjuncts to general hospitals and work in close relationship with them."

Colonel Lord's address is one which all who are concerned with the prophylaxis and treatment of mental disorder should make a point of reading.

THE MEDICAL ANNUAL, 1927.

The Medical Annual[5] for 1927 follows worthily in the wake of its predecessors, and presents a comprehensive review of medical progress during the past year. Though no new discovery of outstanding importance is recorded, various improvements in treatment illustrate the present tendency of physicians to strive to impart order and direction to modern therapeutics.

The subject-matter of the *Annual* retains the form of a dictionary, and such an arrangement does not readily lend itself to analytical review; nevertheless, numerous points of practical utility can readily be observed. Many of the papers, perhaps of necessity, seem to err on the side of brevity. Fuller details of symptomatology and treatment would have been valuable in some instances; but here criticism ends. The *Annual* is full of interest and of practical help.

The names of the thirty-four contributors are a sufficient guarantee of the clinical value of the papers, of which some are summaries, while others contain critical comments. Without attempting to do more than illustrate the nature of this volume by referring to a few articles, it may be mentioned that special attention is paid to acute infections of the central nervous system, the lead treatment of cancer, abdominal surgery, and the physiology and surgery of the pituitary gland. The obstetrician will find a paper on obstetrics and gynaecology in the East particularly interesting, and an article entitled "Milk: its public health aspect" sums up lucidly and effectively a mass of information which will be as useful to general practitioners as to medical officers of health. The various papers on rheumatic manifestations are timely, and one on pulmonary tuberculosis, with a short summary of Calmette's method of vaccination, deserves to be read with care. Many practical therapeutical points are contained in accounts of the treatment of acute oedema of the lungs by atropine, of cardiac dropsy by novasurol, and of acute septicaemia by intravenous injections of mercurochrome. A well illustrated article sums up the present position of phototherapy.

Many of the diagrams and plates in the volume are of special merit. A valuable miscellaneous section includes an account of the progress of pharmacy and dietetics; descriptions of medical and surgical appliances; lists of new books various medical institutions, and spas; and an official and trade directory. The *Medical Annual* remains a most useful vade-mecum for the specialist as well as the general practitioner.

NOTES ON BOOKS.

THE numerous friends of the late Dr. ROBERT HUNTER STEEN will be glad that he lived to complete his little volume on *The Modern Mental Hospital*.[6] As Mr G. M. LEESON observes in an introduction, this work has a poignant interest, as it was carried out as a final act of service to the insane, in whose cause his life had been wholly spent. Dr. Steen was a distinguished psychiatrist, but in this book he makes no attempt to deal technically with his specialty. This is a simple and essentially human work in which the author aimed to provide the public with an account of life in a mental hospital. Two chapters are devoted to a "walk round" the mental hospital; then some details are given of the patients and their illnesses; and after an outline of the methods of treatment which are utilized, the book concludes with an account of the personnel, both administrative and nursing. His long experience as a medical superintendent enabled Dr. Steen to testify to the devotion to duty and the high qualities of the nursing staff. One of his objects in so doing was to attract to their ranks new recruits of the same type who may be reluctant to enter the nursing service of mental hospitals from a misunderstanding of the true nature of the ministration carried on within their walls. We hope that this interesting and enlightening book will have a wide circulation, as it cannot fail to do good.

MRS. SYDNEY STEPHENSON, whose name is such a part of modern literary activity in ophthalmic work, for her husband was the founder of the *Ophthalmoscope*, and until his death the editor of the *British Journal of Ophthalmology*, has herself penned a little *Guide to Ghent*,[7] and dedicated it to the memory of her husband. It is a most attractive and conveniently arranged volume, giving just so much of direction as will enable a visitor to find his way about. How full of romance the ancient city streets, what wealth of interest attached to the treasures hung in city hall and old cathedral! What a piece of work is the famous polyptych—"The Adoration of the Mystic Lamb," mainly the work of Hubert the elder van Eyck of 1420. At one time its beauties were unappreciated, for in 1816 six of the panels were sold to a Berlin museum. During the great war the principal panel was so cleverly hidden that the enemy's search for it was fruitless, and in 1918 the portions the Germans owned were restored to Belgium under the treaty, and parts that had gone to Brussels were regained, so that the whole is complete. The book may be commended to those who will visit Ghent at Whitsuntide for the congress of the Royal Institute of Public Health.

The eighth edition of *Wheeler's Handbook of Medicine*,[8] edited by Dr. W. R. JACK, has appeared after the short interval of two years since the last was issued. There is little change in the text, but the book as a whole has been carefully revised, and retains those features which have rendered it so popular in the past.

SATURDAY, APRIL 30TH, 1927.

THE SURGERY OF SPASTIC PARALYSIS.

THE abstract of a paper by Dr. Royle which we give elsewhere in this issue (p. 787) will, perhaps, serve to recall to the notice of surgeons a subject which appears to have received insufficient attention in this country. Dr. Royle has during the last few years given special attention to the surgical treatment of congenital spastic paralysis, and our readers will see from his paper that his results are striking. We need mention only one case in proof of this: a patient, who had for years been able to walk only with the aid of crutches, was enabled to play tennis within a year of operation. This was an exceptionally marked case, but in all the cases operated on, twenty-six in number, there was distinct improvement. The treatment, therefore, seems to merit consideration.

The operation advocated by Dr. Royle, which he has called sympathetic ramisection, is section of the sympathetic nerve supply to the affected limbs. The subject is of great interest both from the physiological and the surgical standpoint, and the idea underlying it is a development of recent years; an account of it was given in a series of lectures by Professor Elliot Smith based on Professor John Irvine Hunter's work, which was published in our first volume for the year 1925.

It appears from Dr. Royle's paper that he had come to regard the spasticity in congenital spastic paralysis as being due to a hampering of voluntary movement through overaction of the antagonizing muscles. He then, according to Professor Elliot Smith's account, called the late Professor John Irvine Hunter into collaboration, and a series of experiments on goats was carried out in order to obtain some precise idea of the conditions underlying spasticity, and to ascertain the effect of section of the sympathetic nerves supplying the limb muscles. Section of the sympathetic nerves suggested itself on several grounds. In the first place, there was Kulchitsky's observation that the medullated and non-medullated nerves supplying a muscle never terminated in the same muscle fibre, showing that so far as nerve supply was concerned there existed two distinct groups of muscle fibres in the voluntary muscles. In the next place, Boeke demonstrated that the non-medullated fibres belonged to the sympathetic system. Thus there were shown to exist a somatic and a sympathetic group of muscle fibres in the voluntary muscles. Further, Sherrington had shown that muscles possess a dual function, contractile and tonic or postural, the former leading to alteration in the position of a limb, the latter maintaining the limb in the new position; he also recognized that postural tone was of two kinds, active and passive, the former occurring in association with voluntary contraction, the latter being demonstrable altogether apart from voluntary contraction. Thus in the decerebrate animal, in which the influence of the higher centres is removed by transection of the midbrain, a condition of rigidity in extension is produced; in this condition periods of flaccidity occur, during which muscular contraction is absent. If, during this flaccid phase, the animal's limbs are moved, they maintain the position assumed, showing that the passive postural tone has been retained.

Such considerations as these led Hunter and Royle to conjecture that the sympathetic element in muscular innervation might be responsible, through overaction, for the spasticity or excess of tone exhibited in cases of congenital spastic paralysis and other forms of spasticity. Both their experiments on goats and the operations on human beings went far to confirm this view, and it was further corroborated by a series of beautiful experiments on the wing of the bird, in which Hunter analysed the parts played by the sympathetic and the somatic systems. The bird's wing was a particularly suitable subject for experiment, because alterations in tone were immediately visible in the drooping of the wing under the action of gravity, and the positions of the two wings could be compared. Hunter found that on dividing the cervical sympathetic the wing drooped somewhat, the tone of the affected wing being reduced, so that the normal posture could not be perfectly maintained. But considerable tone remained, tending to impose a partially folded posture of the wing. This residual tone Hunter attributed to the presence of an active postural tone induced through the somatic nerves, which in the absence of sympathetic innervation were unable to maintain the wing in the maximum position of flexion against the action of gravity. During light anaesthesia the effect was still more marked, this influence being partly removed. After voluntary activity, by flight, of the partially denervated muscle, the exhaustion of the somatic mechanism manifested itself in a striking degree, from which Hunter concluded that the sympathetic system plays a part during movement as well as at rest, the intermediate postures which the muscle assumes during movement being apparently supported by the sympathetic. By division of the posterior nerve roots, which transmit afferent impulses to the somatic element in the innervation, Hunter was able to demonstrate the retention of purely passive tone; in this state the wing exhibited no tendency to take up any particular posture, but when placed in any position maintained it indefinitely.

In discussing the question of operation, Hunter remarked that the posture of the patient is not the all-important criterion of rigidity. Even the flexed position may be due to a combination of both contractile and passive tone, the two together causing the rigidity. Conversely, the extensor position may be wholly due to contractile or active tone, in which case sympathetic section would be of no avail. The only patients who could be expected to benefit from the operation are those in whom voluntary control of their muscles is intact, but movements are hampered by excessive passive tone. There is a point connected with the treatment which is insisted on by Dr. Royle, and which, if disregarded, is likely to bring the operation into disrepute. The operation does not cure the patient, it merely removes the spasticity and leaves the way open for cure. The latter consists in the education of the patient in the proper use of his muscles and the employment of surgical measures, if necessary, to correct deformities and obstructions to voluntary movement due to contracture.

The work of Hunter and Royle covers but a single section of the wide field of sympathetic surgery. This branch of surgery may be considered to be in its infancy at present, and so far as this country is concerned its introduction has not hitherto been received with much enthusiasm. There can be little doubt

that much is still to be learnt, both on the anatomical and the physiological side, before surgeons will feel quite at home in dealing with the sympathetic; but that knowledge is rapidly advancing in both of these directions is abundantly shown in H. A. Harris's article on the sympathetic system in relation to vascular disease, which appears in another part of this issue. Given a sound knowledge of the anatomy and physiology, the possibilities of sympathetic surgery will become less obscure.

THE LEAGUE OF NATIONS AND TRAFFIC IN DANGEROUS DRUGS.

REFERENCE was made in the JOURNAL of March 12th last (p. 481) to a publication by the League of Nations reporting the appalling amount of illicit traffic in opium, morphine, heroin, cocaine, etc., which recent investigations had exposed. The publication of this document was cancelled and the copies sent to the publishers were recalled, but sufficient indication of its contents is contained in a report which the Advisory Committee on the traffic in opium and other dangerous drugs presented to the March session of the League's Council. The committee informed the Council that the progress made with the ratification of the Geneva Convention of 1925 "is most disappointing." That treaty cannot come into operation until it has been ratified by ten Powers, seven of which must have seats on the League's Council, and two of them holders of permanent seats. It was, however, reported that "only one State permanently represented on the Council and one State non-permanently represented have ratified the Convention"; promises of greater expedition were, however, made. Meanwhile the Hague International Opium Convention of 1912 is the only international instrument in operation to arrest or regulate this insidious and degrading contraband trade.

The committee frankly deplores the fact that its efforts and those of the League "had not been so successful as had originally been hoped in combating the illicit traffic." As the British delegate pointed out, "despite all the efforts of the committee, despite the increasing efforts made by many Governments, the position was still eminently unsatisfactory." The sources from which the supplies for the illicit traffic in these drugs are drawn are said to be unknown, although the factories in which they are manufactured are presumably under the control of the Governments concerned, and huge quantities of these dangerous drugs are being smuggled into China, India, and other countries through the post and otherwise. "The situation," as the British delegate observed, "seems a little short of absurd."

Some of the evidence of "the appalling extent and the very widespread ramification of the illicit traffic" in opium and other dangerous drugs, extracted by the committee from "the formidable document of sixty-one printed pages" whose publication is suspended, was cited in the article already referred to in the JOURNAL of March 12th. Tons of opium, thousands of ounces of morphine and heroin, and hundreds of ounces of cocaine have, in the course of a few months only, been seized in transit. International syndicates reap large profits by this nefarious commerce. The most ingenious devices are used to deceive and circumvent the customs authorities. Consignments, either labelled with the names of the manufacturers or unlabelled, dispatched from various European countries have been confiscated by the Chinese maritime customs.

In view of the state of affairs thus disclosed it was not surprising that the Italian representative, Signor Cavazzoni, who came as a new member of the committee, should have moved a resolution to the effect that, seeing that the manufacture of these drugs is vastly in excess of the world's needs for medical and scientific purposes, and that "in consequence the contraband traffic continues to increase," full application should be given to Article IX of the Hague Convention of 1912, with a view to ration the production of these dangerous drugs.[1] Signor Cavazzoni's resolution was nevertheless rejected by 7 votes to 2, only Siam voting with Italy for it. The representatives of Great Britain and India voted in the majority. The reasons vouchsafed for the rejection of the resolution were that it would reopen the question of the limitation of production of the drugs, which the Second Geneva Conference, after an acrimonious discussion which had led to the withdrawal of the United States and China, decided against; would arouse controversy over the functions of the Central Control Board; and would endanger "the compromise so painfully reached" in 1925. Nevertheless, Article IX of the Hague Convention has been endorsed by Article V of the Geneva Convention, and it is difficult to see why the Italian delegate's plea for direct limitation of the production of the drugs in question, under the authority of the League itself, should have been so emphatically rejected.

Readers of the JOURNAL will remember that we have from the first regarded it as almost impossible to grapple successfully with the control of the traffic in drugs of addiction except by limitation of their production—at their source—to the amounts required for medical and legitimate purposes. Surplus production, as experience has now conclusively demonstrated, is bound to result in diversion into illicit channels, in the misuse of drugs, medicinally beneficent and indispensable, for vicious and criminal purposes, and in the maintenance of a degrading and disreputable traffic for the benefit of unscrupulous profiteers.

POST-GRADUATE TEACHING IN BACTERIOLOGY.

THE appointment committees of universities, municipal bodies, or colonial authorities are, we are told, apt to find that the demand for fully trained bacteriologists exceeds the supply, particularly in the field of medical bacteriology; evidence of the truth of this is afforded by the advertisements which have appeared in our own columns within the last few years. This relative lack of well qualified candidates for appointments, which are in many instances not ill paid, as salaries for scientific posts go, is due, in part at least, to the absence of adequate training facilities. It is clear that only a bare minimum of bacteriology can be included in the already overcrowded medical curriculum; and the course of study for the Diploma in Public Health or in Tropical Medicine cannot cover more than a very small part of the ground, and that in an elementary fashion. Apart from the course for the Diploma in Bacteriology in the University of Manchester there is, at the present time, no systematic instruction in this subject available for post-graduate students in this country. The student who wishes to obtain an adequate training in bacteriology, after medical qualification, must do so on the apprenticeship system, by taking some junior post in

[1] This article runs as follows: "The Contracting Powers will enact pharmacy laws or regulations so as to limit the manufacture, sale, and use of morphine, cocaine, and their respective salts to medical and legitimate uses only, unless laws are already in existence. They will co-operate amongst themselves in order to prevent the use of these drugs for any other purpose."

a hospital or university laboratory. That this is an excellent way of attaining a practical knowledge of the subject is very true. It is, indeed, an essential stage through which the would-be bacteriologist must pass; but as the only available avenue of gaining knowledge it has serious disadvantages. The progress of this branch of science is so rapid, and the field covered so wide, that it is becoming more and more difficult for the student to gain an adequate foundation on which to build, without passing through a systematic course of study, organized to meet his particular needs. The recent foundation of the London School of Hygiene and Tropical Medicine has afforded an obvious opportunity to provide for this need in London; and, in view of the urgent demand for trained men, both at home and overseas, it has been decided by the board of management that the work of the Division of Bacteriology and Immunology shall begin in temporary premises in Gordon Square in October next, when Professor W. W. C. Topley, who, as will be remembered, was recently appointed to the chair of bacteriology and immunology in the new school, comes from Manchester to take up his duties. It is not intended, pending the completion of the school buildings, to provide instruction in those subjects for candidates preparing for the Diploma in Public Health; the lack of adequate accommodation would, indeed, render this impossible. The work of the Division will, during this interim period, be confined to the provision of a systematic whole-time course in bacteriology, occupying an academic year, for those post-graduate students who desire to take up bacteriological work as a career. There is, we understand, a possibility that the University of London will establish an academic Diploma in Bacteriology. Should this be so, the course of instruction will no doubt be planned to meet the University's requirements. Inquiries with regard to the course should be addressed to the Director of the London School of Hygiene and Tropical Medicine, at 37, Torrington Square, London, W.C.1.

CANCER IN SPAIN.

THE need for public enlightenment on the subject of cancer appears to be even more urgent in Spain than in this country, if one may judge by the volume recently published by Dr. Mariano Iñiguez y Ortiz, entitled *El Cáncer en España*.[1] The author is a believer in propaganda, and the book was written with the idea of informing the public on points that bear on the early recognition of the disease and other matters that are of public rather than of professional and technical concern. He anticipates that his book will be read by few, on account, not merely of the general indifference on the subject, but because vast numbers of Spaniards are unable to read at all, and as many more have no wish to; it should, however, prove a useful guide to those who work at propaganda by means of lectures, a method which the author considers inferior to written propaganda. The subject is dealt with on broad lines; it is introduced in an interesting way by tracing the changes that have occurred in the popular and professional views on cancer from the earliest times to the present day, and then reviews the statistics of the subject, the geographical distribution of the disease in the peninsula, the question of heredity, race, and civilization, and the means of combating the disease; finally, a chapter is devoted to the important assistance that can be given only by the public and the patients themselves. In Spain, as in other countries, there has been a progressive increase in the number of recorded cases of cancer in recent years, but the author attributes this to the earlier recognition of the disease, to more accurate diagnosis, and to the increased duration of life. The distribution of cancer in Spain is illustrated in several interesting maps. There is an area of high incidence in the central part of the peninsula, extending from the Pyrenees down to Madrid, contrasting strongly with the entire Mediterranean littoral, where, with the exception of Barcelona, the mortality is only about one-half of that in the central zone. With regard to the progress of knowledge in Spain, not only in relation to cancer, but to medicine generally, the author frequently refers to the indifference of the Spanish people. He quotes a saying of Ramón y Cajal that the great scientific discoveries have depended to a large extent on the element of chance, and that fortune has necessarily favoured those who, by scientific training, have learnt to appreciate the significance of phenomena. He draws the moral that it is only by establishing laboratories and similar institutions that Spaniards can hope to educate themselves and keep abreast of other nations in scientific discovery. Unfortunately the imagination of the Spaniard has, he says, become so impressed with the colossal figure of Don Quixote that idealism and pure science have become distasteful, and the stream of voluntary subscriptions for such institutions is wont to stagnate. Not the least interesting part of Dr. Iñiguez's book is the insight it affords into the national temperament. In speaking of the serious difficulties that are encountered in obtaining satisfactory death certificates and certificates of disease, he states that in many districts the diagnosis of cancer is regarded as equivalent to a sentence of death, and where this is so the natural benevolence of the Spanish doctor revolts against too harsh a decision; the patient may be a friend or relative, and sentiment and affection combine to temper the severity of the diagnosis. Again, it would frequently be considered a mere act of humanity to write down aneurysm of the heart in a case where the patient (unhappy girl!) had died of suppurative metritis and peritonitis. Laxity and indifference, however, appear to affect official quarters as well as the general public. Statistics of morbidity, the author states, cannot be said to exist in Spain, and as an instance of the regrettable inefficiency of the sanitary department, the responsible authority in this important matter, he mentions that as regards many diseases the mortality has been represented as being in excess of the morbidity.

GIAN BATTISTA PORTA.

THE series of portraits of Italian doctors and naturalists from the fifteenth to the eighteenth century published by the Italian historical institute of the healing art, to which we drew attention some time ago (December 25th, 1926, p. 1235), contains a woodcut of Giovanni Battista della Porta, otherwise known as Gian Battista Porta, taken from the first edition of his work *Di humana physiognomia*, with a short account of his life and work by Professor Capparoni. Porta was born at Naples in the middle of the sixteenth century, the exact year being uncertain, and died about 1615. He is best known for his work in optics, of which he was one of the pioneers, and the invention of the camera obscura is attributed to him. He had, however, many other claims to scientific distinction. With the aid of his brother he formed a collection of curiosities and specimens of natural history, which was one of the earliest examples of the modern public museum. Besides being a member of the Accademia dei Lincei, he founded the Accademia Secretorum Naturae, admission to which was confined to those who had made some discovery in natural science. He thereby incurred the suspicion of the ecclesiastical authorities, and was commanded by the Pope to close the academy. In the work entitled *Magia naturalis* he described the properties of the magnet, and appeared as one of the first students of toxicology by showing that the striking symptoms which used to be attributed to incantations were really due to the effects of poisons, such as

belladonna, stramonium, or nux vomica. Porta, however, did not escape from the influence of contemporary mysticism, as he fervently upheld the doctrine of signatures emanating from Paracelsus, according to whom a remedy indicated therapeutical properties by its external appearance. Not the least interesting of his works was that entitled *Di humana physiognomia*, by which he was the precursor of Lavater, Gall, and Spurzheim. He also wrote on plants and minerals, which he maintained were governed by the same laws as the animal kingdom.

METHODS AND PROBLEMS OF MEDICAL EDUCATION.

THE sixth series of *Methods and Problems of Medical Education*,[1] issued recently by the Division of Medical Education of the Rockefeller Foundation, New York, contains no fewer than twenty-eight articles, profusely illustrated by 218 plans and photographs, the account of the dermatological clinic of the Royal Hungarian University Pázmány Péter, Budapest, by Professor Ludwig A. Nékám, alone having thirty-six. As in previous numbers of this series, the accounts of the medical schools or their departments have been provided by those on the spot, and by the plans, budgets, and other details should prove a source of most welcome information to those about to organize new departments or laboratories. Most of the subjects dealt with in this instalment are of a scientific or laboratory nature rather than of a strictly clinical character. The first six articles are on the libraries of the medical schools of Peking, São Paulo (Brazil), Harvard, the Washington University (St. Louis), Kingston (Ontario), and McGill University. There is a photograph of the room set aside for the future Osler Library in the McGill Library, founded in 1823, which now contains 60,000 volumes; voluntary classes in bibliographical methods are held, during the course of which directions are given about collecting material for a paper and compiling a bibliography. The library of Washington University now possesses the manuscripts of the pioneer American physiologist, William Beaumont, and here again the librarian gives instruction to medical students. The anatomical departments of Trinity College, Dublin, Belfast, and Milan are described; Professor A. E. Boycott supplies an account of the pathological museum of University College Hospital, Professor Johannes Fibiger is responsible for full details about the institute of pathological anatomy in the University of Copenhagen, and his colleague Professor Oluf Thomsen for those of the institute of general pathology. The biochemical department of Tulane University, New Orleans, which has just started its independent existence, gives 200 hours' instruction in general biological chemistry to first-year medical students, whereas the handsome institute of physiology at Louvain, over which Professor A. K. Noyons presides, has the departments of physiological chemistry and of pharmacology attached to it. The institute of phototherapy at Florence, which was inaugurated in 1905, contains apparatus for high frequency as well as for *x*-ray diagnosis and deep therapy. The projected plans for the institute of physico-therapeutics so badly wanted at Jena are given, but the institute has never been built as the intending donor lost his fortune. Dr. Gibbon FitzGibbon writes on the Rotunda Hospital, Dublin, relating its eventful history and the present daily routine. Public health activities are represented by descriptions of the public health clinic at Dalhousie University, Halifax, and of the institute of hygiene at the University of Cluj, Rumania. The last two articles in the volume are of rather peculiar interest—namely, on the teaching of percussion, by Dr. F. X. Erben of the University of Vienna, and on visual instruction and the projection method of illustrating lectures and demonstrations, by Dr. Carl Jacobj, director of the pharmacological institute at Tübingen.

REST PAUSE INVESTIGATIONS SUMMARIZED.

WITH magnificent disdain for the economy which is said to be so urgent a necessity for this country, the Industrial Fatigue Research Board continues to pour forth literature. On March 26th (p. 582) we reviewed a report by Dr. H. M. Vernon and Mr. T. Bedford on rest pauses in heavy work. The Board has now issued a summary by Mr. S. Wyatt of the observations made by its various investigators on "Rest pauses in industry." It is to be hoped that the publications of the Board are read by the persons for whom they are intended. Mr. Wyatt concludes that suitable rest pauses lead generally to improvement in quality and quantity of output. Rest is particularly beneficial in repetitive work of a monotonous character: production is increased in processes which depend on the activities of the worker. It seems, however, that the published work on rest pauses raises more problems than it solves. The results are variable; but this is attributed in the report to unscientific methods of procedure. Careful investigation of the conditions of work should, it is said, be made before introducing rest pauses, since a rest may not be necessary in all cases. Sometimes short and more frequent rests are better than fewer but longer. Individuals have been found to react differently to rest; but Mr. Wyatt wisely recognizes that in practice it would not be possible to give each individual the dose of rest most suited to his or her temperament. Moreover, the woman operative is found to rest better in herds. "Her inclination to work is stimulated by the atmosphere of industry in the room." Mr. Wyatt suggests that the possibility of combining rests with team-work has not been sufficiently explored, so that, for example, with three workers to a machine each would rest for twenty minutes during each hour. In conclusion, the apology is offered for the report that it serves to indicate the number and variety of questions awaiting solution in this aspect of industrial work.

WHAT IS A SAVANT?

A FEW years ago Professor Charles Richet contributed a volume to a series of little books now being published in Paris describing typical characters of to-day—such as the politician, the priest, the diplomat, the lawyer, the peasant, and the workman. Professor Richet's volume dealt with the savant, and Sir Oliver Lodge has now translated it into English with the title *The Natural History of a Savant*.[1] Professor Richet begins by making the just observation that neither in English nor in German is there any word expressing the full meaning of the French term *savant*; certainly the German *Gelehrte* does not. The word "scientist," recently established in English on the recommendation of a number of experienced correspondents of *Nature*, comes nearer. Professor Richet, however, says that the true savant cannot combine any profession, save that of teaching, with his pursuit of knowledge. He is an explorer, confronted with innumerable mysteries which seem to bar the path of human intelligence, and goes on with his work without any thought of the practical outcome. He must possess originality, the critical faculty, technique, erudition, and the power to teach. It is natural, no doubt, that the physiologist and the physicist, for example, should take pride in the feeling that they belong to a race apart; that in the pursuit of pure science they are unconcerned with the practical importance of any discoveries they may make. But it is not possible to draw the

[1] *The Natural History of a Savant.* By Professor Charles Richet. Translated from the French by Sir Oliver Lodge. London and Toronto: J. M. Dent and Sons, Ltd. 1927. (Cr. 8vo, pp. xi + 155. 5s. net.)

distinction too absolutely, or to suggest, for instance, that Pasteur as a crystallographer was a savant, while his discoveries with commercial and medical applications made him something different. Was not the first biography of Pasteur entitled *Histoire d'un Savant par un Ignorant?* Professor Richet, though regarding physiologists as savants, seems to admit anatomists to the sacred circle a little grudgingly, apparently because he still looks on anatomy as an ungrateful science in which few discoveries are to be made. Indeed, Professor Richet himself ranks Ph. Sappey, professor of anatomy, among the finer types of savant. Professor Richet says that engineers and surgeons are not savants, because they have some other object than the discovery of truth. Yet a surgeon who designs successfully a new and daring operation has originality, technique, erudition—in his own subject—presumably the critical faculty, and is certainly engaged in the pursuit of truth. In only one point does such a surgeon fail to reach Professor Richet's standard of a savant—he need not be poor! But we are by no means certain that the emphasis laid on the poverty of the savant is justified. The pursuit of the savant may be comparatively unremunerative, but, like most professions, it would appear to produce a living wage. Perhaps Professor Richet is making a mistake in trying to establish the vocation of the savant as an independent pursuit. It seems more likely that there is something of the savant in all great men who use their brains in the search for truth, and that the mere decision to devote one's life to mathematics, physics, or physiology does not necessarily make a man a savant. Here we are met with the difficulty that we are dealing with a word for which there is no English equivalent. Perhaps the logical Frenchman has elevated into a type a condition of mind which is seldom seen in a pure form. At all events, Professor Richet's gallery of savants is curious in its comprehensiveness, for it includes Galileo, William Harvey, Francis Bacon, Ambroise Paré, William James, Sir William Crookes, Sir Oliver Lodge, Cesare Lombroso, and Frederick Myers.

HOOKWORM DISEASE IN CHINA.

AMONG the major scourges of mankind in the tropics and subtropics, none has achieved scientific interest in recent years to such an extent as hookworm. For this reason, and because of its omnipresence, it has received the attention of the International Health Board of the Rockefeller Foundation, and expeditions have been sent to investigate it in many different parts of the world. The most recent of these is one to China, under the guidance of Dr. W. W. Cort, assisted by Drs. Grant, Stoll, and other collaborators, a detailed report of whose studies has just been published.[1] It appears from this that many of the existing beliefs about the epidemiology of this disease in China are ill founded. It is not distributed generally—indeed, the whole of North and large tracts of Central and South China are so lightly affected that hookworm has no public health significance at all. In the few spots where hookworm disease (as distinct from hookworm infection) did occur, it was one of the major medical problems, and was found to be closely associated with the use of human excrement as fertilizer; but although night-soil is largely used throughout China for this purpose—they estimate that about 24 million tons are used annually—it was only in connexion with its use in mulberry cultivation that it became a serious source of disease. The second picking of the leaves, about the beginning of June, for the feeding of the heavy broods of silkworms, entails a big strain on the vitality of the tree, and about two to four weeks before this is done night-soil, collected for some time before, is heaped around the base of the tree and dug in—ideal conditions for the development of ankylostome larvae from the still viable eggs in the faeces (larvae which have hatched out before distribution are killed by the decomposition in the manure). When the peak of the infectiveness is reached, in two to three weeks, the pickers in their soft sandals come and stand in the mud close to the tree trunk to cut the leaves—ideal conditions for infection with the larvae. It is the combination of these two circumstances that leads to the enormous infection found in the Yangtze delta, in Kwangtun, and elsewhere. Hookworm disease in China, therefore, is not the general sanitary problem it is in other parts of the world; but it is a definitely economic one. If the farmer could afford or could be induced to discard the use of human manure it would be easily eradicated. As this was impossible (he is too poor for the first and too conservative for the second), studies were made on methods of reducing the amount of the infections in the night-soil. Storage for a month under summer conditions, or the addition of a small proportion of slaked or unslaked lime for a week to a fortnight, rendered the number of surviving larvae negligible. Thick sandals and other protections are urged, but Dr. Cort is doubtful if a largely illiterate and very conservative people, many of whom live in places inaccessible to ordinary transport, can be easily influenced by outsiders. He holds, therefore, that the first essential is an adequate modernly trained Chinese medical personnel. Once this has been achieved the people can be reached, and with education prophylaxis is easy.

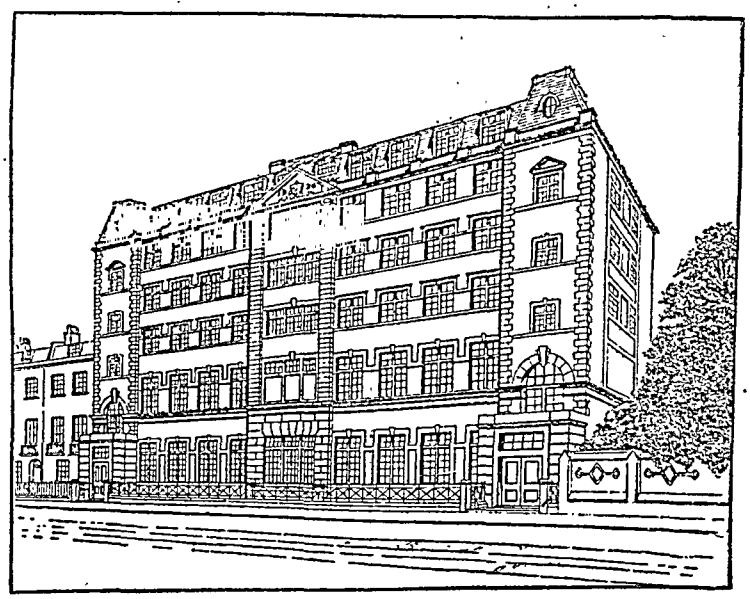
DAIRYING RESEARCH.

THE report for 1926 of the National Institute for Research in Dairying, established in connexion with the University of Reading, continues to show a depressing shortage of funds. Applications have been made to the Ministry of Agriculture for £23,000 for capital expenditure and for an increased annual grant, and to the Empire Marketing Board for assistance in carrying out researches on dairy products on behalf of the Dominions. The Institute was informed by the Ministry of Health that in the interests of national economy an annual grant of £800 could not be continued after last year; it had proposed to use the grant in developing a small branch laboratory at the School of Tropical Medicine in London for researches on the carriage of milk. The Institute desires to improve its farm buildings, to add a physiologist to its staff, to increase the number of its workers and the laboratory accommodation. In the meantime, pending the arrival of easier financial conditions, it is carrying out researches on the pasteurization of tuberculous milk, on black spot in Cheddar cheese, on oiliness in milk, and on black spots in butter; it has designed a method for concentrating bacilli in tuberculous milk whereby the delay involved in the animal inoculation test is avoided; it has invented a "preheater" for the whey-drying machine; and it is investigating milking machines.

THE KING has nominated Dr. Henry Hallett Dale, F.R.S., to be for five years a member of the General Council of Medical Education and Registration in the United Kingdom, in succession to Sir Nestor I. C. Tirard.



DR. EDWIN GOODALL, medical superintendent of the Cardiff Mental Hospital, will give the eighth Maudsley Lecture of the Royal Medico-Psychological Association on Thursday, May 19th, at 3.30 p.m. The lecture will be delivered in the Great Hall of the British Medical Association, Tavistock Square, and its subject will be "Some of the work done to elucidate the pathology of disease falling to be considered under the rubric 'insanity.'"

RESIDENTIAL CLUB FOR ST. THOMAS'S STUDENTS.

OPENING BY THE ARCHBISHOP OF CANTERBURY.

ST. THOMAS'S HOUSE, in Lambeth Palace Road, a residential club for students of St. Thomas's Hospital Medical School, was opened on April 26th. The house is a six-floored building, situated almost opposite the entrance to the medical school, and is designed to accommodate fifty students and ten hospital officers as residents, and to provide club facilities for all the students of the school.

The authorities of St. Thomas's have for some years past desired to provide residential accommodation for at all events a certain number of students. They have recognized that a large body of students living together in proper surroundings was likely to have a good effect on the well-being of the school. In addition to this, the post-war difficulty of obtaining suitable lodgings within easy reach of the hospital made the need more pressing. Lodgings like those let by Mrs. Raddle—"near Guy's, and handy for me, you know"—have possibly disappeared along with Mr. Bob Sawyer as a type of medical student; but the best of modern boarding establishments within the ordinary student's means is bound to suffer in comparison with what can be offered by a special hostel where the students enjoy a communal life.

ST. THOMAS'S HOUSE.

The students' club at St. Thomas's was formerly housed in a wing of the medical school, but when additional laboratory accommodation was required for the physiology department it was surrendered for that purpose, and the students took refuge in one of the old army huts which had been put up during the war. Meanwhile it was decided that, on a site on the opposite side of the road which had been acquired by the hospital some time before, premises specially adapted for a residential club should be built. The difficulty of financing the scheme led to a good deal of delay, but eventually the hospital authorities found themselves under the necessity of providing additional accommodation for their house officers, and therefore it was decided to combine this with the scheme for the students and to obtain authority to borrow the necessary money for the building operations. One of the hospital governors who was interested consented to lend half the sum required at a low rate of interest, and the remainder of the money having been obtained the work proceeded.

The building, which is now ready for occupation, has a very dignified appearance both within and without, and greatly improves the rather dingy aspect of the east side of Lambeth Palace Road. On the ground floor is an oak-panelled dining room, with office for the steward and the servery, and on the first floor the club room. Each of these rooms is nearly 80 ft. long by 35 ft. broad. In the club room a very handsome overmantel has been erected as a war memorial to St. Thomas's students, and was unveiled on the occasion of the opening of the house. A billiard room and a reading and writing room are provided, and by an arrangement of folding doors a musicians' gallery can be projected into the dining room and a stage into the club room. The four upper floors consist (apart from the quarters of the resident warden) of bedrooms for the students, certain house officers of the hospital, and the resident employees. The bedrooms are so arranged as to form comfortable sitting rooms during the daytime, and the chairs, tables, and bookcases have been designed with that end in view. Washing and bathroom accommodation is arranged in a central apartment on each floor. The building as a whole is fitted in an up-to-date style with a complete system of internal automatic telephones and electric clocks, and there is central heating with oil fuel, and a passenger lift. Generally, the furniture of the building is entirely finished in oak to match the permanent woodwork.

The opening ceremony was performed by the Archbishop of Canterbury, who at Lambeth Palace is a near neighbour.

The Archbishop was received by the Hon. Sir Arthur Stanley (treasurer of the hospital), Sir George Makins (chairman of the War Memorial Committee), and Dr. L. B. Maxwell (warden of St. Thomas's House), and in the dining room representatives of the medical staff and other officers of the hospital were presented. Afterwards, in the club room, Sir ARTHUR STANLEY extended a formal welcome on behalf of the hospital and medical school, mentioning the fact that when the present hospital was opened by Queen Victoria in 1871 the only club accommodation provided for the staff and students of the medical school was in a very gloomy basement under the lecture theatre. Not until twenty years later did the club enter into possession of the quarters recently vacated. After reciting the course of events already sketched, which led to the provision of the new building, Sir Arthur revealed the fact that the governor who had provided at a very low rate of interest half the sum necessary for the project was Lord Riddell, and that the sum so lent was £30,000. He thought that the governors and staff had once more illustrated the reputation of St. Thomas's for being up to date. In spite of its great age—it would be 700 years next year since the hospital was rebuilt and re-endowed by Peter de Rupibus—St. Thomas's was still in the forefront of medicine, surgery, and nursing. Its present buildings, although erected over fifty years ago, were still unsurpassed in design, and now in St. Thomas's House it had given a lead to other great hospitals to which medical schools were attached.

After Lord RIDDELL had briefly acknowledged the thanks expressed to him for having made the building possible, Sir CUTHBERT WALLACE, dean of the school, spoke briefly on the benefits conferred on the school by a residential club. One of the great advantages was that the first-year student was delivered from the lonely lodgings which had been very generally his lot. The close proximity of the club to the hospital had obvious advantages in professional training, and on the social side the club fostered that corporate life and fellowship which was no small factor in a school's efficiency, for, through men living together and inevitably talking "shop," education went on unconsciously in the hours free from classes and set tasks.

On behalf of the medical and surgical staff Mr. C. A. R. NITCH presented to the Archbishop a cheque for £700 for the furnishing of the club room. He mentioned that a few weeks ago it became clear that the club—or, rather, the amalgamated clubs of St. Thomas's—would have a heavy burden to face in the furnishing and equipment of the club room and the parts of the house other than the residential part (for which the hospital itself is responsible), and to ease the burden the staff had subscribed the amount.

The ARCHBISHOP OF CANTERBURY, in declaring the building open, said that there was no class of young men in the great metropolis whom he regarded with more hope and satisfaction than the medical students in the great hospitals, because, while their life lasted, if their intentions were fulfilled, they would be devoting themselves definitely and unremittingly to the setting forward of the common good and the combating of the common ill. Therefore he welcomed anything which contributed to making their student years more effective and, in consequence, their future professional career more fruitful. His Grace went on to speak of the long association of the Archbishops with St. Thomas's and with Lambeth generally, and the delight that it had been to himself and Mrs. Davidson to afford the hospitality of the beautiful palace garden (which adjoins the new club-house) to the staff and patients.

The LORD MAYOR OF LONDON (Sir Rowland Blades), who with Mr. Sheriff Shepherd was present to represent the commonalty and citizens of the City of London as governors of St. Thomas's Hospital, proposed a vote of thanks to the Archbishop for performing the opening ceremony. In seconding this, Sir GEORGE NEWMAN, chief medical officer of the Ministry of Health, said that the club was introducing into the life of St. Thomas's students a wholly new social opportunity. He recalled one student of old St. Thomas's, when it was situated in the Borough, who had gained an immortal name in English literature—John Keats—and the pathetic story of Keats's loneliness and isolation during his studentship. Social friendship and culture in the best sense were necessary to medicine, and these could only be ensured through university life. One of the endeavours of the twelve medical schools in London was to introduce a true university element and to make medical education in London of university standard. In the medical schools of London there was everything to make for great medical education, with the exception of the social culture enjoyed by Oxford and Cambridge men, which they missed when they came to London. Therefore, he hailed with the more satisfaction this development at St. Thomas's. St. Thomas's was likely to become more and more a medical school where social life as it existed in the old universities was a real and living thing. This was the way in which universities had been built. The social club in one form or another was a constituent element in true university education. He pointed to the old Italian universities. Men of many nations went to Padua and Bologna and other great Italian universities of the Renaissance, not only in order that they might learn things, but that they might participate in the life of the great residential communities which, as history showed, these universities more and more became. St. Thomas's House, said Sir George Newman, was the embodiment of what was begun many years before—an effort to make the social life among the students minister to the truest and highest education. Benjamin Jowett wanted his students to look upon their university institution as a great club, a great school, and a great church. No one who knew what medical education had done for this country and what it had still to do in the not remote future could doubt the proposition that all true medical education must secure in some degree those three elements.

Sir GEORGE MAKINS, chairman of the memorial committee, then requested the Archbishop to unveil the oak overmantel which had been put up as a memorial to those of St. Thomas's Hospital who fell in the great war. He said that on the central panel was inscribed a single sentence: "*Fratres suos huius domus filii pia memoria salutant*," which might be freely translated, "Brothers, the sons of this house salute your memory with reverence." He believed that that sentence would express the spirit of those who used the club room. The names of eighty-three men and one nursing sister would be inscribed upon panels to be erected in the central hall of the hospital itself.

Certain prayers were then offered, and the Archbishop drew aside the flag which had covered the memorial, after which John Arkwright's hymn, "O Valiant Hearts, who to your glory came," was sung.

The very large company present then viewed the building, and many expressions of admiration were heard for a club-house which in its appointments is well up to West End standards, and in its spaciousness exceeds them.

MINERS' NYSTAGMUS.

ADDRESS BY DRS. J. S. HALDANE AND T. L. LLEWELLYN.

DRS. J. S. HALDANE and T. LISTER LLEWELLYN, at a meeting of the Institution of Mining Engineers held at the Royal Technical College, Glasgow, on April 23rd, read an important paper on the causes of miners' nystagmus, in which they combat certain criticisms which have recently been restated against the conclusion now most widely accepted that the condition is due to defective lighting in the mines.

In their paper the authors state that owing to the amount of inconvenience, suffering, and anxiety which it causes among miners, and to the serious burden thrown on the industry by compensation, the prevention of the nervous affection known as miners' nystagmus has become a subject of considerable importance to mining engineers. In order to prevent miners' nystagmus the cause must be removed. The majority of those who have studied the subject closely have concluded that the essential cause is the defective illumination given by the safety-lamps used; and this was the conclusion of the committee appointed by the Medical Research Council to investigate the disease, the corollary being that every effort should be made to improve the lighting. The conclusion that defective lighting is the essential cause of miners' nystagmus has, however, been called in question, particularly by so well known an authority in ophthalmology as Dr. Freeland Fergus of Glasgow, and by Dr. Robson of Penarth.

Defective Illumination.

There is still much to be discovered as to the exact manner in which miners' nystagmus is produced, and as to conditions which favour its development. Yet there is no real reason for doubting that defective illumination is its essential cause, and that it can be almost entirely prevented by an attainable improvement in illumination. They restate the evidence that defective illumination is the essential cause, and then discuss the doubts which have been thrown on this conclusion.

The evidence is, shortly, as follows: As an occupational disease miners' nystagmus is peculiar to coal-miners, and most commonly found among coal-miners working with hand safety-lamps. The photometric measurements carried out showed that the light actually falling on the coal-face during work varied between 0.018 of a foot-candle in safety-lamp pits and 0.09 of a foot-candle in open-light pits (a foot-candle being the illumination produced by a light of 1 standard candle at a distance of 1 foot). As, however, the coal-surface is black, and reflects only about a tenth of the light falling on it, the illumination available for vision is only about a tenth of these figures. In no other kind of work is the available illumination even approximately so low as in the case of coal-miners working with the present ordinary hand safety-lamps, whether flame or electric lamps. This is not merely because the candle-power of the ordinary hand safety-lamp is low, but because, to avoid the great risks from breakage, it must be kept well away from the work, and because so little of its light is reflected from the black coal-surface.

The eye adapts itself in the most marvellous manner to differences in illumination, so that a man can see quite sufficiently well, for, at any rate, rough work, with an illumination which is only a minute fraction of that of daylight. There is, however, a limit to this power of sufficient adaptation, and it is evident that coal-miners, with the present usual types of hand safety-lamps, are working at about this limit.

The clinical evidence in support of this conclusion is very strong. Miners' nystagmus is uncommon in open-light pits and frequent in safety-light pits. It is almost unknown in the purely naked-light coalfields of Somerset and the Forest of Dean. In Scotland the incidence is lower than in England, where safety-lamps are more generally used.

Experimental work by Ohm (Germany) shows that light diminishes and darkness increases the oscillations of the eyes. Improvement of illumination has been followed by a reduction in the incidence of the disease. Miners' nystagmus hardly occurs at all, to judge from American experience, in pits where electric cap-lamps are used. This

is mainly owing to the fact that the light is much nearer to the illuminated surface, and nearness is a factor of enormous importance, since the light thrown on the illuminated surface diminishes in proportion to the square of the distance of the light.

Since miners' nystagmus as an occupational affection does not appear except with excessively defective illumination during work, it seems attributable to the constant strain associated with efforts to see with very dim illumination. In what, exactly, this strain consists is not yet known with certainty, although miners are conscious of extra strain or effort. Probably other sorts of eye-strain due to awkward positions during work increase the effect. It also appears to be the case that in different individuals the limit of defective illumination at which the dimness of the light begins to cause trouble varies, so that under the same conditions of lighting one man will get miners' nystagmus and another will escape. Individual limits in the sensitiveness of the retina and in what may be called the "*stability*" of the nervous system must come into play, and appear to be in their turn dependent on such conditions as hereditary tendencies, proper feeding, and avoidance of alcoholic excess. Nevertheless, the evidence indicates that miners' nystagmus is almost absent when the illumination is increased to such an extent as is usually attained in open-light or electric cap-lamp collieries.

Other Suggested Causes.

Since occupational nystagmus occurs only among coal-miners, it has naturally been suspected that something emanating from the coal is responsible for the affection, and Dr. Robson and Dr. Freeland Fergus have developed this hypothesis on separate lines. Dr. Robson suspects volatile or gaseous substances, while Dr. Freeland Fergus suspects infection. The authors consider that the objections to these hypotheses are overwhelming. In the case of volatile or gaseous substances, no measurable vapour is given off by coal of any sort at ordinary temperatures.

As regards the question of possible infection from coal causing miners' nystagmus, and the complaint being thus an infectious nervous affection, we think that the evidence is overwhelming that though miners' nystagmus is associated with the handling of coal, it is only when coal is mined under conditions of excessive darkness that nystagmus occurs, so that the darkness, and not any infection emanating from the coal, is responsible.

Conclusions.

In concluding their paper the authors make the following observations. We think that much misapprehension has arisen through confusion between the number of men who obtain compensation for miners' nystagmus and the number of cases of real disability due primarily to miners' nystagmus itself. Claims for compensation have spread as knowledge of the ease with which compensation may be obtained has spread; and, of course, this mode of spread simulates infection. Another factor has been the coincident spread of the idea that miners' nystagmus, however slight, is something which will, if it be allowed to continue, lead to complete disablement or even blindness. Still another factor is that when wages are low, or work slack, it may seem most profitable to go on compensation for miners' nystagmus. Hence the claims increase or diminish as wages diminish or increase. Thus, from the statistics of compensation cases we cannot at present judge with any certainty as to increases or diminutions in cases with real disability.

It is not economically possible to increase the reflecting power of the coal, so the solution of the lighting problem must be, either to bring the light nearer the working area or to increase the candle-power and area of illumination given by the safety-lamp. The electric safety cap-lamp solves the problem in the first manner: the light is brought nearer and the rays fall at right angles to the working area. The lamp moves with the workman, thus providing a uniform and steady field of illumination free from shadows. The illumination given by one of these lamps may be ten times as much as that given by a standard safety-lamp of the same candle-power placed 6 feet away. Unfortunately, the cap-lamp, although universally used in America, has not been taken up well in this country. We strongly advocate this type of lamp, and suggest that there is more chance of success here in Scotland, where the men are used to cap-lamps, than in England, where they would be quite new.

Ill health, fear of unemployment, poor wages, or quarrels with the management must all irresistibly point out to the man the wisdom of following the path of least resistance attained by certification. But over and above these cases some men fail more quickly or suffer more incapacity than others. Dr. Percival thinks there is an inherited predisposition, possibly the result of the inbreeding so common in pit villages. Ohm thinks there is an inherited deficiency in light sense which shows itself in a failure of dark adaptation. There is some justification for these contentions, but it must be remembered that as sons follow their fathers' occupations, members of the same family will be frequently affected, and the large proportion of latent cases in the pits makes it clear that susceptibility to the disease is probably universal.

However much can be done by suitable treatment of those affected, it is essential to emphasize again the desirability of preventing miners' nystagmus by increasing greatly the illumination of the surfaces at which the men are working. In many cases this increased illumination can apparently be obtained with the excellent electric cap-lamps now manufactured in England. Where these are unsuitable, better electric lamps or flame-lamps are needed, and the very important investigations referred to above indicate that with safety flame-lamps of ordinary weight it will shortly be possible to secure such an illumination as will reduce miners' nystagmus to quite insignificant proportions. It seems to us that mining engineers should aim at improving the lighting sufficiently to get rid of the miners' nystagmus bugbear and at the same time increase the working capacity of the miners.

THE COLLEGE OF SURGEONS OF AUSTRALASIA.

A MEETING of surgeons from New South Wales, Victoria, South Australia, Queensland, Western Australia, Tasmania, and New Zealand was held on August 25th, 1926, to consider the formation of an Australasian College of Surgeons. Delegates had been nominated at meetings of surgeons and specialists in the Australian States and New Zealand to act as provisional foundation members of the College. They were Professor F. P. Sandes and Dr. R. B. Wade (New South Wales), Sir George Syme and Dr. A. L. Kenny (Victoria), Dr. H. S. Newland and Dr. Bronte Smeaton (South Australia), Dr. W. N. Robertson and Dr. J. Lockhart Gibson (Queensland), Dr. H. S. Stacy, as proxy (Western Australia), Dr. D. H. E. Lines (Tasmania), Dr. W. E. Herbert (Wellington, New Zealand), and Dr. R. Gordon Craig, as proxy (New Zealand). Sir George Syme was appointed chairman, and it was resolved that the total number of founders of the College should be forty, distributed as follows: ten each for New South Wales and Victoria, five each for South Australia and Queensland, two each for Western Australia and Tasmania, and six for New Zealand. The following representatives were elected:—For New South Wales: A. J. Brady, William Chisholm, C. P. B. Clubbe, R. Gordon Craig, Thomas Fiaschi, Sir Alexander MacCormick, Frank Antill Pockley, F. P. Sandes, E. T. Thring, and Ralph Worrall. For Victoria: Sir James Barrett, F. D. Bird, H. B. Devine, A. L. Kenny, Felix Meyer, Reginald Morrison, D. Murray Morton, R. Hamilton Russell, Sir George Syme, and B. T. Zwar. For New Zealand: H. Ackland, L. E. Barnett, Sir Lindo Ferguson, Sir Donald McGavin, Carrick Robertson, and D. S. Wylie. For South Australia: A. M. Cudmore, Anstey Giles, A. M. Morgan, H. S. Newland, and T. G. Wilson. For Queensland: Donald Cameron, G. P. Dixon, J. Lockhart Gibson, E. S. Jackson, and W. N. Robertson. For Tasmania: D. H. E. Lines and John Ramsay. For Western Australia: F. A. Hadley and W. Trethowan.

The Constitution.

The following constitution was adopted:

1. That the name of the proposed association of surgeons should be "The College of Surgeons of Australasia."

2. That members of the College be designated as Fellows and be entitled to place after their names the letters F.C.S.A.

3. That the College of Surgeons of Australasia should be a voluntary association (that is, not incorporated under a Companies Act or under a Royal charter).

4. That the objects of the College should be: (*a*) To cultivate and maintain the highest principles of surgical practice and ethics. (*b*) To safeguard the welfare of the community by indicating that its Fellows have attained a high standard of surgical competency and are of high character. (*c*) To educate the public to recognize that the practice of surgery demands adequate and special training. (*d*) To promote the practice of surgery under proper conditions by securing the improvement of hospitals and hospital methods. (*e*) To arrange for adequate post-graduate surgical training at universities and hospitals. (*f*) To promote research in surgery. (*g*) To bring together the surgeons of Australia and New Zealand periodically for scientific discussion and practical demonstrations of surgical subjects. (*h*) To do all other things that may help to the better achievement of these objects.

5. That the qualifications for the Fellowship shall be such special training in surgery and such standard of conduct as shall be considered satisfactory by the governing body under the by-laws of the College.

An exordium prepared by Professor Sandes was adopted, subject to legal revision. It contained a paragraph committing the signatory to the acceptance of any penalties for infraction that might be imposed by the governing body under its by-laws—for example, expulsion or lesser penalties. A provisional executive to take the necessary steps to found the College was appointed as follows: Sir George Syme, provisional president; Mr. A. L. Kenny, provisional secretary and treasurer; and Messrs. Hamilton Russell and H. B. Devine. The annual subscription was fixed at five guineas.

The first meeting of the founders of the College was held in Dunedin, New Zealand, on February 5th, 1927, during the second Australasian Medical Congress of the British Medical Association, when Sir George Syme was elected president and director-general, and Sir Alexander MacCormick and Dr. L. E. Barnett vice-presidents. Dr. A. L. Kenny was appointed honorary secretary and treasurer. The tenure of office in each case was fixed at two years. Dr. R. Gordon Craig, Mr. H. B. Devine, Dr. H. S. Newland, Dr. W. N. Robertson, Mr. R. Hamilton Russell, Professor F. P. Sandes, and Dr. Ralph Worrall were elected members of the Council. By-laws were adopted providing for the election of a Council of ten by postal vote of the Fellows of the College, and the appointment of an executive committee of five. For the examination of applications for Fellowship of the College a Credentials Committee was established, to include three members each for New South Wales, Victoria, and New Zealand, and two members each for Queensland, South Australia, Western Australia, and Tasmania. It was decided that each candidate for Fellowship must be nominated by three Fellows of the College from the State in which he resides, who must apply to the secretary for an application form (to be signed by the candidate and his nominators) containing information concerning the candidate's medical training, hospital appointments, special researches, the percentage of his professional activity devoted to surgery or to one of the surgical specialties, and his contributions to medical literature. The candidate would also be required to name five persons as references, each of whom would be asked to supply definite statements about the candidate's surgical judgement and ability, with confidential information about his moral and ethical standing. Inquiry would also be made of Fellows of the College living in the vicinity of the candidate. The State Credentials Committee, acting as a preliminary court, would make its recommendation upon the evidence presented, together with such facts concerning the candidate as may be in the possession of the individual members of the committee because of personal acquaintance. In making such recommendation the Credentials Committee would take into consideration the candidate's (1) character and conduct, as evidence that he reflected in his practice high ideals of service and conduct; (2) specialization in surgery or in one of its departments; (3) extent of experience (not less than five years' surgical practice); (4) hospital appointments; (5) evidence as to competency in surgery; (6) surgical research. After five years from February 5th, 1927, a candidate must possess a senior surgical qualification, but at the discretion of the Council in the case of candidates of exceptional surgical ability or experience this requirement may be ignored. In order to foster the closest possible harmony with the British Medical Association the Credentials Committee is directed to inquire of the Association as to the eligibility of candidates.

It was decided that the Council shall be elected by postal ballot to hold office for two years; but that one-half of the members elected on February 2nd, 1927, shall retire at the end of one year, the Council determining by lot which of its members shall so retire. All members are eligible for re-election. Any Fellow of the College may be expelled, by a two-thirds majority of the general council, for a violation of the constitution and exordium. He will have the right to be heard at the meeting at which his expulsion is under consideration. At the annual meeting the Fellows of the College will receive the report of the Council and the statement of receipts and expenditure; any proposed amendment of the constitution of which notice has been given not less than six months before the annual meeting may be considered. Scientific discussions and practical demonstrations of surgical subjects will be arranged. At least one meeting of Fellows must be held in each State or the Dominion annually, and a distinguished surgeon from another State or the Dominion will be invited to deliver an address. The Council will appoint a committee for each State and the Dominion, selected from Fellows in such State or Dominion, to perform such duties as may be delegated to it by the Council. The Council will draw up regulations for the admission of honorary Fellows from outside the Commonwealth and the Dominion. The executive committee of the Council was authorized to obtain legal advice as to the proper method of formation of a body or bodies to carry out vigilance duties and to form such a body or bodies. The question of a base for the College at Canberra was left to the discretion of the president. It was resolved that all the surgeons and surgeon specialists who had consented to become provisional foundation members in the preliminary meetings for the formation of the College should be elected foundation Fellows.

A meeting of the Council of the College was held immediately after the conclusion of the first meeting of the founders, and the following were appointed to be the executive committee: President, Sir George Syme; honorary secretary and treasurer, Mr. A. L. Kenny; members, Professors F. P. Sandes, Dr. H. S. Newland, and Mr. H. B. Devine. Another meeting was held on February 7th, at which instructions were given to the executive committee to draw up a by-law for the election of junior members of the College, and to appoint trustees to hold property of all kinds in trust for the College. It was resolved to establish an Endowment Fund, and to invite Fellows to subscribe to it. It was also decided that the New South Wales list of provisional foundation members should be placed upon the same basis as regards election to Fellowship as that of New Zealand and Queensland—namely, that the founders of the College in the State of New South Wales should act and report to the executive committee.

The first meeting of the founders was continued on February 8th, when gifts towards the Endowment Fund were received from Dr. Gordon Craig and Sir Lindo Ferguson, and promises from Mr. H. B. Devine, Dr. W. N. Robertson, Sir George Syme, and Dr. G. S. Wylie. It was resolved that any entrance fee imposed should be ear-marked for the Endowment Fund. The question of the word "Australasia" in the title of the College was fully discussed, and all the founders were agreed that the title should remain as adopted by the delegates at the meeting in Sydney in August, 1926. It was generally accepted that Australasia included New Zealand. Mr. R. Hamilton Russell was appointed delegate of the College to the Lister centenary celebrations. The honorary secretary notified members that a parchment roll of membership would be prepared and forwarded to the Union Bank of Australia in each town where a Fellow resided, in order that he might be able to sign the roll. A form of certificate of Fellowship would be designed and sent to the Fellows. The founders also discussed the question of a surgical journal.

South Australia.

[FROM OUR OWN CORRESPONDENT.]

THE MEDICAL SCHOOL.

CONSIDERABLE changes have taken place recently. A great loss has been sustained by the sudden death early this year of the Angas professor of chemistry, Dr. E. H. Rennie. He, with Sir William Bragg, Professor Archibald Watson, and Dr. (*later* Sir) E. C. Stirling, formed in the year 1885 the advance guard of the original Faculty of Medicine. Contributions to anthropology and investigations of the fauna of Australia, and more especially of the marsupials, by Professor F. Wood Jones, F.R.S., have reflected immense prestige upon the University of Adelaide, but after spending seven years among us he has been attracted to Honolulu by the authorities of the Rockefeller Institute; there one special subject for investigation will be the actual effects so far, and the probable results in the future, of that intimate blending of so many races—Malayo-Polynesian, Iberian, Chinese, Japanese, and Teuton—which has been encouraged by the United States Government in the Hawaian Archipelago. Professor Brailsford Robertson has been "seconded" for one year at least, and lent to the Commonwealth Council of Science and Industrial Research in order to pursue his investigations on animal nutrition; fortunately his coadjutor, Dr. Hicks, the recently appointed professor of human physiology, is at hand to carry on the teaching. The vacant chair of anatomy has been widely advertised, and presumably the same course will be adopted with regard to the chair of chemistry. The jubilee of the University was celebrated last year: the progress made in fifty years in every direction is marvellous, though original research work is mainly confined to the Waite Institute of Agriculture; at the Adelaide Hospital, too, there have been rapid advances. Buildings recently erected now increase the accommodation for patients to 500 beds, exclusive of 220 devoted to infectious and incurable cases; in addition, the special obstetrico-gynaecological department will in all probability shortly be commenced. Meanwhile more suitable housing has been provided for the resident medical officers, who now number over twenty, as compared with two only some forty years ago.

THE BRANCH.

For a dozen years or so the Branch (South Australian) has been accommodated in the buildings originally acquired by members of the profession, under the title of the "British Medical Hall Co., Ltd." These buildings were to be transferred to the Branch so soon as satisfactory incorporation could be attained, but this process involved some legal difficulties. Now the premises have been sold, and the directors of the company have committed themselves to the purchase of a block of land on North Terrace, facing the University. Upon this block it is proposed to erect a building of several stories; it is to be made to pay for itself by the leasing of suites of rooms for members of the medical and dental professions. It is a bold enterprise for a small medical community such as ours to venture upon, but if not immediately remunerative it will constitute a valuable gift to the next generation. The Branch has been presided over recently by Dr. de Crespigny, who has just returned from a holiday in Europe, and by Dr. H. H. E. Russell. The Lister Orator for 1926 was Professor Wood Jones, who gave one of those characteristic addresses which have stamped him as a remarkable speaker and thinker.

IRREGULAR PRACTICE.

The troubles met with in the old country have taken root here also. The newly formed Association of Botanic Medical and Naturopathic Practitioners, whose diploma is spread out before me, bases its claim for recognition upon a still unrepealed Act of Henry VIII. A deputation waited upon the Chief Secretary, asking for legislation to enable them to be registered as a body entitled to practise their peculiar arts, to give certificates of health, and, what is still more necessary, certificates of the cause of death. Fortunately the matter was referred to the Medical Board for its opinion, and its report apparently satisfie Labour Government that it would not be wise to ob deputation's behest. The Crown law officers too received instructions to enforce the provisions o Medical Act as regards unqualified persons assumin title of doctor. Curious divergence of opinion as reading of the Act has been evinced by the judges o instance before whom the offenders have been brough doubts have been speedily cleared up on the appealing to the Supreme Court.

New Zealand.

[FROM OUR CORRESPONDENT.]

WELLINGTON HOSPITAL.

DR. D. M. WILSON has written a short history o Wellington Hospital, which is now being enlarged cost of £140,000. In 1841 the New Zealand Land Com had the responsibility of treating the sick in the colony, but it was apparent that soon the colonists t selves must assume this responsibility. Governor arrived in 1845, and set about the task of enforcing and order. The settlement at Wellington lived in fe Maori uprisings and there had been occasional skirm in the vicinity, and Governor Grey realized that if were to be peace between European and Maori each soon learn to understand the other. He proposed, t fore, to use a hospital as a colonizing agency, and dispatch to Lord Grey, Colonial Minister in Lon Governor Grey declared his intention of establishin hospital where Maori and European might be tre together and a bond of friendship formed between the races. The statesmen had more foresight than the ge public, for there was no public demand for a hosp Indeed, a prominent colonist, Mr. Brady, wrote to New Zealand Journal in London, stating that the clim of Wellington was so healthy that "the doctors are pelled to turn either farmers or publicans, as they nothing to do but to attend upon lying-in women."

A report of the work of the hospital sent by the Gover to the State Department in London on March 6th, 1 shows that already the hospital had done much "to g the attachment and promote the civilization of natives." The hospital was provided with a steam-b room and a sweating room, and a hot-water bath, to wh the patients were introduced upon first admission. the natives were admitted from their pas, where sanit arrangements were conspicuous by their absence, ablution facilities at the hospital were not with significance for them. The hospital had many vicissitu including damage by an earthquake in 1848, with int mittent tremors extending over a period of four d which partially destroyed the building. The first and so what primitive hospital in Wellington is, however, wor of remembrance as a noteworthy civilizing agency wh played a great part in cementing two races in harm and goodwill. The work done in the hospital was noteworthy. For instance, a Maori chief of high rank operated upon by Dr. Fitzgerald for the removal o large tumour between the shoulders, and this patient anaesthetized with sulphuric ether. When it is rem bered that this anaesthetic was not announced to world until November, 1846, in an American med journal, that Syme did not use it until 1847, and that N Zealand was at the ends of the earth, it says much Dr. Fitzgerald and his unnamed colleague that a Mr thus early received the benefit of the new discovery. 1849 Earl Grey presented to the Colonial Hospital Wellington a large engraving of Her Majesty Qu Victoria so that the natives might see the great wh chieftainess to whom they gave their splendid allegia and devotion, and not less to her successors.

PHYSIQUE OF SCHOOL CHILDREN.

A physical survey of 20,000 New Zealand school child has been completed, and compares favourably with a simi survey undertaken in 1913. The conclusions may be su marized thus: (1) New Zealand school children sh

superiority in height and weight when compared with the available statistics relating to those of Australia, Great Britain, America, and Toronto. (2) New Zealand town school children have definitely improved in height and in weight during the years 1913-25. (3) Sitting height relatively to standing height is less in New Zealand children than in Glasgow children. (4) There is no noteworthy difference to be found in height and in weight of New Zealand children grouped according to birthplace of parents. (5) Children of farmers are tallest and heaviest, and children of professional men are almost as tall as children of farmers, but show no excess in weight over the average. (6) The height and weight of children in rural schools are greater than in city schools, and the average physical development of children with good mental attainment is greater than of those with inferior ability.

About a thousand children at Christchurch have been tested for tuberculosis, and a beginning is being made at Wellington and Dunedin. Dr. Blackmore, general superintendent of tuberculosis institutions, states that there are several delicate and non-injurious tests which show infection, and recommends special treatment for the positive cases. There is good reason to suppose that a large majority of cases of adult tuberculosis have been infected in childhood, although Nature often stifles the infection in children. The open-air school movement is making headway.

Scotland.

ROYAL SIMPSON MEMORIAL HOSPITAL.

AT the annual meeting of the Edinburgh Royal Maternity and Simpson Memorial Hospital, held in the City Chambers on April 21st, reference was made to the proposal of the managers of the Royal Infirmary that when the grounds to the west of the Infirmary, at present occupied by George Watson's College for Boys, should become available in about five years, a complete obstetric and gynaecological department, with some 250 beds, should be erected there, and should be named the "Simpson Memorial." The proposal involved complete amalgamation, but under the most favourable conditions the hospital could not be ready for occupation for at least seven years from the present time, and meantime the Maternity Hospital must be maintained. A subscription income of at least £5,000 a year was required for ordinary maintenance. A source of revenue had recently been lost to the hospital because, in consequence of the extended period of training for midwives lately imposed by the Scottish Central Midwives Board, fewer pupil nurses now presented themselves for training. The directors of the hospital had therefore found it necessary to offer free training to such pupil nurses as had already had a general training in nursing. Nevertheless, in spite of the difficult financial circumstances of the hospital, any curtailment of its activity would be impossible in view of the great extent to which recourse was had to it by the public. The number of cases treated in the hospital during 1926 showed an increase of 172, and the number of women delivered in connexion with the hospital and its Leith branch represented 37.3 per cent. of the total births in Edinburgh, an increase of 1.8 per cent. over the previous year. Professor George Robertson, President of the Royal College of Physicians, in moving the election of the office-bearers, remarked that, in thinking of the centenary of the birth of Lister, it was natural to refer to the other great benefactor, Sir James Y. Simpson. The improvement of surgery had only been rendered possible by the happy combination of anaesthetics and asepsis, and everyone knew what an important part Sir James Y. Simpson played in the introduction of chloroform. The decision of the directors to give free training to all pupil nurses who had already had their general training was a simple act of justice. The great voluntary hospitals did not pay their probationer nurses adequately for the services they rendered. It was true that the nurses were being trained, but they were also working hard all day to keep the hospital running, and for these services the probationer nurse was entitled to payment on a more adequate scale than she got at present. The Simpson Memorial Hospital in this respect had taken a step in the right direction, and he appealed to the generosity and justice of the public to see that subscriptions were increased.

SMALL-POX IN DUNDEE.

At a meeting of the Dundee Public Health Committee on April 18th Dr. Burgess, medical officer of health for Dundee, said that there had been up to date 107 local cases of small-pox. These had all been of a mild nature and probably all would get better, though some would be slightly marked. It was unfortunate that during the past fortnight there had been a falling off in the number of people presenting themselves for vaccination. This was serious because, unless people were generally vaccinated, the outbreak might hang on for an indefinite time. At a meeting of the Forfar District Committee Dr. Sinclair, medical officer of health for Forfar county, obtained authority to offer free vaccination. The chairman of the committee, Colonel Fotheringham, remarked that even if the local authority had to pay 2s. 6d. for vaccination of each case, this would be a great deal cheaper than having an outbreak of small-pox in the district.

ROAD ACCIDENTS IN SCOTLAND.

From the Home Office return regarding the number of street accidents in 1926 it appears that out of the 138,774 people killed and injured in Great Britain during 1926, 12,684 were killed or injured in Scotland. Of these, 579 were killed and 12,105 injured. The details of these were: caused by omnibuses and motor coaches, 1,774 and 180; by tramcars, 1,147 and 15; by other vehicles, 6,940 and 325; horse-drawn vehicles accounted for 630 injured and 26 killed; pedal cycles accounted for 1,614 injured and 33 killed. Six police districts of Scotland—namely, Arbroath, Montrose, Nairn county, Hawick, Galashiels, and Lerwick—had no fatalities to report. The highest number of deaths (119) occurred in Glasgow; Lanark county followed with 75, and Edinburgh with 47; Dumbarton accounted for 31, Stirling county had 30, Fife county 22, and Renfrew county 21.

THE V.A.D. MOVEMENT.

Dame Oliver, controller of the V.A.D. Department of the British Red Cross Society, in an address to the annual meeting of the City of Glasgow Branch of the Red Cross Society on April 8th, said that to complete the strength of the Naval, Military, and Air Force hospitals 5,000 men and 20,000 women under the Red Cross were required. On the population basis Glasgow had been asked to provide 100 men and 200 women, but at the present time only 5 men and 33 women were available. The work consisted in the nursing of sick and wounded in hospitals, and the country desired that the branches, such as that of Glasgow, should enrol and train the personnel in the necessary technical experience. If Great Britain was again involved in war hostilities would commence by air attacks on a large scale and casualties in crowded cities would be very heavy. It was impossible suddenly to train the personnel for such an emergency. A secondary object of the Red Cross Society, through the Voluntary Aid Detachments, was to mitigate sickness among the civil population at all times. Colonel G. H. Edington said that in 1926 the financial position had slightly improved. With a view to stimulating interest in detachments the Glasgow Committee had inaugurated a scheme under which the city had been divided into areas, each of which would be in charge of a small committee.

DUNDEE HOSPITALS.

At the quarterly court of governors of Dundee Royal Infirmary it was intimated that the total number of patients who had been treated in the wards during 1926 was 8,093, as against 7,729 in 1925. The expenditure had been £50,884, and the amount in hand at the close of the year was £5,789. In the maternity department the number of patients had risen from 257 in 1913 to 676 in 1926; a new building to provide thirty-five beds was in course of construction. There was urgent need for a new dispensary.

The annual report of Dundee Infant Hospital states that the average daily number of children in hospital during the past year had been thirty-one. The Dundee Royal Infirmary has received a gift of £5,000 from Mrs. Ferrie of Cupar in memory of her sisters.

SCOTTISH UNIVERSITIES PARLIAMENTARY VACANCY.

An analysis of the voters outside the university towns who are entitled to take part in the Scottish universities by-election shows that these are scattered through every constituency in Britain, with the single exception of the eastern division of Norfolk. In the Marylebone district of Harley Street and Wimpole Street there are over 200 voters who presumably are, in the main, doctors of medicine. An interesting point regarding the right to vote arises in connexion with a by-election. Graduates may have three qualifications for a parliamentary vote: (1) a residential qualification; (2) a business premises qualification; and (3) a university qualification, and at a general election they may vote only in respect of two of these. Electors who at the general election chose to exercise the qualifications in regard to residence and business premises were debarred from voting in the universities constituency. Such persons, however, are not debarred from voting for the university member now in the by-election.

England and Wales.

LORD LISTER AND NORWICH.

DR. MICHAEL BEVERLEY has contributed to the *Eastern Daily Press* a note about the reception of the Listerian system in Norwich in the seventies. Dr. Beverley went to Edinburgh in 1871 with an introduction to Mr. Lister from his friend Mr. William Cadge. Dr. Beverley was cordially received, and spent a month in watching Mr. Lister's hospital and private operations, and familiarizing himself with the antiseptic system, in which the carbolic spray was then used. On his return to Norwich he carried this out for Mr. Cadge, who at once adopted it, although at the time he had few followers, his hospital colleagues declining to use it. The house-surgeon, however, became an enthusiast, and used the spray and antiseptic dressings in Mr. Cadge's cases. In this way, Dr. Beverley says, the Norfolk and Norwich Hospital was probably "the first provincial hospital to adopt the antiseptic system, and that great surgeon, William Cadge, was one of its first, if not the first of its pioneers." In a communication to us Dr. Beverley recalls that he was present at Lister's introductory address at King's College, "a never-to-be-forgotten function—at once so disappointing to the packed audience of London surgeons, but so characteristic of Lister's thoroughness in all he undertook." The address was on the nature of fermentation, an understanding of which was, Lister pointed out, the foundation stone of the antiseptic system. He illustrated the general principles by describing and demonstrating the lactic acid fermentation of milk. The disappointment of the packed audience to which Dr. Beverley refers was due to the apparent remoteness of the topic, but the lecture, as Dr. Beverley says, was characteristic of Lister's thoroughness in all he undertook. Dr. Beverley illustrated his recent note in the newspaper by a facsimile of a letter, dated October 13th, 1904, in which Lister, while expressing his regret at his inability, owing to the state of his health, to be present at the dedication of the Cadge memorial window in Norwich Cathedral, which he had been asked to unveil, said that he would be glad to take part "in honouring the memory of one whom I respected so greatly as William Cadge," and sent a subscription.

EXTENSION OF KING EDWARD VII HOSPITAL, WINDSOR.

An extension of the King Edward VII Hospital at Windsor was opened by Their Majesties on April 20th, and was named the King George V Wing. This hospital, formerly known as St. Peter's, which serves not only Windsor and Eton but a large surrounding district, was originally founded as a dispensary in 1818; it became an infirmary in 1857, and after many extensions was moved to its present building in 1909. Since then various additions have been made, including an x-ray department, a pathological laboratory, special wards for women and children, an orthopaedic annexe, and nurses' quarters. The new wing brings up the total bed accommodation to 125, and the hospital now has fifty beds for men, forty for women, twenty for children, and fifteen private wards for patients of small means. These private wards are stated to be in great demand. The cost of the new wing, including equipment, furniture, and linen, has amounted to £11,780, the whole of which has been subscribed. A new hostel annexe for nurses, however, has still to be provided. An address to Their Majesties was read by Viscount Burnham, chairman of the governing body; and the King, in reply, after a reference to the association of his family with hospital work in Windsor, said: "The remarkable progress in the activities of your hospital during the short space of twenty years bears striking testimony to the zeal and energy of the authorities, as well as to the public spirit and generosity of its benefactors. But there is no finality in hospital work, and you remind us that, at the very moment when the new extension is completed, you are faced with the need for yet another addition, a new hostel for nurses, to build which I hope and trust the necessary funds will soon be available." The King and Queen were then taken round the hospital by Viscount Burnham, Dr. W. H. W. Attlee, senior physician, Sir Joseph Skevington, senior surgeon, the matron, and others. After having spoken to several of the patients, the King expressed a wish to see the medical staff who gave their services to the hospital, and they were accordingly presented. It was announced that one bed in the new wing had already been endowed with £1,000 by Mr. and Mrs. Noel Trotter of Ascot, in memory of Lord Lister and in celebration of the royal visit.

THE BOLINGBROKE HOSPITAL, WANDSWORTH COMMON.

The new wing of the Bolingbroke Hospital, which has been erected at a cost of nearly £100,000 in memory of the late Mr. William Shepherd, was opened on April 4th. By this extension a new block of wards is provided, the out-patients' department has been reconstructed, and new residential accommodation is made available for nurses. The Lord Mayor and Lady Mayoress attended the ceremony and opened the new operating theatres. Sir Henry Jackson, M.P., treasurer of the hospital, said that the new wing had been opened entirely free from debt in spite of the financial stringency of the past two years. An additional annual income of £9,000 would be necessary for its upkeep, but it was hoped that this money would be contributed by public generosity. The final balance of the building fund was obtained at a festival dinner at the Mansion House on April 1st, when the Lord Mayor gave a brief history of the hospital since its foundation in 1881, and appealed for £15,000; towards the end of the evening it was announced that over £18,000 had been received. It was stated that during 1926 there had been 1,130 in-patients at the Bolingbroke Hospital, and 36,000 out-patient attendances; 1,200 major and 1,387 minor operations had been performed.

CENTRAL MIDWIVES BOARD.

At the meeting of the Central Midwives Board for England and Wales, on April 7th, Sir Francis Champneys was re-elected chairman; other re-elections and elections to the Board were: Miss Edith Greaves, Miss Ada Davies, Dr. F. N. Kay Menzies, and Mr. A. B. Maclachlan by the Ministry of Health; Mr. Victor Bonney, M.S., F.R.C.S., by the Royal College of Surgeons; Mr. Robert Arthur Lyster, M.D., D.P.H., by the Society of Medical Officers of Health; Mr. Charles Sangster, M.R.C.S., L.S.A., by the Society of Apothecaries of London. The revised lists of examiners, lecturers, institutions where lectures are delivered, and institutions, homes, and midwives at which and under whom midwives may be trained, were approved for the year ending March 31st, 1928. Dr. Lyster moved, and the Board approved, the following resolution:

> That, it appearing that by the combined operation of Section 14 (1) of the Midwives Act, 1918, and Rule E. 20 of the Board's rules, a local supervising authority may be called upon to pay the fees of a registered medical practitioner called in by a midwife in a case of emergency, without regard to

the time when medical assistance is rendered, and it also appearing that a regulation of the Ministry of Health makes it illegal for a local supervising authority to pay the fee of a registered medical practitioner for assistance rendered after the lapse of a period of four weeks from the date of the confinement, it is desirable that the Board approach the Ministry of Health with a view to seeing if the regulation of the Ministry of Health can be amended so as to bring it into harmony with the Board's rules.

Ireland.

DEPUTATION TO THE MINISTER OF LOCAL GOVERNMENT AND PUBLIC HEALTH.

A DEPUTATION from the Irish Medical Committee, consisting of Drs. R. J. Rowlette, A. McBride, J. B. McClancy, J. P. Shanley, M. O'Brien, T. Hennessy, and Mr. C. H. Gick, waited on the Department of Local Government and Public Health in connexion with the following matters: (1) The transfer of medical officers under Section 5 of the Local Authorities (Officers and Employees) Act, 1926; (2) private patients in county and district hospitals; and (3) the remuneration of registrars of births, deaths, and marriages. The deputation was received on behalf of the Minister for Local Government and Public Health (who, owing to another engagement, was unable to be present) by Mr. McCarron, secretary, and Dr. E. F. Stephenson, chief medical adviser, of the Department of Local Government and Public Health. With regard to the transfer of medical officers under Section 5 of the Local Authorities (Officers and Employees) Act, 1926, the deputation urged that the Minister should refuse to sanction any transfer made as promotion unless the officer transferred was entitled to promotion on the grounds of merit and long service, in accordance with the intention of Section 5 of the Act. Mr. McCarron and Dr. Stephenson agreed that the section quoted had for its object the promotion of existing officers on the lines stated by the deputation, and undertook to convey the views of the deputation to the Minister. With regard to the admission of private patients to county hospitals, the deputation, whilst satisfied with the draft regulations forwarded by the department to the county health boards for adoption, pointed out that these bodies did not show any desire to put them in force and thus enable the doctors attached to the hospitals to arrange with private patients for payment for their medical attendance as provided for in the draft regulations of the Department of Local Government and Public Health. The deputation was informed that the department would use its influence in the first instance to have the draft regulations adopted by the health boards, and in the event of their refusal it would consider further representations from the profession. In connexion with the increased remuneration for registrars of births, deaths, and marriages, the deputation was invited to prepare a memorandum stating the position of these officials. Mr. McCarron and Dr. Stephenson considered the fees paid at present for this work were inadequate. More than 90 per cent. of the registrars in Ireland are dispensary doctors and the registration areas correspond to their dispensary districts.

INCREASED AMOUNT OF SICKNESS BENEFITS.

Lady Aberdeen, president of the Slainte Approved Society, in moving the adoption of its annual report, referred to the very high rate of sickness benefit paid to insured persons as the result of their being certified as incapable of work owing to some rheumatic complaint. The report for the year ended December 31st last stated that during that period claims were paid to 6,508 members, as against 6,060 in 1925, the total paid in benefits being £32,518 3s. 2d., as compared with £30,352 18s. 4d. The committee of management was much concerned regarding the inadequacy of funds for the payment of sanatorium benefit to insured persons, and the question was receiving the consideration of the Approved Societies Association. During the year further progress had been made and the membership maintained, [illegible] large number of members ceasing insur[illegible] causes. The financial statement showe[illegible] £36 5s. 7d.

Correspondence.

THE USE OF TUBERCULIN.

SIR,—In your issue of April 2nd (p. 641) Sir Robert Philip says that many persons seem to regard the subject of tuberculin as a *terra incognita*, but that he has used it much and consistently since its introduction in 1890, and is puzzled to understand the difficulties frequently expressed. Sir Robert Philip, however, does not give us definite information upon the exact methods he has adopted for diagnosis and treatment. There are many different ways of administering tuberculin, and many points upon which there is extreme diversity of opinion. In diagnosis there is the cutaneous, intracutaneous, and subcutaneous method. In treatment there is the method of obtaining allergy and the quite opposite method of creating great and lasting immunity by large doses. There is also the method by inunction. Would that Sir Robert Philip would give, not only his Edinburgh students, but the whole world concrete facts and deductions from his own ripe experience. What are his views upon the idea of danger arising from the subcutaneous injection of tuberculin for the early diagnosis of tuberculosis in accordance with Koch's exact instructions? This is a question he can easily answer if he has used the method. I say, after an experience over a period of thirty-five years in many hundreds of cases, that there is no danger.

Sir Robert Philip expresses himself as being puzzled to understand "the difficulties frequently expressed" with regard to the use of tuberculin both for treatment and diagnosis. From a large experience I say positively that there are difficulties, and great difficulties, in the administration of tuberculin if the method of large doses approved by Koch himself and his best known pupils is used in every chronic form of simple tuberculosis.

Sir Robert Philip tells us that the properties and value of tuberculin are demonstrated to all students graduating at the University of Edinburgh, and that tuberculin is in daily use in the several medical institutions which are linked up with the University department. Is it given to ambulatory cases? If so, by what method and with what results?

In the BRITISH MEDICAL JOURNAL of April 21st, 1923, I used these words: "I do not approve of his [Petruschky's] method of dosage, and I do not trust his method of inunction." I believe that Sir Robert Philip advocates Petruschky's inunctions, as he formerly advocated Béraneck's tuberculin. In the article quoted I also said: "I can only be convinced by the details of protocols in evidence that Sir R. Philip can in any way approach the success I have achieved by large doses given subcutaneously."

I have placed my cards on the table in the public interest, and it would be a great public service if Sir Robert Philip would do the same. We now want evidence, not opinions or impressions. Would it not be well that the evidence both of Sir Robert Philip and myself should be submitted to an unbiased tribunal of research workers and statisticians, in order that the true value of tuberculin in the diagnosis and treatment of tuberculosis may be ascertained?—I am, etc.,

London, N.W.1, April 18th. W. CAMAC WILKINSON.

STATISTICS OF TUBERCULOSIS.

SIR,—According to statistics tuberculosis is dying out; but statistics can prove anything. A patient who had been some time in the sanatorium was sent home on April 16th and died on April 18th, a couple of days after being discharged. I suppose according to the statistics he would be put down as "improved," not as a death.

I think I can safely say 50 per cent. of so-called cases of tuberculosis in the sanatoriums are not tuberculosis. I believe other practitioners will agree as to the value of statistics and sanatoriums.—I am, etc.,

Woodlands, Doncaster, April 20th. T. L. ASHFORTH.

VENESECTION.

SIR,—Amongst the many questions raised by the discussion on venesection reported in the BRITISH MEDICAL JOURNAL of April 16th (p. 721) is that of the explanation of the fact that venesection, after having remained so long in vogue, should have fallen into almost complete disrepute. Not to bleed a patient with "sthenic" pneumonia would at one time almost have laid the doctor open to a charge of malpraxis, if the patient died. About thirty or forty years ago, on the other hand, a doctor's reputation might have suffered if he bled the patient and the patient died. Indeed, hospital patients did usually die when they were bled, or given champagne, for both were reserved for really desperate cases. Forty years earlier how hard it was to discontinue the custom of bleeding in country districts in certain diseases is well illustrated by the following circumstances, which I heard from my father (*Reminiscences of Sir H. Weber*, 1919, p. 48):

> About 1850, when Sir J. Y. Simpson paid a visit to the Klinik at Bonn, my father was appointed by his uncle, Professor Friedrich Nasse, to show him everything he cared to see. Simpson explained that the venesection treatment of pneumonia had been completely abandoned at Edinburgh, and asked my father what would happen if he were to treat pneumonia patients at the village of Kessenich (the poor of which were under the care of the Bonn Klinik) without bleeding. My father answered that if the patient died without being bled the student or assistant from the Klinik who had attended the case would probably be waylaid and unmercifully beaten. This actually happened at Kessenich soon afterwards, when, with Professor Nasse's consent, bleeding was discontinued.

Now, bleeding for various conditions has become relatively common again. Recently I had a patient with the extremely rare maldevelopment known as coarctation of the aorta (stenosis of the aortic isthmus). I looked up the first two records of cases in which any clinical details were given (Morgagni, 1761, and R. Graham, 1814), and found that the three cases, according to the *clinical* notes, resembled each other in nothing excepting that all three were bled and all three died (my case had sudden apoplexy from rupture of a cerebral aneurysm).

Very important were Dr. H. French's remarks regarding periodical abundant blood-letting for erythraemia (splenomegalic polycythaemia). I would, however, like to know whether there are any contraindications for bleeding in this chronic disease, which perhaps may be regarded as a generalized overgrowth in the haemopoietic system, analogous to the overgrowth in the cutaneous system in ichthyotic patients. Certainly, in elderly debilitated subjects of the disease I would be very cautious in regard to suggesting treatment by benzol, phenylhydrazine, or even by the application of x rays to the long bones.—I am, etc.,

London, W.1, April 22nd. F. PARKES WEBER.

SIR,—Dr. Herbert French's remark, quoted in your issue of April 16th (p. 722), that physiologists teach that venesection is useless, is by no means a correct statement of physiological opinion. Professor McDowall has already pointed out one way in which venesection can be shown experimentally to be of value, but neither he nor any speaker in the discussion mentioned another factor which plays an equally important part.

If, in man, about 500 c.cm. of blood is withdrawn within a short space of time, the blood volume is temporarily lessened by about 10 per cent. The initial volume is rapidly made up by the passage of fluid into the circulating blood, whereas the red cells are not replaced for at least some days. The result is a lowered red cell content; in consequence there is a decrease in the viscosity of the blood, for this depends principally on the red cell content. The fall in viscosity is about 10 to 15 per cent. in these circumstances, for the viscosity falls somewhat more rapidly than the cell content in suspensions of concentration comparable with normal blood.

The work done by the heart varies directly with the viscosity, and also with the arterial pressure maintained; if, after the bleeding, the pressure is rapidly restored owing to peripheral vaso-constriction, it follows that the work required to be done by the heart will be diminished in proportion to this new viscosity, or by 10 to 15 per cent. This diminution in the work of the heart, maintained over a period of several days until the red cell content approaches the normal, is by no means negligible.

The work done by the right side of the heart will, of course, depend on this new and lessened viscosity and on the pulmonary pressure.—I am, etc.,

Department of Physiology, Edinburgh University, April 24th. ERIC PONDER.

THE PUBLIC, THE DOCTOR, AND THE MASSEUSE.

SIR,—The attention of the Council of the Chartered Society of Massage and Medical Gymnastics has been called by several of its members to the recent correspondence in your columns under the heading of "The Public, the Doctor, and the Masseuse."[1] In the absence of specified instances it is, of course, impossible to say how closely the allegation that diathermy and phototherapy is "constantly" being carried out by masseuses with much danger to the patients corresponds with fact, but it may not be out of place to remind your readers that the members of the Chartered Society, before receiving their certificates, pledge themselves "not to undertake *any* case except under the direction of a registered medical practitioner."—I am, etc.,

E. C. PERRY,
Chairman of the Council, the Chartered Society of Massage and Medical Gymnastics.

London, W.1, April 25th.

LISTERISM IN LONDON.

SIR,—In some of the addresses given during the Lister celebration a much too unfavourable view was taken of the position of surgery in London at the time of his advent. To accept the more severe strictures would be, not only to ignore the work of many of those who had adopted the methods, but would be a reflection on the influence of Lister himself.

Amongst those who sought the great master in 1868 were two young London surgeons, Marcus Beck and Henry Howse. The former became attached to University College and the latter to Guy's. When Howse became assistant surgeon in 1870 the wound was irrigated by a drip of carbolic lotion from a container suspended above the table. Later the hand spray replaced the drip, and was worked by relays of assistants. Howse, as all who knew him will recall, was exacting in attention to the most minute details, supervising or himself making the dressings in all important cases. Imbued with a true spirit of research, and being a sound pathologist as well as a practical surgeon, he rapidly though cautiously enlarged the field of operative surgery. When I became one of his dressers in 1874 we dressed as many as four cases of excision of the knee in an afternoon. This was an operation rarely performed at that time on account of the mortality rate. Howse, by attention to the details of Lister's methods and by his fine technique, brought the operation to such perfection that failure was unknown. He had raised the operation of gastrostomy from something like a 90 per cent. mortality to one of comparative safety. And so with ovariotomy, amputations, trephining, etc. So confident had Howse become in the security of the antiseptic methods that I have seen him take a child from the erysipelas ward, amputate the thigh, and return him to the same bed. These personal experiences occurred three years before Lister came to London, and the field had increased enormously by the time of his arrival. No better tribute could have been paid to the value of the new methods, and no one rejoiced more than Lister himself. On Lister's coming to London the two men soon became on friendly terms, for in the pupil the master recognized one who had demonstrated the truth of his principles and had become one of the pioneers into the unexplored regions of surgery.

Howse's junior colleagues followed his lead, so that by 1877 all but the three seniors had adopted Lister's methods.

Of the work at University College the one who could tell us most has, alas! gone to his rest; however, Godlee writes thus in the biography: "But the only two London surgeons in early days who carried out the treatment thoroughly

[1] See BRITISH MEDICAL JOURNAL, December 11th and 18th, 1926, pp. 1143 and 1195, and January 8th and 22nd, 1927, pp. 81 and 164.

and efficiently in hospital practice were Howse of Guy's and Marcus Beck of University College." At St. Thomas's McCormac and Croft were exponents of the method, and the former had successfully employed them in the Franco-Prussian war of 1870. The oncoming surgeons at this hospital were, I had reason for knowing, firm believers.

In tracing the growth of Listerism in Germany, it will be noticed that Godlee begins with Volkmann in 1872, so London can claim a two years' start, and that with the complete method learnt under Lister himself.

It is a remarkable fact that while in Germany Listerism found ready acceptance, it was not until 1878 that carbolic was used in Paris; yet it was here that Pasteur laid the foundation on which Lister built.—I am, etc.,

London, W.1, April 16th. CHARTERS J. SYMONDS.

TRAUMA AS A CAUSE OF AURICULAR FIBRILLATION.

SIR,—There are several points in the letters of Dr. Brockbank and Dr. Stephens (April 9th, p. 699) which merit a reply.

It is gratifying that the former is prepared to modify his original view and is "inclined to believe that strain affecting an already diseased ventricle or a heart with some abnormality might induce auricular fibrillation secondarily," but, of course, as he says, "proof is difficult." There will always be many instances in which it is far from easy—or may even be impossible—to prove any causal relationship between the physical strain and the fibrillation, but our object was to demonstrate that this causal relationship does sometimes exist and that there are cases in which the relationship between the strain and the fibrillation can be reasonably inferred.

Dr. Brockbank stipulates that some proof is required that fibrillation was not present before the physical trauma. Such evidence must be objective, or subjective, or both. In Case IV both were present. This patient is a medical man who is well aware when fibrillation is present: he knows when it begins and when it ceases. In 1922 this man, by a happy chance, was examined for life insurance, and his heart was passed as normal in every respect. The next day he ran hard for a train and was at once conscious of the specific change in cardiac rhythm, and when I examined him fibrillation was present. In 1926 there was a similar sequence to the same form of effort. Here we have an example of cause and effect, and convincing evidence that the heart rhythm was normal immediately antecedent to the sudden physical strain.

Since the publication of our paper (J. H. and H. W. J.) medical man has written to me giving his own personal experience. His first attack of fibrillation followed a day strenuous cycling, a form of exercise in which he had not indulged for three years. His second, third, and fourth attacks of fibrillation followed unwontedly severe exercise—such as vigorous sawing and swinging the car. Here again we have a medical man who knows when his heart is fibrillating and who is quite conscious that the fibrillation was not present before the physical strain

If I understand Dr. Stephens aright he challenges the view that trauma may induce fibrillation, but as he does not do more than state his disagreement we must just leave it at that. He is, however, more articulate—although perhaps somewhat misleading—in his reference to Cases IV and V, as will appear evident from a careful perusal of our paper. His reference to "carious teeth and puffy inflamed gums" as conducive to auto-intoxication is interesting but irrelevant and has no direct bearing on the point at issue—namely, whether physical trauma is not in some cases a factor in the production of fibrillation of the auricles.—I am, etc.,

Liverpool, April 20th. JOHN HAY.

SIR,—Professor Hay and Dr. Wallace Jones have propounded two statements (March 26th, p. 559) for our acceptance. The first proposition is to the effect that sudden strain may induce auricular fibrillation in a diseased heart. I do not desire to quarrel with this statement, which is and always has been generally accepted.

The second statement is that strain may induce auricular fibrillation in an apparently healthy heart. What is the evidence which justifies such a sweeping assertion?

The exact pathological condition underlying auricular fibrillation is unknown. It is, however, a fact, based on an enormous amount of both clinical and pathological evidence, that wherever we find auricular fibrillation there we also find a damaged heart. The evidence, therefore, is that in order to induce fibrillation it is essential that the heart must be damaged beforehand. In face of this fact it is obvious that before it can be admitted that there are cases which do not conform to this rule it is imperative to make sure both that fibrillation did not exist before the trauma and that the heart is not damaged.

Case I we can at once exclude, because the factor which produced fibrillation is a great deal more than ordinary trauma. Case V may also be excluded, because in this case it is not disputed that the heart had already been damaged. In Case IV too we can assume that the heart had been damaged. The patient had a history of heart trouble and probably of fibrillation some years before fibrillation was again induced by trauma. In fact, this case seemed to be one of those frequently seen of paroxysmal fibrillation induced by overexertion which ultimately becomes chronic.

There remain only Cases II and III, on which the authors rely to support the thesis that fibrillation may be induced by trauma in an apparently healthy heart. In these two cases there is no evidence that the cases were not syphilitic—a Wassermann test is not mentioned. before the trauma. There is no evidence that the

A case of fibrillation came under my observation recently, supposed to have been produced by trauma, which gave a double plus (++) Wassermann reaction, and the patient ultimately admitted having had syphilis. Again, no particulars are given in these cases in regard to character of sounds, etc. Considering the difficulty of diagnosing myocarditis, these cases are not very convincing as evidence that trauma may induce fibrillation in an apparently healthy heart. But perhaps more curious still are the published electro-cardiograms. There are five electro-cardiograms published, taken from three patients. Fig. 1 shows extra-systole, preponderance of left ventricle, and a slurring of R. Now, extra-systole in itself is not of great importance, but when it appears in conjunction with fibrillation it usually signifies a damaged heart muscle. Fig. 5 shows right branch bundle lesion and extra-systole—denoting a grave condition of the myocardium. It will be seen that out of a total of three cases two are demonstrable by means of electro-cardiography alone to have had definitely damaged hearts. It is curious that the authors should rely on these cases to support their thesis that trauma may induce fibrillation in an apparently healthy heart.

There are a number of other statements in the paper in question which I should like to challenge, but I am afraid of trespassing too much on the space of your valuable journal.

To sum up, there is an enormous amount of evidence which goes to show that fibrillation appears only in conjunction with a damaged heart, and there has not been one shred of dependable evidence produced which would suggest that trauma may produce fibrillation in a healthy heart.—I am, etc.,

Liverpool, April 14th. I. HARRIS.

CERTIFICATION OF THE INSANE.

SIR,—Dr. Garratt (April 23rd, p. 779) asks for comments on the remarkable opinions expressed by consulting physicians during the hearing of the case of de Freville *v.* Dill. When convinced of the patient's insanity it is simply necessary to complete the Government form, carefully obeying the instructions printed thereon. When writing down the facts indicating insanity, it is well to remember that years after the medical man may have to stand in the witness box and be severely cross-examined as to the statements he has written down.

If the reports in the public press are correct, Dr. Russell is alleged to have said that the certifying physician should take the greatest care because his written opinion might

condemn a person to spend his whole life in an asylum. This, of course, shows a deplorable lack of knowledge of lunacy law and of the most efficient safeguards that exist to prevent the detention of a sane person.

As to the suggestion of Dr. Russell that the patient should be confronted with informants, little appreciation is shown of the difficulties that often beset the certifying practitioner, apart from the fact that it is no part of our business to convert a private house into a police court. As a very young practitioner I well remember being called to an hotel where a terrorized waiter gave me a vivid account of how he had been threatened with a revolver by an insane guest. On interviewing the patient I found him suffering from paranoia. As he was still in the possession of the revolver, had I confronted him with the waiter I should imagine a tragedy would have occurred.

During the course of the trial Dr. Hyslop, in reply to Mr. Singleton as to the correct course to be adopted when a raving patient threatens to kill one or more persons, is reported to have replied that the physician should send for nursing aid. Every general practitioner knows what would immediately happen—the nurse or nurses would be promptly shown out of the house.

It seems unfortunate that members of the profession should have to trust to the good sense of a judge to save them from the criticisms of their own colleagues.—I am, etc.,

London, W.1, April 22nd. ERNEST H. GRIFFIN.

TREATMENT OF CARCINOMA BY LEAD COLLOIDS.

SIR,—In the use of lead colloids for cases of inoperable cancer we cannot help feeling that there is far too much alarm lest any immediate reaction should follow such injections.

During the last few years we have given over 500 injections of various lead colloids, all made by the British Colloids, Ltd. At first certain of these caused considerable reaction, but it must be remembered that they were more or less experimental colloids, designed to provide a suspension of lead of not less than 0.5 per cent. which would keep permanently. The most recent colloids fulfil these demands, and in doses of 15 c.cm. they give no unpleasant reaction. The reaction is what is so badly called "protein shock" and exactly comparable in every way to a malarial seizure. Apart from any discomfort to the patient, we have never supposed nor have we found that they were in any way harmful.

The production of protein shock has been used as a therapeutic measure of great potency in many complaints. Cases of typhoid fever and pneumonia have been cured in twenty-four hours by its use. Other septic conditions and arthritis have been successfully treated by protein shock. One of us has treated severe cases of asthma by its use, injecting 50 to 100 million coliform organisms into the blood stream.

Of far greater importance is the avoidance of lead colic, vomiting, and other symptoms of lead poisoning. We have followed the teaching of Professor Blair Bell and avoided using such soluble salts of lead as the lead iodide. For this reason the present colloid we use is made in an atmosphere of hydrogen to avoid the possibility of the toxic lead hydroxide being formed.

Several colloids are now being made in which lead is combined with other metals and with organic bases. As it takes at least a year to form an opinion on the therapeutic value of any new colloid, the process is a slow one, but it is hoped that the great work which Professor Blair Bell has commenced may eventually lead to the discovery of some combination of lead that will be of the maximum therapeutic value.—We are, etc.,

FRANK COKE.
J. B. COOK.

London, W.1, April 25th.

THE OPERATION OF TONSILLECTOMY.

SIR,—May I be permitted to reply to the criticisms which appeared in your issue of April 9th (p. 702) anent my memorandum on "The operation of tonsillectomy," which was published on March 26th (p. 564). I quite agree with Mr. Whale that ambidexterity is a priceless asset in most things surgical, but my memorandum was intended to apply to tonsillectomy with the guillotine and mainly in relation to institutional work. I think most surgeons will agree that the guillotine is for obvious reasons the best instrument for that class of work; nevertheless, I am much obliged to Mr. Whale for his hints.

In reply to Mr. Horgan, I may say that I have not read the article he refers to as having been published in the *Practitioner* for August, 1925. What I had to say was an exact description of the method employed by me for many years, and was written in the presence of, and with the collaboration of, Dr. M. McLeod, who has anaesthetized the 3,000 patients mentioned. Further, as the removal of adenoids does not occupy more than about another five seconds, it seems scarcely worth while not to complete the whole operation before lowering the patient's head below the level of the operating table.

Such an incident as blood running down the larynx has never occurred in any of my cases, and I believe it is a bogy.—I am, etc.,

ALFRED J. S. ROE,
April 21st. Honorary Aural Surgeon, Hull Dispensary.

PATH OF INFECTION IN TUBERCULOSIS.

SIR,—I find that in your issue of April 23rd (p. 762), under "Reports of Societies," one or two slight inaccuracies have crept into the summary of my remarks at a meeting of the North-Western Tuberculosis Society on March 31st last. I hope that you will allow me to correct the few ambiguities to which I refer.

I am made to say that "in 'natural' tuberculosis the tuberculin test produced negative or slight reaction; in 'modified' tuberculosis there was a marked reaction." What I really said was "that 'natural' tuberculosis occurred chiefly in communities where the tuberculin test was negative in the majority of the population; whereas 'modified' tuberculosis tended to occur where the percentage of the population reacting to tuberculin tests was high."

In the sentence commencing "To sum up, the evidence was inconclusive," etc., what I really said was as follows:

"To sum up, the evidence could not be regarded as conclusive in either direction, but two things were certain—namely, that pulmonary tuberculosis was sometimes due to a reawakening of a previous infection; and, secondly, that the evidence pointed definitely to the danger of reinfection from outside, under certain circumstances, even in those already possessing a certain degree of acquired immunity. In such cases the tuberculosis due to the secondary reinfection would be of the ulcerative and chronic type."

Again, the sentence "Professor Cummins believed that both types of infection occurred" should have been as follows:

"While Professor Cummins believed that both paths of infection were capable of leading to pulmonary tuberculosis, he regarded it as certain that the respiratory path of infection was far the commonest cause of this type of tuberculosis, at least in man."

In discussing Bacmeister's experiments I did not say that they were unsatisfactory, but that they were not a certain proof that lymph stasis had been more operative at the apices than elsewhere, as the blood circulation as well as the lymph circulation was restricted.

The last sentence, referring to silicosis in coal miners, should have ended as follows:

"Professor Cummins found that in these latter men the lymphatic blockage led to a greater collection of coal dust at the apices than in other parts of the lungs, but the number of cases examined was insufficient to justify final conclusions."

I fully realize the difficulty of reproducing the exact words or even the exact sense of an address such as that delivered by me at Manchester. While paying every compliment to the reviewer, I think, however, that it is advisable to correct these few obscurities, as the question under discussion was one of considerable importance.—I am, etc.,

S. LYLE CUMMINS.

Cardiff, April 25th.

Obituary.

JOHN WHERRY WILLSON, L.R.C.P., M.R.C.S.,

Ex-Chairman of the Bradford Division of the British Medical Association.

DR. JOHN WHERRY WILLSON, who died on April 17th at the age of 59, received his medical education at Charing Cross Hospital, where he obtained the diplomas of M.R.C.S., L.R.C.P. in 1892. He began practice in Bradford some thirty years ago, and took an active part in the work of the British Medical Association and the Bradford Medico-Chirurgical Society. He was joint honorary secretary of the Bradford Division from 1909 to 1913, honorary treasurer from 1909 to 1919, and chairman in 1920. Upon his election to this last post he delivered an address entitled "Celebrated Yorkshire physicians," which contained many interesting historical references. He was a member of the Executive Committee of the Bradford Division from 1921 to 1923, and of the Division Ethical Committee from 1907 to 1909 and from 1922 to 1923. He was a member of the Yorkshire Branch Council from 1911 to 1912 and from 1920 to 1923. At the time of his death he was a member of the Executive Committee of the Harrogate Division. In 1924 he was elected president of the Bradford Medico-Chirurgical Society, and his inaugural address upon "Old Age" was considered a triumph of shrewd observation, apt quotations, and wise conclusions. Dr. Willson played a prominent part in the National Health Insurance controversy of 1911-12; and, from its inception until he left Bradford, he was a regular member of the Local Medical and Panel Committee. During the war his work as secretary of the Local Medical War Committee was of special excellence. He is survived by his widow.

A colleague writes: Dr. Willson was indeed the silver-tongued orator of the profession in Bradford. His flow of language, his clear enunciation, and his grasp of facts commanded the admiration of all. None of those who heard his address on "Meddlesome Midwifery" can forget the masterly exposition of his views, the statistical data, and the sagacious comments, all couched in beautiful phrases and delivered with easy grace and unchecked eloquence. He was a man of great literary and artistic taste and a wide reader, whose retentive memory made literature a joy to him. To his work in connexion with the Local Medical War Committee we largely owe the fact that in the area of the Bradford Division the task of fulfilling the Government's requirements proceeded so smoothly and with such general satisfaction. As a practitioner Dr. Willson gained the confidence of a large body of patients. He was a loyal and trusty colleague, a steadfast friend, and a very perfect gentleman. At the conclusion of his address upon "Old Age" he said: "Let us, with 'confidence born of the past,' meet the future with hope and good cheer, and with trust that whether our day end early or late, it may for each one of us be 'light at eventide.'" His last long illness was borne uncomplainingly, cheered by the hope that was in him.

DR. CAROLINE MATTHEWS, who died at Sydenham on April 16th, aged 49, received her medical education at the Edinburgh Medical College for Women, and graduated M.B., Ch.B.Ed. in 1903. Much of her professional life was spent on the Continent, and for her services in connexion with the Messina earthquake in 1908 she received King Victor Emmanuel's medal; in 1911 she was awarded the Italian Red Cross medal and King Victor Emmanuel's Commemoration medal. During the Balkan war of 1912-13 she acted as war correspondent to the *Sphere*, and held the rank of surgeon in the Montenegrin army, being awarded the Order of Danilo. At the outbreak of the last war Dr. Matthews joined the Serbian army, and when it retreated she remained in charge of the military hospital at Uzsitsi, being taken prisoner by the Austrians and imprisoned in Belgrade. After the war she spent much time in travelling, chiefly in India. Her publications included *Hints by a Lady Doctor* (1905) and *Experiences of a Woman Doctor in Serbia* (1916); she contributed an article entitled "In the hands of the enemy" to the *Sphere* in the latter year.

The following well known foreign medical practitioners have recently died: Dr. ANTONIO CARLE, professor of clinical surgery at Turin, aged 72; Dr. PERRIOL, director of the Medical School at Grenoble; Dr. LOUIS SCHNYDER of Berne, president of the Swiss Society of Neurology, aged 59; Professor HEVEROCK, a neurologist of Prague; Professor A. GILBERT, a leading Paris physician on the staff of the Hôtel-Dieu, joint editor of a system of medicine, and director of *Paris médical*; Professor FRIEDRICH GÖPPERT, director of the Pediatric Clinic at Göttingen; Dr. SALOMON EHRMANN, a Viennese dermatologist; and Dr. FRIEDRICH MERKEL, a gynaecologist at Nuremberg.

Medico-Legal.

PROSECUTION UNDER THE DANGEROUS DRUGS ACTS.

Definition of Legally Qualified Medical Practitioner.

THE stipendiary magistrate (Lord Ilkeston) at the Birmingham Police Court, on April 14th, inflicted a fine of £10, and £5 5s. costs, upon Alfred Arthur Austin of Edward Road, Moseley, Birmingham, on charges of attempting to obtain, and of being in possession of, dangerous drugs, he not being a person authorized or licensed in accordance with the Dangerous Drugs Regulations. Six further charges of being concerned in the supply of drugs on prescriptions signed by him to a Mrs. Ariss, since deceased, were dismissed on the ground that there was not sufficient evidence.

Mr. Joseph Edward Gascoyne, manager to Linells, Ltd., of Balsall Heath, stated that on five separate dates between 1922 and 1923 he supplied solution of cocaine to Mrs. Ariss on the defendant's prescription, and that in September, 1925, he personally supplied the defendant with a preparation containing morphine. The witness admitted that in March last he discussed with the defendant a recent prosecution of a person whose name had been removed from the *Medical Register*. The defendant seemed to be in doubt and had approached him in an inquiring spirit.

The defendant, in evidence, said he was qualified in 1887, being L.R.C.S.I. and L.A.H.Dublin, and on either of these qualifications he was entitled to practise surgery and medicine. He admitted that in 1913 his name was removed from the *Medical Register*, but he submitted that registration was not compulsory and he was not subject to any penalties for practising. The only drawback to not being registered was that he could not give death certificates which would be accepted by a registrar, and that he could not recover fees in a court of law.

Mr. P. W. Williams (the defendant's solicitor) argued that the defendant answered to the description of a duly qualified practitioner in accordance with the regulations and had committed no offence; but Mr. Pugh (the prosecuting solicitor) argued that under the Medical Act of 1858 to be duly qualified a medical man must be registered.

The stipendiary said he was satisfied that the defendant was not a legally qualified medical practitioner as he was not on the *Medical Register*. He would therefore fine the defendant £10, with the addition of £5 5s. special costs on the summons relating to being in possession of drugs.

The Services.

NAVAL VOLUNTEER DECORATION.

THE Royal Naval Volunteer Reserve Officers' Decoration has been conferred upon Surgeon Commander J. B. Ronaldson.

INDIAN MEDICAL SERVICE DINNER.

THE annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 15th, at 7.15 for 7.30 p.m. Major-General R. W. S. Lyons has been invited to take the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S. (ret.), 18, Nevern Mansions, Warwick Road, London, S.W.5.

DEATHS IN THE SERVICES.

Colonel Arthur Stephen, Bengal Medical Service (ret.), died suddenly at Ealing on April 22nd, aged 83. He was the son of Arthur Stephen of St. Cyrus, Kincardine, and was educated at Aberdeen, where he graduated M.A. in 1864, and M.B. and C.M. with honours in 1867. Immediately after graduation he entered the I.M.S. as assistant surgeon, passing into Netley first. He attained the rank of surgeon colonel on May 17th, 1894, and retired on May 19th, 1899. He served in the Abyssinian campaign of 1868, receiving the medal, but spent most of his service in civil employment in the Punjab, the last five years as Inspector-General of Civil Hospitals in that province.

Fleet Surgeon William Frederick Spencer, R.N. (ret.), died at Forest Hill, London, on April 15th, aged 79. He was educated at the Carmichael School, Dublin, and at Queen's College Galway, graduating M.D. and M.Ch. of the Queen's University, Ireland, in 1872. Soon after, he entered the navy as surgeon, and attained the rank of fleet surgeon on July 2nd, 1893. He served as surgeon of H.M.S. *Thalia* in the Egyptian war of 1882, and received the medal and the Khedive's bronze star.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons reassembled on April 26th, when the Budget resolutions were discussed on the Report stage. The additional patent medicine duty resolution proposed that the additional excise duty imposed by the Finance Act of 1915 should be made permanent. An amendment, in the names of Sir R. Hamilton, Mr. Harris, and Mr. Duckworth, limiting the effect of the resolution, was ruled out of order. Lieut.-Commander Kenworthy urged that as poor people, who could not afford a doctor, bought patent medicines, the duty would be a tax on the sick and ailing poor.

Mr. McNeill said that the income from the duty last year was £1,340,000, a sum not to be despised in a time like the present. The additional duty was being made permanent, because experience had shown that these commodities could well bear the tax without decreasing their consumption. Since 1915 the yield from this duty had gone up nearly four times. Last year an interdepartmental committee had considered whether any better and more convenient form for the definition of the tax could be found, but recommended that the charging words under the old statute were really as useful, for the purpose in view, as any that could be put in their place. The tax was originally, and still was in principle, a tax on quack medicines. No real medicine recommended by a qualified medical practitioner, or which, coming under certain definitions, was supplied as ordinarily part of the *British Pharmacopœia* by druggists, came under the tax at all. The resolution was carried.

On the following days debate on the Budget was continued.

Universities and Colleges.

UNIVERSITY OF LONDON.

LONDON HOSPITAL MEDICAL COLLEGE.

A LECTURE on recent medical and dental research on accessory food factors in relation to diseases of the teeth will be given by Dr. J. Sim Wallace at the London Hospital Dental School on Monday, May 9th, at 5 p.m. Members of the profession and medical and dental students of the hospital are invited to attend.

UNIVERSITY OF BIRMINGHAM.

UNDER the William Withering memorial lectureship a course of ten lectures on organic inheritance in man is being delivered by Dr. F. A. E. Crew, F.R.S.E., in the large theatre of the medical school buildings of the University of Birmingham. The first was delivered on April 27th and the last will be given on June 2nd. Members of the medical profession are invited to attend. Admission cards can be obtained on application to the Dean.

UNIVERSITY OF GLASGOW.

THE following degrees were conferred on April 23rd:

M.D.—*R. L. Mackay, †D. M. Lindsay, †J. Lindsay, Grace M'Lintock, P. O. Moffat.

CH.M.—*J. R. Learmonth.

B.Sc. (*in Public Health*).—R. L. Leask.

M.B., CH.B.—The degrees of M.B., Ch.B. were conferred upon the 57 successful candidates whose names were published in our issue of April 16th (p. 748).

* With high commendation.
† With commendation.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examination indicated:

FINAL EXAMINATION.—*Medicine*: V. H. L. Barlow, J. G. Buchanan, Velarkar, B. F. Lewin, A. C. Lovett-liveiro, S. K. Ponniah, S. T. Sodah, M. M. Fargkaly, G. R. Gardner, Alice Law, D. F. Lewin, F. M. K. Logan, Dorothy J. O. Mitchell, W. B. Russell, M. M. Wright. *Midwifery*: E. P. N. Abeyesundere, G. R. Day, A. S. Gordon, Alice Law, P. M'K. Logan, A. C. Lovett-

Of 86 candidates entered, the following passed the Final Examination and have been admitted L.R.C.P.Ed., L.R.C.S.Ed., L.R.F.P. and S.Glas.:

Rosie Swamikan, J. J. Craig, J. Williams, V. Nath, T. G. Macintyre, M. Clayton-Mitchell, J. Hall, A. B. Paul, A. B. Gilston, K. Dhar, J. S. Fernando, H. A. Erickson, O S. Crowth r, V. Doraisamy, W. O. M'Laren, J. Gilchrist, O. Dawood, K. S. Rao, J. T. Amarasingham, M. Ponnambalam, W. J. Cudahy, A. Lipschitz, K. Cathinvelu, J. P. M. Donnelly, Elizabeth Bell, D. S. Johnston, T. de Silva, E. Kramer, R. Abrahams.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicate

SURGERY.—L. G. Apps, P. Brookes, W. H. Collins, A. F. J. D'A W. Howard, S. B. S. Smith, L. Wasef.

MEDICINE.—D. K. Reynolds, S. K. Rigg.

FORENSIC MEDICINE.—J. Bramall, C. M. Brooks, J. A. Fernandez, W Neill, D. K. Reynolds.

MIDWIFERY.—P. Brookes, R. P. Charles, W. Howard, H. S. Ma B. Rosenzvit, S. B. S. Smith, M. A. Yousef.

The diploma of the Society has been granted to Mr. L. G. A

Medical News.

A MEDICAL congress under the name of Journées Médic d'Egypte, organized by *La Revue des Maladies des I Chauds*, will be held at Cairo this year from December to 24th, under the joint presidency of Professors J. L. Fa and A. Loutfi el Sayed. The vice-presidents are Profes Andrew Balfour, Aldo Castellani, and J. W. W. Steph Various diseases of temperate and warm climates will dealt with, including liver abscess, bilharziasis, trypa somiasis, Oriental sore, leprosy, kala-azar, trachoma, mala yellow fever, and Malta fever. French and English wil the languages used for the congress. It will consist of following sections: ophthalmology, of which Colonel R. Elliot is president; medicine, surgery, urology, gastro-enterology, hygiene, dermatology, diseases of the ear, nose obstetrics, neurology, tuberculosis, and veterinary medici There will be an international exhibition illustrating application of science to medicine, surgery, pharmacy, hygiene. In connexion with the congress special terms be obtainable from steamship and railway companies. Furth details about the congress may be obtained from the gene secretary, Dr. Zeitoun, 32, rue Gay-Lussac, Paris, Ve., whom notice of papers to be contributed should be sent befo October 1st.

THE St. Mary's Hospital Institute of Pathology and Researc has arranged a course of lectures on pathological research its relation to medicine, to be given during the summ session on Thursday afternoons at 5 o'clock. The first, May 5th, will be by Professor Carl Prausnitz, of the Institu of Hygiene, Breslau, who will deal with the bacteriophag The second (May 12th) will be given by Dr. R. A. O'Brie Director of the Wellcome Physiological Research Labor tories, who will discuss streptococci, their toxins and ant toxins; the third (May 19th), by Lieut.-Colonel S. P. Jame M.D., I.M.S., Adviser on Tropical Diseases to the Ministry Health, will be on malaria research; the fourth (May 26th by Professor Hugh Maclean, on insulin; the fifth (June 2nd by Professor Lovatt Evans, M.B., F.R.S., of Universit College, on the alkalinity of the blood; and the sixth (Jun 9th), by Professor B. J. Collingwood, on the molecula movement in the living blood. The lectures are open to a members of the medical profession and to all students i medical schools without fee.

THE Fellowship of Medicine announces that Mr. Goulde will give a demonstration at the Royal London Ophthalmi Hospital on May 3rd at 1 p.m.; this demonstration is free t medical practitioners. A series of clinical and cytoscopi demonstrations will be given at the All Saints' Hospita Vauxhall Bridge Road, S.W., from May 2nd to 28th, and o each Wednesday during the four weeks a special lecture wi be delivered at 2 p.m. The Maudsley Hospital will hol during the same period an afternoon course in psychologica medicine, including demonstrations of the pathology of menta diseases, clinical psychiatry, and the psychoneuroses. Fro May 4th for four weeks there will be a course at the Londo Lock Hospital, comprising clinical teaching and a series lectures. On successive Wednesdays from May 4th to 25t inclusive Professor McIlroy will give lecture-demonstration on ante-natal diagnosis and treatment. An intensive cours will be arranged at the Central London Throat, Nose, an Ear Hospital from May 9th to 28th, covering all departmen of laryngology, rhinology, and otology; as the entry for th operative part of the course is limited early application desirable. From May 9th to July 15th the National Hospita Queen Square, will hold a course comprising clinical lecture and demonstrations, teaching in the out-patient department pathological demonstrations and lectures, a course in anatom and physiology, and one in methods of examination. Com mencing on May 16th a fortnight's course will be held at th Hampstead General Hospital; it will consist of medical surgical, and specialty demonstrations primarily for genera practitioners. Copies of all syllabuses, the general conr programme, and of the *Post-Graduate Medical Journal* a obtainable from the Secretary of the Fellowship, 1, Wimpol Street, W.1.

A SPECIAL course in infants' diseases will be given at the Infants Hospital, Vincent Square, on the afternoons of May 16th to 28th, for medical officers of welfare centres and those who are interested. In addition to lectures, round table consultations, and clinical demonstrations, visits will be paid to a model pasteurizing plant, a venereal diseases centre, and homes for infants. The fee for the course is three guineas, and those wishing to attend should send early notification to the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1, since the course is limited to fifteen.

AT the quarterly meeting of the Welsh National Memorial Association at Chester last week certain reports on the Spahlinger treatment were presented. The medical committee expressed the view that the published records and statistics of cases treated by the Spahlinger remedies were not nearly complete or precise enough to allow of a scientific estimate of the results obtained. On the whole the committee were of opinion that they were disappointing. The remedies, it was said, did not offer a "certain" cure for tuberculosis, and conclusive evidence had not been forthcoming that they had materially altered the course of the disease. The committee did not recommend the application of public or other funds to the Spahlinger Institute.

A COURSE of lectures and demonstrations in surgical urology will be held at Necker's Hospital, in Paris, from June 8th to 18th. It will include practical work on the cadaver and the use of instruments. The inclusive fee is 1,000 francs, and further information may be obtained from Dr. Fey, 151, rue de Sèvres, Paris.

THE British Social Hygiene Council will hold a summer school at Keble College, Oxford, from August 3rd to 9th. A course of lectures on biology and social hygiene will be given by Professor J. Arthur Thomson, and one on psychology and social hygiene by Dr. H. Crichton Miller. Further information may be obtained from the secretary of the British Social Hygiene Council, Carteret House, Carteret Street, S.W.1.

IN aid of the rebuilding fund of the Royal Westminster Ophthalmic Hospital a luncheon will be held at the Savoy Hotel on May 4th, when the prospects of the hospital will be described by the Earl of Clarendon, Sir Richard Cruise, and others.

THE new laboratories of the Metropolitan Asylums Board at Park Hospital, Hither Green, S.E.13, will be opened by Mr. Neville Chamberlain on May 9th, at 3.15 p.m. These laboratories will be the headquarters of the Board's research and pathological work.

SIR BERKELEY MOYNIHAN, Bt., P.R.C.S., has been appointed a Deputy Lieutenant of the West Riding of the County of York and of the City and County of the City of York.

WE are asked to state that correspondence for Professor Lyle Cummins should in future be addressed to the Tuberculosis Department, Institute of Preventive Medicine, The Parade, Cardiff.

THE newly formed South Wales Medical Golfing Society will hold its first meeting at the Southerndown golf course on Thursday, May 5th, when play will take place for the Alfred Miles cup. All medical men in South Wales (comprising Glamorganshire, Cardiganshire, Carmarthenshire, Pembrokeshire, and Breconshire) and in Monmouthshire are eligible. The competition for the Treasurer's Cup of the British Medical Association will take place at the same time among members of the Cardiff, North Glamorgan, and Brecknock Divisions; the final stage of this competition, it will be remembered, is to be played at the Annual Meeting of the British Medical Association at Edinburgh on July 22nd. Full particulars can be obtained from Dr. T. Garfield Evans, 127, Cathedral Road, Cardiff.

THE final of the Medical Golfing Society's knock-out tournament was won by J. Cunning, the runner-up being E. Playfair.

IN view of the proposed new motor legislation the Automobile Association recently addressed a series of questions to motorists throughout the country. Replies were received from nearly 100,000. Ninety-seven per cent. were in favour of reverting to a petrol tax in place of the present taxation based on the horse-power of cars. The abolition of the twenty-mile speed limit was supported in 92 per cent. of the answers received; 81 per cent. favoured the abolition of ten-mile limits. In various questions of smaller importance the percentage was about the same. The highest percentage—98—was in favour of special legislation to penalize the joy-rider; from which it would seem that many motorists must have suffered from this irresponsible person.

PROFESSOR HERMANN LUDWIG WINTZ, director of the gynaecological clinic at Erlangen, has been invited by the Radiological Society of North America to deliver addresses before several American universities on the *x*-ray treatment of carcinoma.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863, and 9864* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

"A SUFFERER" from cold and clammy hands asks for advice.

HABIT-SPASM IN A CHILD.

DR. JULYAN HOYTE (Elisabethville, Katanga) asks for suggestions as regards the prognosis and treatment of intractable habit-spasm in a little girl, aged 2½. When put to bed the child very often raises herself into the knee-elbow position and commences to sway her body backwards and forwards, the head striking the pillow sharply at each forward swing. She repeats this for two or three seconds for long intervals, sometimes continuing it for two hours, with brief rests, before falling asleep. Occasionally she goes to sleep normally, but rouses later to perform the bumping process. Punishment at the time seems to have no effect, but if administered during the next day it has some deterrent action. In other ways the child is normally developed, though rather slow in talking, a characteristic frequently noticed in the children of Europeans in the neighbourhood who grow up bearing two langnages spoken. She has had two severe attacks of malaria, both accompanied by convulsions, but the first occurred some time after the habit-spasm commenced, which was about the age of 6 months.

READING FOR THE BLIND.

"J. A. H." wishes for information regarding the teaching of Braille type for the blind.

*** A child of school age would be taught this script at some school for the blind carried on by or with the co-operation of the local education authority. Under the Education Acts the local education authority is responsible for this, and now also for the training of blind persons over school age. For an independent person wishing to learn Braille the best way to obtain the necessary information and equipment would be to apply to the National Institute for the Blind, Great Portland Street, London, W.1. The Institute will supply instruction books, writing boards, and so forth. It has local branches through which the learner can arrange for "home teaching" by approved teachers. The Institute issues Braille-printed newspapers and literature suitable for the general reader and the serious student.

THE CHEWING OF GUM.

DR. W. W. HARDWICKE (London) writes: In reply to Dr. W. J. Burns Selkirk (JOURNAL, April 9th, p. 703), there can be no analogy between the normal and the abnormal. The desire to suck in the infant and the chewing of the cud in the cow are normal acts. The chewing of gum (wax) in the human youth or adult is not normal, but an acquired and disgusting habit, similar to the desire in the greedy to be continually gratifying the palate by eating or drinking. All bad habits have a soothing effect, or they would never have existed, but this fact does not justify their existence, or do away with the bad effects of them—in this instance the premature wearing out of the overworked salivary glands. The overstrain of these glands must tend to shorten their lives of usefulness, resulting ultimately in digestive trouble, and the hypertrophy of the masseter muscles, in an ugly deformity of the cheeks.

INCOME TAX.

Deduction for Surgery.

"E. H." now uses solely as a surgery a house in which he formerly resided. A woman, with her husband and one child, lives there and acts as caretaker. She receives no wages, but lives free of rent, rates and gas, coal and electricity.

*** "E. H." can deduct the whole cost of rent, rates, light, and heat as a professional expense, but not, of course, any expense borne *by the caretaker* in keeping the premises clean.

Car Replacement and Basis of Assessment.

"R. P." bought car A in June, 1925, for £140 and sold it in May, 1926, for £90, buying car B for £125; he commenced practice as a consulting physician on his own account in October, 1924; can he claim the benefit of the three years' average?

*** He should claim, as an expense of the year 1926–27, £125–£90=£35 obsolescence allowance, and for the year 1927–28 a depreciation allowance of 20 per cent. of £125—that is, £25. The assessment for the period October, 1924, to April, 1925, should be on the basis of the actual earnings, for the year to April 5th, 1926, on the earnings of his first year, for 1926–27 on the average of the earnings of his first two years, and for 1927–28, when the average basis disappears, on the basis of the earnings of 1926–27.

LETTERS, NOTES, ETC.

DEATH BY LIGHTNING STROKE.

DR. ESPINE F. WARD, *of the West African Medical Staff*, sends particulars of the death from lightning on November 24th, 1926, of fourteen native women, whose ages ranged between 15 and 35. Some four hours after the accident he found the women lying dead in the village market place under a light shelter, which consisted of a few uprights supporting a galvanized iron roof 5 ft. 6 in. high. One other woman, who showed signs of life but was unconscious, was transferred to hospital twelve miles away, and subsequently made a good recovery. She left hospital *twenty-four hours later of her own accord, complaining*, however, of pains in her legs, giddiness, and difficulty in walking, but was *unwilling to remain longer under treatment*. Two other women, who had also been of the party, had already recovered, and were apparently none the worse, except for vague general pains.

Dr. Ward writes: "I was told that one of the dead women had had her six months old baby strapped on her back; after her death the baby had been rescued by friends and was none the worse for the ordeal, but I did not see the baby nor could I get any further particulars about it. The light shelter was about 12 ft. square and the women had been seated in a circle on the ground, looking inwards. All the bodies were found lying on their backs, evidently having fallen backwards after the shock, their feet pointing inwards. *The position of the bodies was very much the same in all cases, although one or two had evidently* fallen against one another when killed and lay across each other. In all cases the pupils were widely dilated and rigor mortis had set in; the clothes of all were wet, but showed no signs of injury, and the ground around was soaked by rain, the women lying in puddles of water. There were no signs of burning or of any injuries on the bodies, and although all of them had sums of money in coin tied in their waistbands, the coins were not *affected. Five of them had frothed* at the mouth; in several cases the hands were clenched and the arms flexed. No *post-mortem* examinations were made. I was informed that heavy rain had fallen during the afternoon; it was not possible to say whether the lightning occurred during the rainstorm or preceded *it. When the women were seen to be apparently dead the* people in the market all ran away; some returned later, and it was then seen that the two women were recovering. They were then unable to walk and were carried away by their friends. Nothing was done for the rest, although it transpired that one had shown signs of life. I think it is highly probable that many others might have been saved also if first aid had been available sooner, but, left as they were in their wet clothes on the wet ground, the opportunity had passed. The market is on laterite soil, *about seventy yards square, covered with little shelters and* with many trees scattered about; it probably contained some three hundred people at the time of the accident. No trees were more than 30 ft. high. Neither the shelter itself nor any of the trees showed any signs of having been struck. The bodies were removed to the mortuary in a motor lorry. *The driver refused* to drive the lorry, as there was a prevalent belief that anyone removing the bodies before the 'juju' had been appeased by a ceremony of purification by the 'thunder women' would die within a week. However, the European manager of the local transport company drove the bodies to the mortuary, in spite of the warnings he also received. Three days later he was admitted to the European hospital at Accra and died on the Tuesday evening following from yellow fever, after three days' illness. This strange coincidence admits of only one explanation to the native mind.

"It is difficult (Dr. Ward adds) to advance any theory how the electrical discharge caused these fatalities, because the natives were very reluctant to *give information of what they regarded* as a powerful 'juju' (afterwards so unfortunately confirmed in their minds by the death of the driver). The whole circumstances provide another instance of the peculiarity of lightning, and I suggest that in this case these fatalities were due to the people forming the opposite pole of [illegible] iron, which had become highly cha[illegible] storm broke; they thus provided p[illegible] particulars are given with the kind permission of the Director of the Medical and Sanitary Services."

THE OPERATION OF TONSILLECTOMY.

DR. PATRICK LEIGHTON (Mottingham) writes: I have read with much interest the letters recently published on ambidextrous enucleation of tonsils with the guillotine.

For years, in over 2,000 cases, I had used both hands, using the forefinger of one to push the tonsil through the ring, but after accidentally buttonholing the palate and removing the skin of the end of my own finger, it occurred to me to use the thumb, with far better results. The reason was that the thumb, being larger, did not penetrate the ring. The anaesthetist should be armed with a swab on a sponge forceps, which is pressed into *the cavity for a few seconds the moment the tonsil is removed.* In this way a clear view of the other tonsil is *obtained.* A Sluder Ballenger guillotine No. 1, made by Gardner of Edinburgh, gives me every satisfaction.

The above remarks refer to ethyl chloride anaesthesia, when the complete operation should take about 25 seconds. I agree with Mr. H. L. Whale that both hands should be used in the dissection operation.

SMALL-POX AND VACCINATION.

LIEUT.-COLONEL A. BUCHANAN, M.D., I.M.S.(ret.) (St. Jacques, Guernsey), in the course of a communication on this subject, writes: When a bad attorney has a weak case he sometimes sets up a false issue, and then proceeds to "knock the bottom out of it." In a similar way Dr. Killick Millard shows (JOURNAL, February 12th, p. 306) that the occurrence of 6,000 cases with 500 deaths—I am giving round figures—in a city where 98 per cent. of the population had been vaccinated *is a proof of* the unreliability of infant vaccination to protect the community. But no one has, as far as I am aware, asserted that infant vaccination affords lifelong protection. Dr. Millard himself stated in the same paragraph that *it has been* conclusively proved, over and over again, that vaccination confers temporary protection upon the individual. It follows that if all individuals in a city were vaccinated and revaccinated the community would be protected. Professor Wynne had shown (February 5th, p. 261) that the great majority of those who had been attacked, although "officially vaccinated," were actually unprotected by vaccination. Professor Wynne pointed out that "modern measures" had failed, and Dr. Millard thinks that it is a little too early to abandon hope, for he finds that in three weeks in January there were not more than 277 cases of small-pox in Sheffield. It would be interesting to know how many cases would have to occur before Dr. Millard would resort to the method of protection which he admits has been conclusively proved, over and over again, to confer temporary protection.

A WARNING.

DR. C. B. MOSS-BLUNDELL (county medical *officer of health*, Huntingdon) writes: It is reported to me that a man who may give the name of Dr. Winter has been calling on professional men, particularly doctors and accountants, soliciting help. He may describe himself as an accountant and may say that he is an old Rugby and Oxford man, and has acquired a certain amount of information about these two places. He suffers from pulmonary tuberculosis and may state that he has been at Yardley Road, Lenham, or Papworth Sanatorium, the latter statements being true. He has lately been "working" the Oxford-Slough area. He is about 33, height 5 ft. 5 in., of spare build, with bushy eyebrows, and rather penetrating downcast eyes. When he left this district he was dressed in a dark grey suit and Trilby hat. I should advise *doctors* to take necessary precautions should he call on them.

SPINAL ENDOTHELIOMA.

MR. J. R. LEARMONTH (Glasgow) writes with *reference* to the note on his paper on spinal endothelioma, published in our issue last week (p. 768), to state that "the work on the transplantation of the cerebral vesicles of *Amblystoma punctatum*, to which you refer *in your notice of my paper on spinal* leptomeningioma, was carried out, not by Harrison, but by *Professor S. C. Harvey* and Dr. H. S. Burr of Yale University (vide *Arch. Neurol. and Psychiat.*, 1925)."

A CORRECTION.

IN Mr. Duncan C. L. Fitzwilliams's article on page 758 *of the* BRITISH MEDICAL JOURNAL the last word in the second paragraph should have been "iodide," and not "iodine."

VACANCIES.

NOTIFICATIONS *of offices* vacant in universities, medical colleges, and of vacant resident and other appointments at *hospitals*, will be found at pages 37, 38, 39, 40, 41, 44, and 45 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement at page 187.*

A British Medical Association Lecture

ON

UROGENITAL TUBERCULOSIS.

GIVEN TO THE SOUTH-WESTERN BRANCH

BY

C. A. R. NITCH, M.S., F.R.C.S.,

SURGEON TO ST. THOMAS'S HOSPITAL, LONDON.

THERE was a time when urogenital tuberculosis was regarded as a more or less hopeless disease, and the unfortunate sufferer was condemned to a life of misery interspersed with courses of tuberculin, cod-liver oil, and sanatorium treatment, until, worn out by painful and frequent micturition, and wasted to a shadow by toxaemia, death put an end to his sufferings.

Within recent years research in the laboratory and in the *post-mortem* room has revealed the true pathology of the disease, and this knowledge, combined with the perfection of the cystoscope, has enabled the clinician to make an accurate and often an early diagnosis, and by means of active surgical treatment to give the patient a good prospect of complete recovery. But even now the ultimate mortality is still too high, and the reason is not far to seek. Successful treatment in this, as in all other diseases, depends on an early diagnosis, but unfortunately very few cases reach the surgeon before the signs and symptoms are unmistakable. Therefore, at the outset I want to emphasize the importance of a thorough clinical and bacteriological examination in all urinary cases, particularly those with intermittent bladder irritation and so-called cystitis. The following is a case in point.

A stout, healthy looking woman, aged 49, dislocated her shoulder; a week later micturition suddenly became frequent and painful. This was diagnosed as cystitis, treated with an alkaline mixture, and soon subsided. A recurrence four weeks later led her to seek further advice. Cystoscopy revealed slight congestion around the right ureteric orifice. Both ureters were catheterized. Urine from the left was normal; that from the right contained a few pus cells and a number of tubercle bacilli. The right kidney was removed and found to contain a small tuberculous focus in its lower pole. Six years later she was in perfect health and the urine was normal.

In discussing urogenital tuberculosis it is most convenient to commence with the kidney, for disease of this organ forms a large proportion of the cases of urinary tuberculosis; also a lesion in the kidney is very commonly the primary focus from which the lower urinary and the genital tracts are directly infected.

RENAL TUBERCULOSIS.

It is now well known that tubercle bacilli reach the kidney from some other focus in the body, either a quiescent and obscure lesion such as a tuberculous mediastinal gland or an active and obvious source such as pulmonary, articular, or osseous tuberculosis. These two sources of infection, generally speaking, give rise to two distinct clinical and pathological types of renal tuberculosis, called surgical and medical respectively. Though this is the usual rule, statistics show that in about 25 per cent. of cases the surgical form is secondary to *active* pulmonary and pleural tuberculosis.

Surgical or chronic renal tuberculosis was once thought to be primarily unilateral, but animal inoculation has now shown that a few early cases are bilateral. It is characterized by caseation, ulceration, and slow but progressive destruction. The urine contains tubercle bacilli, pus cells, caseous material, fragments of renal tissue, and a small trace of albumin of pyogenic origin.

The *medical* form is bilateral, the renal parenchyma is studded with miliary tubercles and the urine is clear, containing a few bacilli, many hyaline and granular casts, and a large trace of albumin. It is accompanied by typical physical signs of chronic nephritis and often ends in uraemia. Therefore the presence of tubercle bacilli in the urine does not necessarily imply that surgical treatment is required, but it does call for a careful and exhaustive examination. A kidney urine containing tubercle bacilli and pus cells demands immediate surgical treatment.

It is difficult to account for the two widely different pathological types, but probably the difference is only one of degree. In the miliary or medical form bacilli and toxins from an active lesion such as pulmonary tuberculosis are constantly passing through the kidney. Many of the bacilli are undoubtedly excreted in the urine, but eventually their escape is prevented by endarteritis and chronic nephritis; they therefore lodge in the glomerular zone and give rise to multiple tubercles. At this stage death takes place before caseation and liquefaction can occur. In the surgical form the kidney receives from a quiescent focus an occasional tuberculous embolus which becomes isolated by a barrier of protective inflammation. This is followed by the formation of a tuberculous abscess which either increases at the expense of the surrounding parenchyma or discharges into the renal pelvis.

CHRONIC RENAL TUBERCULOSIS.

As the miliary form is part of a general disease, and so not amenable to surgical treatment, my future remarks will apply to chronic or surgical renal tuberculosis.

Paths of Infection.

Tubercle bacilli reach the kidney either by the blood stream or by the lymphatics, and of these two routes the haematogenous is undoubtedly the commoner. The exact site of the initial lesion in the kidney is disputed. The peculiar arrangement of the intrarenal arteries favours a cortical lesion, but clinically, though many tubercles are seen in the cortex, the grossest lesion is nearly always at the base of a papilla.

The lymphatics are considered by some to be the means of infection in those cases which are secondary to quiescent pleural and pulmonary tuberculosis. The bacilli are thought to be carried in the lymphatics passing through the diaphragm by a retrograde current set up by pleural adhesions. Though primary lymphatic infection is doubtful, secondary infection may be conveyed from a diseased to a healthy kidney by the communicating channels between the two renal plexuses, or from an ulcerated bladder by the peri-ureteral lymphatics.

Ascending infection up the lumen of the ureter does not occur. Animal experiments by English and Continental workers have proved (1) that pyogenic and other organisms placed in the bladder cannot pass the normal uretero-vesical valve, and (2) that when pyogenic organisms are injected into the ureter and pelvis the renal papillae prevent their entry to the kidney.

An ascending infection can only occur when the mucous membrane of the bladder or ureter is damaged, and it then travels in the wall of the ureter or in the peri-ureteral lymphatics. In all probability ascending tuberculous infection seldom occurs, for even when all the essential factors are present in the form of advanced genital and vesical tuberculosis the blood stream as a vehicle can never be discounted.

The pathological anatomy of the disease is so intimately connected with its clinical aspect that a brief description is essential for a proper understanding of the symptoms and treatment. Three types are recognized.

I. *Primary closed parenchymatous tuberculous nephritis* consists of one or more encapsuled foci in the parenchyma which progress to caseation and abscess formation and ultimately destroy the whole kidney. This is accompanied by an interstitial inflammation of the pelvis and calyces, ending in the formation of fibro-fatty tissue which fills the pelvis and excludes a portion or the whole of the kidney and its tuberculous products from the urinary tract. This process is called spontaneous cure, or auto-nephrectomy. The term is misleading, for it suggests that the disease is arrested or removed, but this is not the case. The bag of fibro-fatty caseous material never disappears; it may remain inert for years, but sooner or later the disease either invades the perinephric tissues or is disseminated to other parts of the body through the blood stream. The clinical signs of this condition are characteristic. In its early stage the urine of the infected kidney is increased in quantity, its specific gravity is lowered, and it contains a trace of albumin and a few pus cells. It is sterile and seldom contains tubercle bacilli. The renal function is

defective when compared with that of the opposite side. As destruction and exclusion progress the secretion of urine diminishes and finally ceases. The patient complains of frequency and vesical irritation, which is often diagnosed as mild cystitis and treated medicinally.

II. *Primary open tuberculous pyelonephritis* is characterized by ulceration of the pelvis combined with progressive destruction and ulceration of the papillae and parenchyma. There may be deeper lesions and miliary tubercles in other parts of the kidney, but the condition is essentially a tuberculous pyonephrosis. The changes spread down the ureter, its mucous membrane becomes ulcerated and its walls thickened. Its vesical orifice is wide open and dragged out, and the surrounding mucosa is ulcerated and sometimes studded with tubercles. The clinical picture is one of painful frequency (pollakiuria) with pyuria and occasional haematuria. The urine from the affected side contains pus, caseous material, renal elements, blood cells, and tubercle bacilli in large numbers. Often, the efflux from the ureteric orifice resembles tooth-paste emerging from a collapsible tube.

III. The third type consists of a combination of the open and closed varieties. Its clinical features are similar to those of the second type.

Clinical Signs.

The clinical signs seldom indicate the extent of the lesion. The affected kidney may be enlarged, irregular, and tender, but enlargement is unusual. The ureter is often thickened, and can be readily felt as a firm, round, tender cord on bimanual examination—rectal in the male and vaginal in the female. It is unfortunate that thickening of the ureter should have come to be regarded as a diagnostic sign of renal tuberculosis, for it indicates long-standing disease. It is to be hoped that in the near future an accurate diagnosis of the renal lesion will be made long before the ureter has become thickened. The opposite kidney is very often enlarged and tender from compensatory hypertrophy and toxic nephritis. In this context it is interesting to note that the urine from the healthy kidney often contains albumin, which disappears after removal of the diseased kidney.

Cystoscopic examination may show the bladder to be inflamed and ulcerated, or the trigone alone may be congested. The appearance of the ureteric orifice is often the only visible sign of the hidden focus in the kidney. It may be congested or oedematous, or surrounded by minute bullae. There may be tubercles on its lips, or it may be surrounded by a ragged ulcer with tubercles on its margins. In long-standing cases the orifice is wide open, rigid, and ulcerated, and when there is much thickening and fibrous contraction of the ureter the bladder is dragged out, forming a small hollow cone with the ureteric orifice at its apex. The efflux may be forcible and clear, or turbid, or even putty-like, when it appears like a worm-cast, which curls up as it is ejected and falls to the bottom of the bladder. When the orifice is open and rigid, turbid urine trickles out in a slow, continuous stream, or a ragged mass of caseous material is slowly forced out. Absence of efflux indicates obstruction of the ureter by caseous material or complete exclusion of the kidney.

Symptoms.

The symptoms are essentially those of cystitis—pain, frequency, pyuria, and occasionally haematuria. They commence gradually and increase steadily. Sometimes the onset is sudden. This is due to the escape of tuberculous products from a focus in the kidney which has suddenly ruptured into the pelvis, giving rise to bladder irritation and frequent passage of turbid acid urine. In a few days the cavity in the kidney closes, the symptoms subside, and both patient and practitioner are lulled into a false sense of security. After an interval, during which the cavity refills, the process is repeated and the symptoms recur. These intermissions may last for months or years, the intervals of freedom becoming progressively shorter, until finally the discharge from the kidney becomes continuous and the lower urinary tract grossly diseased.

Pain.—The kidney may ache, but it is seldom painful. In rare instances there are definite attacks of colic, due to the passage of caseous material or blood-clot. In some cases pain is felt only in the healthy kidney, when it is probably reflex, for it disappears after removal of the diseased organ. The pain of cystitis is felt at the neck of the bladder, along the urethra, and in the perineum.

Frequency is at first due to trigonal irritation and later to cystitis. In the beginning it is diurnal only, soon becomes nocturnal as well, and finally merges into total incontinence. Nocturnal frequency is one of the most constant and important symptoms of the disease.

The changes in the urine have already been described but there are certain features which require further consideration. Polyuria, due to a defective renal function is present from the commencement, and is replaced by oliguria as the kidney is destroyed. Albuminuria can be accounted for by pus and blood from the diseased kidney and by toxic nephritis on the opposite side. In the latter case it is often associated with hyaline and granular casts. Haematuria is a variable symptom. A profuse haemorrhage may be the first indication of the disease; as destruction progresses there may be slight haemorrhages at long intervals, or there may only be an occasional microscopic trace of blood.

The presence of tubercle bacilli in the urine is, of course, the only definite diagnostic sign. When found in a clear urine they are either being excreted by a normal kidney or by one containing miliary tubercles, but when a urine obtained by catheterization of the ureter contains both tubercle bacilli and pus cells there can be no doubt that the kidney is the seat of a surgical lesion.

When a secondary infection is present colon bacilli and other pyogenic organisms may be found in the urine, and may mask the true nature of the disease. The smegma bacillus should not cause an error in diagnosis, for it can now be identified by careful staining. Its presence is due to faulty collection of the specimen.

Diagnosis.

Bladder irritation, nocturnal frequency, and the passage of hazy or purulent acid urine in a subject between the ages of 20 and 40 are strongly suggestive of tubercle.

The abdomen, lungs, lymphatic glands, and in the male the epididymes, prostate, and seminal vesicles, must be carefully examined. Tuberculous deposits in the genital tract are not necessarily primary infections; they may quite well be secondary to renal tuberculosis. Specimens of bladder urine must be examined both bacteriologically and microscopically by a competent pathologist. If tubercle bacilli are not found, even after repeated examinations, the diagnosis is still in doubt.

The next step should be a cystoscopic examination. Prior to this a dose of urea (for Maclean's urea concentration test) or an injection of indigo-carmine should be administered to enable the surgeon to ascertain the function of the kidneys. The appearance of the bladder and ureteric orifices is carefully noted. If the two orifices are similar in appearance both are catheterized and the urines collected. The renal function is estimated from a portion of these specimens, and the remainder is examined for tubercle bacilli, pus cells, etc. In doubtful cases guinea-pigs are also inoculated. If one ureteric orifice is obviously tuberculous the opposite one alone is catheterized; should its urine contain the slightest trace of pus a guinea-pig should be inoculated and the result awaited before the kidney can be declared healthy.

Treatment.

As surgical renal tuberculosis is primarily unilateral, and as spontaneous cure is unknown, the treatment can be summed up in two words—early nephrectomy. Before an operation is performed the function and condition of the opposite kidney must be carefully investigated. The diseased kidney and any adherent fat should be removed by the lumbar route. It should never be incised to verify a diagnosis which should have been certain before the operation, otherwise the surrounding tissues will be infected and the wound take months to heal.

In bilateral cases where the disease of one kidney is slight the grossly infected one should be removed, for nephrectomy relieves the bladder symptoms and may benefit the remaining kidney by increasing its congestion.

Nephrectomy is contraindicated (1) when the function of the opposite kidney is defective; (2) in advanced bilateral tuberculosis; (3) in slight bilateral tuberculosis; (4) when the disease is secondary to pulmonary or other gross tuberculous lesions.

Treatment of the Ureter.

When the ureter appears healthy it may be ligatured in two places, injected with pure phenol, and divided a few inches below the kidney. When it is thickened or much enlarged and dilated total ureterectomy is advisable, for high division may be followed by a tuberculous sinus or a urinary fistula. The operation I perform in these cases is nephro-ureterectomy through a lumbar and an inguinal incision, the ureter being divided at the base of the bladder and removed, still attached to the kidney, through the lumbar wound.

In most cases the wounds heal per primam, but occasionally in debilitated subjects, and particularly if the perinephric tissues are infected, there may not be the least attempt at healing, and after removal of the stitches the whole wound gapes widely open. This has happened to three of my cases, and in each the wound took more than a year to heal.

Results.

The operative mortality is about 2 per cent. Out of 100 cases which have survived the operation 60 will be cured and 40 will have persistent urinary trouble. Of these latter, 30 will die in from three to five years of tubercle of the opposite kidney or elsewhere in the body, and 10 will be left with either frequency alone or frequency and pyuria.

TUBERCULOSIS OF THE BLADDER.

Vesical tuberculosis probably never occurs as a primary lesion, but is always secondary either to renal tuberculosis, the infection reaching the bladder in the urine or from the walls of the ureter; to genital tuberculosis via the seminal vesicle and prostate; or, in rare instances, to tuberculous salpingitis by direct extension from an adherent Fallopian tube.

The infection tends to spread in a downward direction to the urethra and prostate and thence to the seminal vesicle and epididymis. When the walls of the bladder are ulcerated the infection may ascend to the kidney by the peri-ureteral lymphatics.

The tuberculous process, when secondary to renal disease, commences around the ureteric orifice, and on the base of the bladder when secondary to genital tuberculosis. Tubercles form in the submucous tissue, giving rise to raised hyperaemic patches in the mucous membrane, which tend to form superficial or deep ulcers, with a ragged shreddy base. As the ulcers deepen the muscular wall of the bladder is invaded, causing contraction and great diminution in the capacity of the viscus, and thus accounting for the distressing frequency and incontinence so typical of vesical lesions.

A diagnosis cannot always be made by examination of the urine, for in many cases tubercle bacilli cannot be found. In these cases tuberculous nodules in the genital tract or a thickened ureter, combined with the cystoscopic appearances, will solve the problem.

Treatment.

The immediate treatment is removal of the primary focus—either the kidney or the affected portion of the genital tract. When both renal and limited genital tuberculosis coexist the kidney and ureter must be removed first, and the genital tract operated on at a later date. Provided the patient is otherwise healthy the results of such radical treatment are often remarkably good. After removal of the primary focus the bladder will often recover without further treatment, but when the cystitis does not subside both general and local treatment are necessary.

General treatment consists of rest in bed, bladder sedatives, and tuberculin.

Local Treatment.—Instillation of many different chemicals has been advocated and employed, but they seldom have much effect, and their introduction into the bladder may lead to septic infection. In my experience surgical diathermy is the best form of local treatment, but if this cannot be obtained relief is sometimes given by instillation of either gomenol oil 20 per cent., or of iodoform (1 part) and guaiacol (5 parts) in sterile olive oil (100 parts). Diathermy is performed at intervals of three weeks with a catheterizing cystoscope, and the granulation tissue or ulcer is gently fulgurated. Fulguration relieves pain, diminishes frequency, and assists healing. Suprapubic cystostomy and drainage is not advisable, for it is difficult to perform on a contracted bladder, gives little relief, and is followed by tuberculous infection of the wound.

GENITAL TUBERCULOSIS.

Genital tuberculosis usually occurs between the ages of 20 and 45. The infection may be primarily haemic, when it can commence in any part of the genital tract; or it may be secondary to urinary tuberculosis, when it spreads by way of the prostate to the seminal vesicles and epididymes.

Clinical and experimental evidence shows that the primary focus is generally in the prostate or seminal vesicle, and statistics favour the seminal vesicle. Young of Baltimore, in a recent article, states that the seminal vesicle is affected in 83 per cent. of cases of genital tuberculosis, and that in a large majority of these the vesicle was the seat of the primary focus. The work of Macfarlane Walker and others points to the same conclusions.

With certain peculiarities the pathological changes are similar to those of tubercle elsewhere, and, as in the kidney, the foci may be closed or open. The prostate is generally more often infected from the urine or from the seminal vesicle than from the blood. Cold abscesses form and discharge into the urethra or rupture into the base of the bladder at the side of the trigone, leaving a ragged cavity which never heals. The lower end of the seminal vesicle is more often affected than the upper, but the whole tube may contain caseous foci and tuberculous "pus."

The character and sites of the tuberculous deposits in the epididymis and vas are of great interest, and point strongly to the infection of the epididymis being secondary to a primary lesion of the seminal vesicle or prostate. The earliest and also the oldest foci are found in the globus minor, whence extension takes place along the convoluted tubes to the globus major and finally to the body of the testis. Primary deposits in the globus major are comparatively uncommon, and are probably correctly regarded as haemic infections.

Thickening of the vas is most marked at its two extremities, the intermediate portion being often comparatively healthy. This intermediate portion often feels thickened, but the increase in size is due to surrounding inflammatory fibrosis and not to changes in its walls or lumen. In advanced cases deposits of caseous material are found throughout its length. Macfarlane Walker in his Hunterian Lecture (*Lancet*, February, 1913) showed that the thickening of the prostatic end of the vas was due to tuberculous infiltration of the perideferential lymphatics, which gradually diminished as the epididymis was approached, and that thickening of the testicular end was due to tuberculous deposits in its mucosa. He therefore considered that the clinical fact of the earliest lesions of the epididymis being in the globus minor was explained by extension of infection from a primary focus in the seminal vesicle or prostate by way of the perideferential lymphatics and a return in the lumen of the vas.

The conclusions arrived at by many clinicians that genital tuberculosis is secondary to a primary focus in the seminal vesicles are borne out by the results of simple castration, for 50 per cent. of such cases develop tuberculous epididymitis in the opposite side within a year or more.

The disease commences insidiously and progresses slowly. Though complete arrest is uncommon, there may be long periods of quiescence ending in increased activity and rapid extension. The prognosis is bad, owing to the frequency of relapses, the constant danger of extension to the bladder, and of dissemination to other parts of the body.

Treatment.

In advanced cases medical and general treatment is indicated, as surgery offers little prospect of cure, but when the disease is limited to the epididymis and seminal vesicle radical operation is indicated. It should consist of removal *en bloc* of the epididymis (or epididymis and testis), the vas deferens, the seminal vesicle, and when necessary a portion or the whole of the prostate. The operation can be accomplished through an inguinal incision by Loughnane's method, but if the prostate is involved Young's combined inguino-perineal method is necessary. Should the disease be secondary to unilateral renal tuberculosis the affected kidney must be removed first and the operation on the genital tract postponed to a later date.

In all cases tuberculin is of great value, but only after operation. In my experience it has not the least effect on well established urogenital tuberculosis, and should never take the place of surgery if removal of the disease is possible.

An Address
ON
THE CONSTITUTIONAL FACTOR IN DISEASE.

DELIVERED BEFORE THE ULSTER MEDICAL SOCIETY,
BY
ARTHUR F. HURST, M.A., M.D.OXON., F.R.C.P.,
PHYSICIAN TO GUY'S HOSPITAL.

(*Concluded from p. 827.*)

BLOOD PRESSURE AND CONSTITUTION.

DISCUSSIONS on abnormal blood pressure have in the past suffered from our ignorance as to what constitutes the normal. Stocks[21] has recently investigated the blood pressure of 1,323 English boys, and the extensive investigations of Alvarez[22] and his colleagues on 6,000 male and 8,934 female first-year students at the University of California have provided reliable figures for young adults. The statistics published by Symonds[23] of 141,840 applicants for insurance in an American company give additional data for all ages above 15, the smallest group (over 60) being no fewer than 1,889. In children there is a steady rise in systolic pressure from an average of 85 mm. at 5 to 101 mm. at 10 and 123 mm. at 15. Contrary to what might be expected, there is no rise with advancing years from 17 to 40, the average systolic pressure being 125 mm. in men and 115 mm. in women. After 40 there is a slow rise, the maximum average being 135 mm. for 60 and over, but there is no longer any difference between the sexes.

In healthy individuals of the same age, sex, and race considerable variations occur. Thus Alvarez and his associates found that among the students they examined 2.77 per cent. men and 11.74 per cent. women had a systolic blood pressure less than 105 mm., and 20.81 per cent. men and 3.75 per cent. women had a blood pressure over 140 mm. It is, of course, impossible to draw exact lines above and below which the blood pressure should be regarded as abnormal. For convenience I would suggest that hyperpiesia is present when the blood pressure is more than 25 mm. above the average normal for an individual's age and sex. This would give a limit of 150 mm. in men and 140 mm. in women up to the age of 40, and 160 mm. for both sexes at 60. According to this standard, 8.15 per cent. men and 3.75 per cent. women among the 15,000 healthy students examined by Alvarez had hyperpiesia.

No such sliding scale is required for hypopiesia. American writers generally take 110 mm. as the minimal normal figure, but Alvarez's investigations clearly show that this is too high. A preferable limit would be 105 mm. for men and 100 mm. for women. According to this definition it was present in 2.77 per cent. of the 6,000 men and 3.50 per cent. of the 8,934 women among Alvarez's first-year students.

There is no doubt that the tendency to hyperpiesia is hereditary. Long before the invention of the sphygmomanometer the familial occurrence of high blood pressure, apart from disease of the kidneys, was recognized, and it was well known that many members of successive generations of a family might die from such results of high pressure as cerebral haemorrhage and cardiac failure, associated with arterio-sclerosis and hypertrophy of the heart. The tendency to hypopiesia is probably inherited with equal frequency. The actual cause of the high or low blood pressure is quite unknown, though it is probably, at any rate in part, due to variations in the activity of such internally secreting organs as the suprarenal, the pituitary, and the thyroid glands.

I believe that hyperpiesia and hypopiesia should be regarded as constitutional conditions or diatheses, being simply extreme degrees of variation from the average normal. They are not diseases and need never give rise to symptoms, but an individual with either condition is apt to react in a special way to toxaemias and to mental and physical fatigue.

The diffuse hyperplastic sclerosis of the arteries, described by Evans as a constant pathological finding in hyperpiesia, is, I am convinced, a result, like the cardiac hypertrophy, of the constitutional high blood pressure, and not its cause. Clinically hyperpiesia may be associated with apparently perfectly healthy blood vessels, especially in young subjects before the pressure has become excessive.

(a) Hyperpiesia.

So much has been written on the subject of hyperpiesia since the classical analysis of the condition by Sir Clifford Allbutt that I have little to add. I think, however, that too much time has been expended in looking for some toxic cause, when in reality true hyperpiesia, as distinct from the high blood pressure secondary to chronic renal disease, is not a malady but a diathesis—a constitutional inherited condition. So far as I know, Dawson and Ryle[4] are the only recent writers who have laid much stress on this aspect of the subject. Ryle has pointed out that the stout, healthy looking, John Bull type of individual is generally the subject of hyperpiesia, which is not acquired but is inborn. Among his patients with hyperpiesia 62 per cent. were of this type, 18 per cent. of average build, 4 per cent. "lean and nervous," and 16 per cent. of poor physique. The question might arise whether the exceptions were really suffering from primary hyperpiesia; in the lean and nervous individual I believe that a high blood pressure is generally secondary to the mental state. I found during the war, in cases of functional hyperthyroidism associated with a high blood pressure, that simple hypnosis often resulted in an immediate fall, amounting even to 45 mm., when the state of anxiety in which the patient lived was temporarily removed. A boy of 16, recently under my care, had an acute attack of nephritis from which he recovered completely, except that the blood pressure remained constantly in the neighbourhood of 156 mm.; as his urine was normal, the blood urea not raised, and the urea concentration test gave a normal result when he came under my observation six weeks after the onset, I allowed him to get up, and told him that his prolonged stay in bed had at last cured him. The next day his blood pressure had fallen to 120 mm., and it remained at this normal level, the previous rise having apparently been due to continuous anxiety, although he always appeared cheerful enough, but bored at having to stay in bed.

The typical hyperpietic has certainly a hypersthenic habitus; he is well built, with broad shoulders and a short, deep thorax with wide costal angle; he has a ruddy complexion, and may be actually plethoric; he is often athletic, unless overindulgence in food and drink has led to a crippling degree of obesity.

Hyperpiesia is often an accidental discovery in an apparently healthy man of exceptional mental and physical vigour. But sooner or later symptoms appear, generally as a result of mental or physical overwork, prolonged worry, excess of food and drink and perhaps of tobacco, or an acute or chronic infection. In women symptoms may develop at the menopause.

The symptoms are generally not due to the high blood pressure itself, but to its effects on the blood vessels or heart. Thus arterio-sclerosis impairs the blood supply to various organs, such as the brain and kidneys, which become

functionally inefficient, though in the case of the latter the blood urea never rises to the extent it does in primary renal disease; the loss of elasticity of the arteries may render them incapable of withstanding the strain of the high blood pressure, so that retinal and cerebral haemorrhages and epistaxis may occur. In spite of its hypertrophy the heart may eventually be defeated in its attempt to maintain an adequate circulation against the great peripheral resistance; cardiac symptoms, such as dyspnoea and precordial pain, then develop. The only symptoms which may perhaps be directly due to the high blood pressure are headache and vertigo, though even these are often absent in people with a blood pressure exceeding 200 mm.

When symptoms once appear in people with hyperpiesia the prognosis is never good, as there is an ever-present danger of death from cerebral haemorrhage or cardiac defeat, though this may of course not occur for several years.

(b) *Hypopiesia.*

Although hypopiesia—an abnormally low blood pressure occurring independently of any organic disease—is as common as hyperpiesia, much less attention has been paid to it. It may be defined as a constitutional and often inherited condition, in which the systolic blood pressure is permanently below 105 mm. in men and below 100 mm. in women, without recognizable cause, such as tuberculosis, circulatory failure, severe anaemia, hypothyroidism, or Addison's disease. It is often discovered accidentally in perfectly healthy individuals. Further investigation generally shows that they are of hyposthenic habitus—thin, slouching, with long and narrow chests and acute epigastric angle. They are rarely athletic, and they generally choose a sedentary occupation.

Though not actually ill, the hypopietic is rarely very well. His most common symptoms are undue liability to mental and physical fatigue and a general lack of endurance, which is often in striking contrast with the heroic efforts he makes to carry on in spite of his disability. He is often subject to headaches, especially in the occipital region, and to attacks of vertigo, and more rarely of palpitation and syncope. He is generally pale, though not anaemic, and suffers from cold extremities. These symptoms are most likely to arise as a result of mental and physical strain or some acute or chronic infection or toxaemia, which would either have had no effect or only a slight and temporary one in individuals with an average blood pressure.

Fisher[24] found that the mortality of 3,589 persons, aged between 16 and 60, accepted for insurance, who had a systolic blood pressure of 100 mm. or less, was 35 per cent. of the expected mortality according to the standard American tables, whereas the general mortality among those insured by the company was 80 per cent. of the expected rate. According to Muhlberg,[24] the medical director of another insurance company, a low blood pressure after the age of 50 without any obvious cause is the best criterion we possess that an individual will live beyond his normal expectancy.

Treatment of Hyperpiesia and Hypopiesia.

People with hyperpiesia and hypopiesia should be made to understand that they are not suffering from a disease, but that a constitutional tendency has been discovered in them, which indicates the desirability of care in certain directions in order that the maximum of physical and mental efficiency may be attained and preserved. It would probably be wise, when possible, to avoid all reference to blood pressure, and it is certainly most undesirable that the patient should keep a record of its variations. The last few years have introduced a new type of hypochondriac, and blood pressure has become one of the favourite topics of discussion at tea-tables and in club smoking-rooms. I once spent an unhappy week at a large hotel in one of the British spas where hyperpiesia is treated; my fellow guests appeared to have no other interest than in comparing the variations in their respective blood pressures. I have often been consulted by patients, who looked and felt perfectly well, for "blood pressure," which they apparently thought was the synonym of a serious disease.

It is even more essential for the subjects of hyperpiesia and hypopiesia than for the average man to take adequate holidays. But whereas the hyperpietic should be taught to restrict his exercise within more moderate bounds than those to which he has probably been accustomed, the hypopietic should be urged to take as much exercise in the open air as he can without exhaustion, even if, as is often the case, he has in the past taken little or none. He will often find that a holiday in the Swiss mountains will make him more physically efficient than he had thought was possible, and he may become an expert in such sports as climbing in the summer and ski-ing in the winter, which are quite unsuitable for the hyperpietic. Whereas the hyperpietic should be strictly moderate in his consumption of tobacco, alcohol, and coffee, and should even give them up entirely if previously taken in excess, such restrictions are rarely called for with the hypopietic; a cup of black coffee and a pipe after dinner and an occasional half-bottle of champagne will materially help him to enjoy work which would otherwise require an almost intolerable effort. Restriction in the quantity of food, which should be as largely vegetarian as possible, for the stout and plethoric hyperpietic is essential, whereas the thin hypopietic should be urged to eat plentifully without restrictions as to the consumption of meat. For both types any source of infection should be looked for and treated. I have seen several hyperpietic patients, who had more than the normal percentage of haemoglobin, benefit greatly from periodic bleeding, though it did not appear to lower their blood pressure; when well marked plethora is present the application of deep x rays to the long bones may throw out of action sufficient red marrow to reduce the number of blood corpuscles to normal limits, and at the same time cause a definite fall in blood pressure. In addition to outdoor exercise, physical drill, especially directed to the respiratory and abdominal muscles, is very useful for the hypopietic, who may also derive much comfort from the use of an abdominal support.

The Constitutional Factor in Asthma, Epilepsy, and Migraine.

Several years ago[25] I defined asthma as a condition in which that part of the vagal nucleus which controls the motor and secretory activity of the bronchi is abnormally sensitive to chemical, reflex, and psychical stimuli. The importance of this definition lies in the recognition of the sensitive bronchial centre. In the first decade of the present century many rhinologists were so impressed with the results of the nasal treatment of asthma that they were inclined to regard an abnormal nose as the sole etiological factor. More recently the work of a number of investigators in England and America and on the Continent has directed attention to the importance of specific hypersensibility to the proteins of bacteria, food, animal emanations, and pollens, and most of the recent literature of asthma would lead one to suppose that in this—the "toxic idiopathy" of Freeman—is to be found the whole explanation of asthma. Lastly, a few enthusiastic neurologists would regard asthma as always of psychological origin. Attacks of asthma may, in fact, be caused by a great variety of reflex and chemical stimuli, as well as occasionally by psychological stimuli, but only if the individual has the asthmatic constitution, which manifests itself in an irritable bronchial centre, this being the one essential factor in the pathogenesis of asthma. It was inherited in 49 per cent. of 1,129 cases collected from various sources, compared with only 7 per cent. of 115 controls, and it is interesting to note that an individual may inherit it and transmit it to his children, without ever having an attack of asthma himself owing to the absence of the three groups of exciting causes. Thus the paternal grandparent and uncle and maternal grandmother and aunt, but neither parent, of one of my asthmatic patients suffered from asthma.

The question of inheritance of asthma is complicated by the fact that a toxic idiopathy, though sometimes acquired, may also be inherited, either in the form of a general hypersensitiveness to proteins, or, much less frequently, in a specific form to a single protein. Asthma does not, however, necessarily occur in each individual

with a toxic idiopathy, as the asthmatic constitution may not be present. A toxic idiopathy will give rise to asthma, hay fever, urticaria, or angio-neurotic oedema, vomiting or diarrhoea, or vasomotor neuroses of various kinds, according to whether the individual affected has a bronchial centre, nose, skin, alimentary tract, or vasomotor centre which is abnormally irritable. Two of the conditions may be present together, or they may occur in different members of the same family; thus asthma is frequently associated with hay fever and sometimes with urticaria, and a family history of hay fever is common among asthmatics, and vice versa. Just as an inherited asthmatic centre may be present in an individual who never gets asthma, though he may transmit it to his children, so a toxic idiopathy may be transmitted by an individual who is otherwise so normal that he never suffers from its effects. As toxic idiopathies give rise more frequently to asthma than to any other condition, it seems probable that the asthmatic constitution is one which is particularly likely to develop such idiopathies.

The clinical picture presented by the other most important paroxysmal neuroses—epilepsy and migraine—resembles asthma so closely in certain respects that the question of their relation with each other requires consideration. Epilepsy depends upon the presence of a constitutional and often inherited excitability of some part of the nervous system, which responds to certain stimuli by the production of an epileptic attack. The nature of these stimuli is, however, quite unknown in the majority of cases; the most important is perhaps chemical in nature, but there is no evidence to support the theories that intestinal intoxication or toxic idiopathies play any part. Reflex and psychical stimuli also occasionally give rise to attacks, but they are of comparatively small importance. A family history of epilepsy in an asthmatic or of asthma in an epileptic is so uncommon that, when it occurs, it cannot be regarded as more than a coincidence, and I have only seen one case in which asthma and epilepsy occurred in the same individual.

Migraine also depends upon a constitutional and frequently inherited irritable focus in the brain, which gives rise to headache, disturbances in vision, and gastric symptoms; there was a family history of migraine in 30 out of Bramwell's[26] 54 cases (55.6 per cent.). In migraine the usual stimulus is ocular, and a very thorough investigation in numerous cases under my care has invariably failed to reveal anything in the nature of alimentary toxaemia, hepatic insufficiency or a toxic idiopathy, which could be held responsible, in spite of the fact that on theoretical grounds these have frequently been suggested as the exciting cause of attacks. The evidence of a psychological origin is also quite insufficient except in rare cases, in which, however, eye-strain also invariably plays a part. I have only met with one case in which migraine and asthma were associated in the same individual, and there is no evidence that they occur together in the same family more than would be expected from the frequent incidence of both conditions among the general population. The same is true with regard to the association of migraine and epilepsy, so that it may be concluded that the constitutional basis of asthma, epilepsy, and migraine, though somewhat similar in nature, is in each case specific, and that no one of these conditions in a parent predisposes to the development of either of the other two in the children.

Long ago, in discussing the treatment of the constitutional basis of asthma, I said that the only cure of asthma is not to have it. The same is true of epilepsy and migraine. The longer a patient can be kept free from attacks by any form of treatment, the less irritable his abnormal nerve centre becomes, though it is doubtful whether the constitutional hypersensitiveness is ever entirely lost in asthma or epilepsy, though with advancing years the complete cessation of migraine attacks is not uncommon. A patient of mine, who had been free from asthma during a residence of twenty-five years in South Africa, developed an exceedingly severe attack on his return to his home in England, where as a boy he had been almost constantly asthmatic. I have known many epileptics relapse directly they gave up taking bromide, which they had been told they could discontinue after they had been free from attacks for one, two, or three years. It is true that the liability to attacks steadily diminishes as the period of freedom lengthens, but I am inclined to think that nobody who has once suffered from epilepsy should ever discontinue the use of small doses of bromide or luminal, even if he remains free from fits for five or ten years. Kinnier Wilson has recorded the case of a lady who had only two attacks in her life, the interval between them being no less than thirty years.

Conversely, the more attacks an individual with asthma, epilepsy, or migraine has, the more irritable his centre becomes. An asthmatic develops the status asthmaticus, in which the treatment he usually employs for an attack fails to help; nothing will then relieve him until he has moved to some more favourable surroundings, where rapid recovery will generally take place.

The *faiblesse irritable* of the nervous system, which is the ordinary sequel of mental and physical fatigue, increases the constitutional irritability of the nervous centre upon which the paroxysmal neurosis depends. Consequently it is of the utmost importance for individuals who are subject to asthma, migraine, or epilepsy that the work of each day should be limited in duration, that the week-end should be sufficiently restful, and that two annual holidays of adequate duration should be taken. This is particularly important in the case of asthma and migraine, both of which tend to occur in people whose mental capacity often leads them to adopt a career in which overwork is likely to occur.

Unfortunately there is no drug which exerts a favourable influence on the constitutional factor in asthma comparable with that of luminal in epilepsy and migraine and of bromide in epilepsy. Climate has, however, a remarkable effect, quite apart from the influence of vegetable and animal emanations which may render one place unsuitable to some asthmatics without having any effect on others. Thus asthma hardly ever occurs among the permanent residents of the Swiss mountains, and many asthmatics who, in spite of the greatest care with regard to diet, the avoidance of fatigue, and other exciting causes, have asthma more or less continually whilst at home and are unable to take any active exercise or even walk upstairs without dyspnoea, become entirely free within a day or two of their arrival in the mountains, where they can climb all day in summer and ski or skate in winter without respiratory distress. That the climate exerts a specific influence in diminishing the irritability of the bronchial centre is shown by the fact that chemical and reflex stimuli, which would cause violent attacks at home, no longer produce the slightest ill effect. This is perhaps one of the strongest arguments against those who regard nasal abnormalities or toxic idiopathies as the only factor worthy of consideration in the pathogenesis of asthma and entirely neglect the essential constitutional element in the disorder.

No child should be allowed to go to school or spend his holidays in a place where he is asthmatic. I knew an Eton boy whose home was in London and who was always in the status asthmaticus whilst at school; this could be interrupted by sending him to Paddington Station for a few hours, but returned as soon as he got back to Eton. If he had stayed at Eton the constitutional basis of the disorder would have been so firmly established that the prospects for the rest of his life would have been seriously affected. He was removed on my advice, and is now at a school where he has no asthma.

In the comparatively rare cases in which it is impossible to find a place in England where a child is free from asthma, and where rhinological, immunological, and other treatment has failed to give relief, a year's residence in the Swiss mountains is likely to save him from becoming a permanent invalid. The removal of chemical and reflex causes is likely to be futile if the constitutional element of the disease is neglected; such treatment is always most effective if carried out during a period of comparative or complete absence of symptoms.

"GASTRIC ATTACKS" IN CHILDHOOD.*

BY

DONALD PATERSON, M.B., M.R.C.P.,

PHYSICIAN FOR THE DISEASES OF CHILDREN, WESTMINSTER HOSPITAL; PHYSICIAN TO OUT-PATIENTS, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

THE usual age at which gastric attacks occur in childhood is between 2 and 7 years, probably most commonly between 5 and 6. By "gastric attacks" I mean a train of symptoms which points to the alimentary tract as the seat of the disturbance. Thus a child aged 3 refuses his tea, seems fretful, out of sorts, a little feverish, and alarms the household by vomiting, during the evening, some of the food taken at his dinner. The doctor is summoned in the morning, finds his patient with a temperature and a dirty tongue, drowsy, irritable, and still refusing food. In the course of the next few days recovery takes place. The picture varies enormously, depending on the underlying cause and on the particular child. Thus the child may show a very slight disturbance and be nauseated only. Again, the vomiting may be profuse, the bowels may be obstinately constipated with pale motions, or there may be profuse diarrhoea.

The common causes of gastric attacks are, in my opinion, (*a*) infections in the alimentary tract or elsewhere; (*b*) dietetic errors; (*c*) overexertion and excitement. There seems no doubt that the first is far and away the commonest.

Infections.

The so-called cyclical vomiting attacks (to be discussed later), where the condition recurs over and over again at more or less regular intervals, may be closely simulated by recurrent tonsillar infections. Thus a small child with acute tonsillitis may make no complaint, but refuse its food, become feverish, drowsy, irritable, and through the presence of acetone bodies, formed as a result of the infection, complain of nausea, or vomit. The tonsillar infection may, directly or indirectly, affect the liver, so that the old term "chill on the liver" would aptly describe the situation. On the other hand, the stomach or bowel may be infected, secondarily to this tonsillitis. Careful inspection of the throat should always be made in every "gastric" case. The removal of tonsils should be advocated if such cases should show a tendency to recur.

In thin, nervous, dyspeptic children, especially little boys, and particularly only children or the youngest in the family, catarrhal infections of the nasopharynx or chest may precipitate the condition described, so that the gastric symptoms completely dominate the picture. In girls chronic pyelitis should always be thought of. In these cases, a number of which I have recently been studying, bouts of mild fever occur at more or less regular intervals of two, three, or four weeks. Examination of the urine between attacks may show surprisingly little pus, but during the febrile attack much pus appears. A catheter specimen, both during and between attacks, shows the presence of the infecting organism on culture (as a rule *Bacillus coli*). But the indications for obtaining such a specimen between attacks are not definite, and the result is that cases are missed. During the attack the presence of pus is masked by urates and phosphates, and it is only by the microscope that the real condition of affairs can be ascertained. The bouts of fever are accompanied by drowsiness, lassitude, anorexia, and, if food be pressed, by nausea and vomiting. The result is that they become known in the family as "gastric attacks."

During the influenzal season gastric attacks are common and receive the name "gastric flu." In such cases the onset is extremely sudden, the vomiting is often accompanied by diarrhoea, and there is little doubt that the mucous membrane of the alimentary tract is the direct site of the infection.

Dietetic Errors.

At this age slight variations in diet will not produce gross symptoms in the average child. We should not therefore commence an examination of such a patient with the thought in our mind that he has only probably overeaten. It is true that such may be the case, but I believe only in a minority of cases; infections are the predominating cause. There is a type of child who appears to have an inherited inborn tendency to "liverishness." His mother or father was liverish as a child, and may exhibit train or tram sickness or headaches in adult life. Their child is termed the "nervous child," and most often he is found to be their only offspring. This little fellow—for as a rule it is a boy—gets recurrent gastric attacks at more or less regular intervals throughout the year, becoming less and less frequent as he approaches the school age. A consideration of his diet shows that he tends to be overfed on milk, cream, and eggs, and the overanxious mother, seeing his frail little body, plies him with what she considers the most nourishing food. The treatment of such a case is obviously the reduction of fats. Cream must be abolished, eggs and milk reduced to a minimum, certainly not more than two eggs in the week or half a pint of skimmed milk in the day. To metabolize what little fat he gets a maximum of carbohydrate must be given, and this can best be done by offering barley-sugar, jam, golden syrup, treacle, or honey at the end of the mid-day and evening meals. A régime must be adopted whereby three meals only are given and nothing allowed between them. Instead of the child losing weight on this apparently scanty diet he will, paradoxical as it may seem, rapidly put on weight.

In my opinion the error of overfeeding on fat as above described is by far the commonest dietetic error made.

The clinical picture of the above case may show some of the following features. For twenty-four hours the child appears to take his food extraordinarily well. The following day he is irritable, drowsy, and yawning with anorexia, and this is followed by a sudden onset of violent vomiting, when even sips of water are returned. Cramps and colicky pains about the navel occur next, and the parents fear the onset of appendicitis. The abdomen, however, is not tender, and is inclined to be flat. The bowels, as a rule, are constipated, and the urine is filled with acetone and diacetic acid. The management of the attack should commence by getting the bowels to move. Small doses of calomel (1/6 or 1/4 grain) should be given with 5 to 10 grains of sodium bicarbonate hourly until the bowels move. Glucose water and sweetened drinks of fruit juice should be given in sips. As a rule, with the opening of the bowels the vomiting ceases, and drinks of water should then be pushed, when recovery will be rapid. Single isolated bilious attacks due to gross indiscretions of diet are likely to occur in any normal healthy child, and may simulate this picture; the treatment is identical.

Overexertion and Excitement.

In examining the child with a gastric attack we should ascertain whether previous attacks have occurred, and having excluded infection and gross dietetic errors the possibility of overexertion being the cause should be considered. It would appear that a certain proportion of the available blood sugar is required for fat metabolism. With great mental and physical exertion—so that the child becomes overtired—the available supply of sugar is deficient for fat metabolism and the general body nutrition. An attack of vomiting or nausea occurs, very similar to those attacks of hypoglycaemia seen in the diabetic subject who has been given an overdose of insulin. In one such child, observed by Graham Ross in America, an attack could be precipitated at will by such means. Most adults can recall the faintings, giddiness, or nausea felt by them as children on some occasion when they went to school without breakfast. This, if slightly exaggerated, may easily develop into a so-called gastric attack.

I have not touched on the rarer causes of gastric attacks, such as food poisoning, nor have I mentioned those children who show violent vomiting and profuse diarrhoea at the onset of acute infections, such as scarlet fever, measles, or pneumonia; nor have I mentioned typhoid fever or dysentery, which ought always to be borne in mind. Comparatively speaking, these cases are uncommon, and those I have mentioned should [illegible] out of first.

* A lecture given to the Chelsea Division of the British Medical Association.

Diet.

A diet suitable for a boy of 5 or 6 who tends to have liverish or gastric attacks at intervals should be along these lines. On waking he should have a glass of orange, grapefruit, or grape juice, sweetened with four lumps of sugar. Breakfast, half an hour to an hour later, should consist of some cereal, such as porridge, groats, cream of wheat, puffed rice, or shredded wheat, with a very little milk but well sweetened with sugar. As a second course, on two days in the week he may have an egg, and on four days, crisply done, very thin rashers of bacon, which should be fried until the fat has been mainly removed and allowed to drip, so that a minimum of grease or fat remains. Fish should be given on one or two mornings. Crisp toast and butter with freshly brewed tea or Horlick's malted milk, or well skimmed milk and water, equal parts, one cupful only, complete the meal. Nothing should be given all the morning. For dinner—and it is best to have early dinner with these children, say at 12.30—fresh mince or stew, underdone beef or steak or cutlet, should be given on four days in the week, with chicken or fish or brains on three days. A small portion is sufficient. Potato and green vegetables, a tablespoonful of each, should also be given. Milk pudding or stewed fruit, but not suet pudding, should follow, and the child should have water to drink. At tea —*4.30 to 5 p.m.—thin bread-and-butter or crisp toast, with* stewed fruit, jam, treacle, honey, golden syrup, or a little milk pudding, may be given. The drinks should be the same as at breakfast. In winter a bowl of soup may be taken at this meal.

The child should not have an excess of eggs or cream, much creamy milk, pastry, or suet pudding, chocolate, or cocoa.

GENERAL MEDICAL PRACTICE AND THE MEDICAL CURRICULUM.*

BY

J. M. MUNRO KERR, M.D.,

REGIUS PROFESSOR OF MIDWIFERY IN GLASGOW UNIVERSITY.

You can readily understand that my return to this class-room as Regius Professor awakens many memories—memories of undergraduate days of almost unalloyed happiness, and later memories of early essays as a teacher during the years when I was assistant to Professor Murdoch Cameron, who had succeeded to the chair in 1894. The decade immediately preceding this year was most eventful, not only in surgery but also in obstetrics and gynaecology. It witnessed the birth of surgical obstetrics and gynaecology. Quick to recognize this development, more especially as it affected obstetrics, Professor Cameron introduced into the Glasgow Maternity Hospital the modern operation of Caesarean section which Sänger of Leipzig had evolved in the early eighties. The successes he secured and reported focused the eyes of the obstetric world on the school of Glasgow. I feel sure you desire to be associated with me in wishing Professor Murdoch Cameron many years of enjoyable leisure.

In selecting a subject for the inaugural address which use and wont prescribe, my chief difficulty was in deciding whether to review the past or forecast the future. I have chosen the latter, for to forecast the future is one of the few adventures left to the middle-aged. Besides, there is a certain fitness in the choice, because to you the future is everything. It occurred to me, therefore, that as most of you will ultimately embrace the arduous but very honourable calling of general practice it might be of interest if I placed before you the future of general practice as I see it, and the manner in which the medical curriculum might be modified to suit the changing conditions which are slowly but steadily occurring in general medical practice.

We have reached a very important stage in the evolution of medical education. For many years the general trend of medical education has been along certain simple lines—namely, as knowledge in a department has advanced the policy followed has been increased instruction in the subject or subjects of that department, with the result that the student of the present day finds it impossible to digest the mental food provided. As a remedy it has been suggested to lengthen the curriculum; and when we consider the length of the medical curriculum in other countries as compared with ours—take Sweden as an extreme example with its eight to nine years—this policy might appear justifiable. But before adopting such a policy—which to those responsible for medical education is the easiest way out of the difficulty but to the student a most serious one—it will be advisable to consider whether some rearrangement or modification of the curriculum is possible.

It is conceivable that with the altered conditions as regards medical practice modifications in the curriculum might in great part get over the difficulty. This implies a correct forecast of the trend of general medical practice. Until this is determined it is impossible to decide how the curriculum should be altered to suit the requirements of the young graduate of to-day who is ultimately going to practise his profession as a general practitioner.

The future of general medical practice lies more and more in the direction of pure medicine, and the general practitioner must be raised in pure medicine to a very high level. He, associated more intimately with the consulting physician, clinical pathologist, and officer of health, is the individual whose assistance will be of inestimable value in advancing medicine. For, as the late Sir James Mackenzie pointed out repeatedly, on the general practitioner must we depend for the early recognition of disease —the field of medicine which at the present moment offers the most promising harvest. Though this will ultimately be the vocation for the general practitioner, it does not mean that he will occupy a less important place in the community, nor that he will be less beloved than the old-time family doctor. The general practitioner as I see him will occupy a more important place, and incidentally he will have an infinitely more interesting professional life. He will be brought into closer relationship with the consulting physician, the clinical pathologist, and the medical officer of health, who also will benefit, for hospital, laboratory, and office work has a tendency to produce a mentality too academic and bureaucratic.

Looked at from yet another standpoint, this co-operation between these different departments is becoming necessary to the teacher of clinical medicine and his students, for, as you are well aware, a number of diseases have been relegated to special hospitals which the medical student only occasionally visits, and in which, therefore, he has few opportunities for clinical study.

Some months ago, in the pages of the BRITISH MEDICAL JOURNAL, I had the temerity to refer to this question of the trend of general practice. Let me quote a few lines from the editorial[1] on the subject:

"General medical practice is not, as a fact, developing on lines such as those which Professor Kerr indicates as, in his opinion, desirable. So far from restricting himself to pure medicine, afraid to use a knife or any other surgical instrument, shrinking from responsibility for a maternity case in any of its stages, ante-natal, natal, or post-natal, the general practitioner, in partnership or association with his fellows, is finding it useful to his patients and advantageous to himself to undertake an even wider range of service than was at one time customary; and the results justify the method."

I am quite prepared to admit that individual practitioners and firms of practitioners find this policy advantageous to themselves. But general surgery and the surgical specialties, including obstetrics, are crafts, and craftsmanship only reaches its highest level when individuals in addition to having a natural aptitude for craftsmanship have continuous practice in their craft. This is not possible in general practice, no matter how large the practice may be. Further, the development of general practice on the lines above indicated introduces an

* Inaugural address (abbreviated) delivered on January 10th, 1927, on appointment to the Regius Chair of Midwifery in Glasgow University.

atmosphere of commercialism into medicine which we must ever strive to avoid if our profession is to retain the respect and confidence of the public. Fortunately, it is doomed to ultimate failure, for the wealthier community will continue to employ specialists; while those of moderate means and the artisan class will also insist on the services of specialists. Interesting in this connexion is the following sentence from the Hippocratic oath: "I will not cut for stone, even for patients in whom the disease is manifest; I will leave this operation to be performed by practitioners (specialists in this art)."

It is obvious that sooner or later some arrangement must be made to supply insured persons with advice and treatment in the various special departments of medicine and surgery. As a matter of fact, this has been done in dentistry and ophthalmology. Many of us remember the introduction of the National Health Insurance Act and the opposition it aroused. I have no hesitation in stating that this opposition and the behaviour of a certain number of the profession did great harm to the status of the profession in the eyes of the general public. Would these critics wish to see the Act repealed? There is no necessity for a similar controversy when the question of special treatment to insured persons is under consideration.

Having attempted to indicate the trend of general medical practice, let me now consider the medical curriculum. It is obvious that I cannot discuss this matter of the curriculum in detail. It is giving many of us much thought. Its importance is fully recognized by the General Medical Council, as evidenced by the fact that quite recently it asked for supplementary information and suggestions to the reports formulated by the different subcommittees of 1922.

The General Medical Council, if one reads the discussions and reports on the curriculum published, is far in advance of the times. It sees that radical alterations in the curriculum are necessary. But the conservatism of teachers generally, the vested interests of certain teaching bodies, and the jealousy of individuals regarding their particular subject are barriers to innovations which are very difficult to overcome.

Leaving aside for the present the purely scientific subjects and confining myself to the later clinical subjects, and more especially to obstetrics and gynaecology, let me indicate the training which I think suitable. In obstetrics the student should be trained to have a general conception of obstetric and gynaecological problems, and to be able to deal with ordinary deliveries. If he wishes to do more, he must have special post-graduate instruction and practical experience. The duration of this training need not be longer than three months, provided he gives up his whole time to the subjects of obstetrics and gynaecology. This was the recommendation of the Scottish subcommittee which dealt with this part of the curriculum in 1922.† And it is greatly to the credit of the Edinburgh school that it immediately adopted the recommendation. Another school which has adopted the principle as regards obstetrics and gynaecology is St. Thomas's Hospital. There Dr. Fairbairn, who directs the department, has followed the recommendation of the English subcommittee and established a six months' course, which includes not only obstetrics and gynaecology but also pediatrics. The reason for this longer course in St. Thomas's is that it, in common with many of the other London hospitals, has difficulty in providing sufficient clinical material for the teaching of obstetrics. Many American schools have arrangements somewhat similar, and in Sweden, which I visited last summer, a four months' course of concentrated teaching has been the arrangement for many years. Owing to the exigencies of obstetric practice it is only by such an arrangement that the student can be satisfactorily trained in obstetrics. Fortunately, in our school here in Glasgow we have abundant material and a large and well-appointed hospital. What is necessary is that the clinical teaching should be better organized and that systematic lectures should be cut down by at least half.

This brings me back to the extent or type of the training in obstetrics and gynaecology, and it is interesting to consider what other countries are aiming at. There may be said to be two opposing camps—one which aims at an extended training and a very thorough experience in obstetrics, so that the young graduate may be able to undertake almost any operation in obstetrics; this is especially advocated in some of the schools of America. The other school views matters quite differently. Its policy is to train the undergraduate only to a moderate extent. This type of training pertains to such countries as France, Sweden, and Denmark. These countries are aiming at an obstetric practice carried on by particularly educated and well trained midwives, assisted in cases of difficulty and supervised by specialists or specially trained accoucheurs distributed over the country—in other words, the establishing of an obstetric service very much on the lines I suggested in the paper already quoted. My reason for supporting this latter arrangement is because it is impossible for the general practitioner to obtain continuous practice in obstetric operations. If we take Glasgow as an example, we find that some 60 per cent. of confinements are attended by midwives.‡ Further, there is an ever-increasing number of women who elect to go into hospital for their confinements. Thus the experience that practitioners of former generations gained in their private practice is not available to the practitioners of to-day.

The great fault of the present system is that the student is not "steeped" sufficiently in clinical work; and, let me remark, this clinical experience and training should be as thorough in the outdoor department as in the wards, because so many minor ailments and early phases of disease are only seen in the outdoor department. As a matter of fact, the old system of apprenticeship whereby the young candidate of medicine was associated with a practitioner and gained his clinical experience from actual practice was most useful, and nothing in the clinical training since that system was abolished has quite taken its place. We must get back in a different form to the idea of apprenticeship.

I have indicated the training in obstetrics and gynaecology—namely, a whole-time concentrated course of three months as a minimum. As regards medicine and surgery, I speak with less assurance. I am inclined to the opinion, however, that clinical training in medicine should be increased and that possibly clinical training in surgery might be lessened. The clinical training of the undergraduate in medicine is not sufficient for present-day requirements. Further, ophthalmology certainly, and possibly some of the other medical specialties, should be given greater consideration.

Surgery is on a very different footing. No one to-day attempts to practise surgery seriously without some special post-graduate training. The great surgical principles, the possibilities of surgery, surgical pathology—these are the subjects to which the medical undergraduate's attention should be directed. The craft of surgery can only be learnt after graduation. I venture to suggest to my surgical colleagues that the training of the undergraduate in surgery might with advantage be modified to suit the requirements of general practice of to-day. The same applies to the surgical specialties.

Each of us engaged in the training of medical undergraduates must seriously consider medical education, not solely as it affects his own particular department, but with a broad outlook on the position of present-day medical practice. We must not attempt, as some countries are doing, to train experts in medicine, surgery, and the specialties. With the foundation well laid in biology, chemistry, anatomy (modified), physiology, and pathology, exactness in clinical observation is the first essential, and this I maintain can be developed to the fullest extent in medical wards. Again, I maintain that medicine, with the medical specialties, is the ultimate calling of the general practitioner.

REFERENCE.

† A subcommittee appointed by the Faculty of Medicine is at present considering the co-ordination of clinical teaching in the final year.

‡ Some districts of Scotland show 80 to 90 per cent. of confinements attended by midwives.

THE PART PLAYED BY INJURY AND REPAIR IN THE DEVELOPMENT OF CANCER;

WITH REMARKS ON THE GROWTH OF EXPERIMENTAL CANCERS.*

BY

PROFESSOR H. T. DEELMAN,

GRONINGEN.

CAN we demonstrate experimentally the reason for the very localized starting-point of a tumour, although a great number of epithelial cells had been in contact during days and weeks with the cancer-producing agent (tar in the case of the experimental tar cancer)?

Mice were tarred in the usual manner till some of the animals showed early papillomata. Under the microscope these tumours proved to be very localized epithelial hypertrophies. We know that in this stage of the experiment the skin of the mouse tends to form numerous tumours in a very short time when tarring is continued, but that if tarring is stopped at this stage only a very small number of tumours will appear. The tarring was stopped at this stage of the experiment and a few days afterwards incisions were made in the skin, care being taken to make them in places where no papillomata had appeared. These wounds very soon assumed an oval shape and healed in the normal time. There was first a layer of fibrin and dead cells, and under this material we very soon found the first symptoms of healing in the form of new epithelial cells. In the majority of cases we observed in the wounds —healed or partly so—new tumour processes. In some instances there were only two or three tumours in one scar, in others there were many more. I never observed that the whole scar was involved in the tumour process. Sometimes the tumour growths were so numerous that the scar could be localized with the greatest ease. I have said that the tumours appeared in some cases after the scar had healed and the new epithelial cells—that is to say cells never themselves in contact with the tar—produced in these experiments primary growths. We know there is a relation between tar and tumour formation; we now learn from these experiments that the liability to tumour formation can be transferred to daughter and granddaughter cells without the cells showing any change microscopically, nor in the biological sense. These tumours which we produced just at the place where we expected to see them were very malignant, and sometimes in a very short time the whole scar and the surrounding tissue were replaced by a typical cancer growth. We have thus an opportunity of getting a clearer insight into the local origin of tumours in a skin area where all the cells had been in contact with the cancer-producing material. Every now and then the animals get little wounds. These wounds may be so small that they escape attention. They heal as a rule very quickly, and we may suppose that some of them will produce a tumour in the same way as was shown in our experiments. In a very short time these tumours may be larger than the little (often almost invisible) scars from which they started. These experiments may have a general significance for the local beginning of a tumour.

Some other experiments throw a light on the old question of the manner of extension of a tumour. When we study the first beginning of a tumour we find a local hypertrophic growth. Somewhat later the surrounding cells hypertrophy also, and so on, until there exists on the skin a hypertrophic proliferation generally in the form of a papilloma. The way in which such a papilloma grows seems to indicate an influence of the central parts of the papilloma on the surrounding cells of the living organism, with the result that the latter also hypertrophy. At a later stage the central parts of the papilloma are changed into cancer cells, and we noticed that the cancer cells influenced the surrounding hypertrophic cells exactly in the same way as the hypertrophic cells had before influenced the surrounding normal cells.

These observations on the growth of young tumours, as was demonstrated in 1924 at the cancer congress in Strasbourg, bear out the old view of Virchow. It must be of great value to show in another way the influence of tumour cells upon the surrounding living cells of the organism.

In the first part of this paper I demonstrated that young (regenerating) epithelial cells, in certain circumstances, are very susceptible to tumour formation. On the strength of that observation I made the following experiment: Mice were tarred on the epilated skin until there appeared a few little papillomata, then we stopped applying the tar. A few days afterwards we made two little scarifications, one which was in contact with the tumour, the other at some distance for the purpose of control. We marked the position of these wounds by rubbing in Chinese ink, and after two or three days they were healed. Only a small black line under the new epithelium showed the place where the fine small scalpel had cut through the upper part of the skin. The little healing wound, which either touched the tumour or very nearly did so, showed some interesting changes. The whole mass of new epithelial cells in this wound changed into hypertrophic growth. We never saw in scars that were not in contact with a tumour changes of the same extent. There must be an influence of the tumour cells on the cells of the scar. We know that these cells were very liable to become neoplastic, and therefore it was possible to show this influence clearly. Just as we have seen in a papilloma, the surrounding cells were predisposed to hypertrophic, and afterwards real, tumour growth.

Summary.

1. Injury may have a direct influence on tumour genesis in an extensive area of epithelial cells that are susceptible to tumour formation.

2. Former experiments have made it probable that in the earliest stages of tumour formation the peripheral cells may have an influence on their immediate neighbourhood. When we effect contact between the youngest tumour cells and cells which we know are very susceptible to develop a tumour, then we can clearly see the direct influence of the tumour cells on the other cells of the organism.

It will be the purpose of cancer study to obtain a better insight into these intercellular activities.

* Read before the Royal Society of Medicine, Pathological Section, March 14th.

SEQUELAE OF ENCEPHALITIS LETHARGICA:

NOTES ON 128 CASES.

BY

CHARLES M. SMITH, M.A., M.D., D.P.H.,

CLINICAL OFFICER, PUBLIC HEALTH DEPARTMENT, GLASGOW.

DURING the spring and summer of 1924 there were under my care in Belvidere Fever Hospital, Glasgow, 143 patients suffering from encephalitis lethargica. Of 132 patients who were discharged from hospital, 128 were examined twice within a year at roughly six-monthly intervals.

The Degree of Impairment.

During the acute attack the cases were divided on a clinical basis according to the outstanding clinical feature—namely, lethargic, choreiform, myoclonic, psychotic, hypergalgesic, ophthalmoplegic. They were also classified according as the attacks were mild or severe, and these classifications were used to ascertain what correlation, if any, existed between the degree of impairment and the type and severity of the original attack. The results of examination a year after the attack are embodied in the following table.

Group.	Type of Attack.		
	Mild.	Severe.	Total.
I. Cases with no impairment	37	12	49
II. Cases with slight impairment (working or attending school, but with difficulty)	28	13	41
III. Cases with marked impairment (unfit for work or school)	7	21	28
IV. Cases with very marked impairment...	—	10	10

It will be seen that there was a fair degree of correlation between the original type of attack and the degree of impairment that followed; that the mild cases more often recovered, and that the severe cases more often were impaired. It would also appear that a higher proportion of attacks with a "positive" bias—using Walshe's classification[1]—were followed by impairment, when compared with those of a "negative" character.

The Two Main Types in Cases with Marked Disablement.—Where the sequelae and degree of disablement were marked two classes could be recognized.

A. The "Restless Naughty Child."—In this class the most constant features are insomnia, nocturnal restlessness, asthenia, pallor, psychic changes, and tics. During the day the child is restless and fidgety, "constantly on the move," as the parents say. He is very often noisy, irritable, nervous and easily frightened, bad tempered, impudent, and lacking in respect.

One boy had on several occasions threatened to commit suicide; in the street he would address strangers with complete familiarity and frequently behaved in a cruel manner to his younger brothers and sisters. As tested by the Binet-Simon scale there was no impairment of intelligence, in fact, there was a tendency to precocity.

In the mental processes of these patients, however, a characteristic impairment is to be found. They cannot maintain concentration on any one subject for any length of time; it is as if the mind, like the body, partook of the general restlessness. At night they are very troublesome; they roll, turn and toss about in bed, stand up and stamp, spit, sing, whistle, shout, clap their hands, and make peculiar noises—grunting, "cheeping," clucking, and blowing. One boy wanted to sharpen something with a knife all night long. This continued to a late hour until exhaustion brought sleep which lasted until late in the following forenoon. In a boy it was reported that on alternate nights the insomnia was absolute, the entire night being spent in restlessness and excitement; in the intervening night he slept heavily for about twelve hours.

In the worst example of this kind, a boy of 6 years, there was a striking degree of precocity combined with very definite evidences of moral degeneration. At one time he contracted a habit of vomiting up mouthfuls of undigested food, which he would, if allowed, consume. He would also attempt to embrace everyone who came near. A year after the original infection he was in another hospital, and deterioration was so marked and he was so difficult to deal with that removal to an asylum was being contemplated.

Nineteen patients, most of whom were between 7 and 14 years of age, fall into this class of the "restless naughty child."

The kind of attack which was by far the most productive of these sequelae was the severe choreiform type. Of a total of 35 children dismissed from hospital, 18, or 51 per cent., had developed these changes.

B. The Parkinsonian.—A feature of the Parkinsonian syndrome is that the same sluggishness which qualifies the thinking and movements of these patients affects also their conative faculties. They have little or no initiative. In the advanced stages they will sit for hours motionless. In less advanced cases it is frequently reported that they will "stay indoors and show no desire to go out." A year after the attack nine patients showed features of the Parkinsonian syndrome to a marked degree, and seven were then in other institutions; in all the condition developed in less than six months after the original attack; in one it appeared immediately after, and in most within one to three months.

In these patients the most common features of the syndrome were muscular rigidity, bradyphrenia, bradykinesia, etc., and salivation. Tremors were uncommon, only one example being noted—a slow rotatory movement of the head. The muscular rigidity was generalized except in one instance—a boy of 11 years, in whom rigidity with a slight degree of paresis was confined to the right side of the face, the right arm, and right leg. In a woman aged 53 the rigidity was so great that the mouth could not be opened nor the tongue protruded, and considerable effort was required to raise the eyelids. In one young woman with advanced Parkinsonism a disturbance of the respiratory mechanism developed; it was due probably to spasticity of the laryngeal muscles, which has been rarely, if at all, described. Respiration was accomplished by short inspiratory gasps, which were followed by noisy forcible expirations—almost as if she were attempting to blow out a light.

The ages of the subjects in this group ranged from 11 to 53 years. Two boys, aged 11, had muscular rigidity, bradyphrenia, bradykinesia, etc., all to a marked extent. The initial attack in all these cases was severe. In eight patients Parkinsonism had developed only to a slight extent. The most common elements in this group were the typical facies and some degree of bradyphrenia, bradykinesia, insomnia, and asthenia. Muscular rigidity was, in these patients, confined to the face. The original type of infection, with one exception, was severe.

The Signs and Symptoms.

The following is a list of the signs and symptoms observed a year after the attack in all patients manifesting sequelae. The total number of cases examined was 128.

Sign or Symptom.	No. of Cases.
Insomnia	55
Asthenia	46
Day drowsiness	31
Psychic changes	24
Nocturnal restlessness ...	21
Parkinsonism	17
Pain	17
Hyperreflexia	17
Hyperkinesis	16
Eye symptoms:	14
Paresis of accommodation	14
Anisocoria	10
Ptosis	5
Blurred vision	4
Diplopia	3
Squint	2
Myosis	2

Sign or Symptom.	No. of Cases.
Tics	13
Pallor	13
Restlessness	11
Headache	11
Pareses	7
Neurasthenia	6
Constipation	5
Adiposity	5
Speech changes (excluding bradyphasia)	6
Abnormal gait (excluding brndybasia)	5
Nocturnal enuresis	3
Absent-mindedness	3
Bulimia	2
Furunculosis	2

This table affords some conception of the varying range of signs and symptoms that may be presented a year after the attack. The two symptoms which head the list, insomnia and asthenia, were the prominent features in those patients who were slightly impaired, but still able to follow their occupation, although with more or less difficulty. None of the patients required to be certified mentally deficient.

These notes give some impression of the degree and form of disablement in 128 cases caused within a year by an attack of encephalitis. All degrees of disablement, and many different and complex types, were observed. Disablement—including the slighter forms—existed in 62 per cent., while incapacity to resume work or school was found in 30 per cent.

These figures agree closely with the results of a similar inquiry made in Glasgow. A series of 334 patients who contracted encephalitis lethargica in 1924 was investigated fifteen to eighteen months after the attack, with special reference to the capacity for work. It was reported that 36 per cent. were unfit for work. Some of these patients had been treated in hospital and some at home.

It has been recognized for some time that the existence of disablement due to encephalitis lethargica constitutes a problem which public health authorities have to face. The problem has been tackled in Scotland, as in other countries, by the establishment of a hospital unit where cases are admitted for special investigation and research.

HEALED FRACTURES OF TRANSVERSE PROCESSES.

BY

OWEN L. RHYS, M.D.,

RADIOLOGIST, ROYAL INFIRMARY, CARDIFF.

In 1910, and again in 1913, I published a few cases in the BRITISH MEDICAL JOURNAL of what I termed pseudo-fractures of the lumbar transverse processes. In nearly all there was no history of injury, and I suggested that they were attempts at rib formation by the costal element in connexion with the transverse processes. Dr. Reginald Morton also emphasized the importance of these conditions from the medico-legal standpoint.

Since then I have seen scores of cases in which gaps, and wide displacements, appear in several processes, sometimes on both sides of the vertebrae, where no injury had occurred.

In this district, where back injuries and fractured spines are common, the problem of deciding whether trauma has anything to do with the condition shown in a radiograph arises almost every day. In some of the widest separations I have seen, in which perhaps four processes have been displaced downwards for an inch or more, there has been no strain or blow, but I have now and then found a similar condition below the seat of an injury, and in several cases the man has placed his finger on a spot as the seat of pain, which has proved to be exactly over a separated process. In such cases I always attribute the separation to the injury. The case here illustrated by diagrams taken from radiographs is interesting because it for once answers a question which has often been raised—namely, if these processes have been fractured why do they not follow the usual method of healing with callus formation?

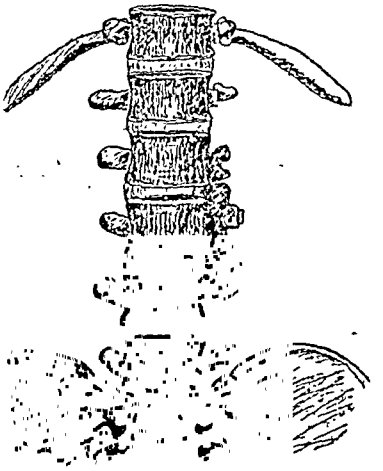

FIG. 1.

FIG. 2.

A Welsh collier, aged 55, was struck in the left loin by some falling material. He was much bruised and had a small wound. Some weeks later a radiograph showed the first four left lumbar transverse processes separated as shown in the diagram (Fig. 1). The man resumed work, and, after a time, did full collier's work for some months. Then, after an unusual twist, he had pain in the left loin and gave up work. I took the radiograph (Fig. 2) some two and a half years after the first accident. The first process remains as before; the remaining three have fused together in a mass of callus about four inches long and one inch wide, running parallel to but separate from and behind the bodies.

I have previously seen slight attempts at callus formation in single fractured processes, but never anything extensive as this.

On the vexed question whether strain, as distinct from direct violence, can fracture these processes, I can only say that I have not been satisfied in any case that it has occurred. I think it more likely that muscle or muscle attachment would give before bone. Before I accept even direct violence as cause I expect the following conditions to be fulfilled.

1. A definite history of a blow over the site of the suspected fracture. I have seen a workman awarded compensation because a radiograph showed a separated second lumbar transverse process. His injury was a fall on the buttocks on a smooth floor, whilst pushing a wheelbarrow. His symptoms were those of sciatica.

2. The lesion must be unilateral. It is inconceivable that an injury could fracture transverse processes on both sides without also fracturing the spinous process.

3. The immediate after-history should be reasonably consistent with the man having had a severe blow. Considerable force is necessary to break a bone covered as these processes are covered, and I should expect very definite evidence of bruising, and probably a wound. So much depends upon the man, that his capacity for working on varies enormously. Some of the old Welsh colliers have extraordinary powers of bearing pain, and will manage to walk home after such an injury, but any attempts at working or stooping would naturally be extremely painful.

AN INFLUENZAL CONDITION SIMULATING THE ACUTE ABDOMEN.

BY

R. ST. LEGER BROCKMAN, M.CHIR., F.R.C.S.,

ASSISTANT SURGEON TO THE SHEFFIELD ROYAL INFIRMARY.

THE responsibility of deciding whether a case is one needing the immediate aid of surgery, or whether the abdominal signs are the mask of a medical condition, is no uncommon experience. When faced with this type of case the medical practitioner will be alive to the possibility of pneumonia or of a sudden pneumothorax, of uraemia, and of the nervous crises of tabes and pernicious anaemia; but when all these have been reckoned with there remains another class not infrequently submitted to needless surgery.

Many can call to mind a case in which the abdomen was opened under the impression that an acute catastrophe had taken place, but no gross lesion of any organ could be discovered, only a slight amount of free fluid, sometimes blood-stained, scattered petechial haemorrhages, and small bags of jelly-like lymph. After careful search a more or less normal appendix has been removed, and the surgeon has closed the abdomen with no small degree of secret chagrin.

During the last two years I have seen in consultation a series of fifteen cases, all remarkably constant in general type, with marked signs and symptoms pointing apparently to some acute surgical intra-abdominal lesion. In one instance I performed laparotomy on the diagnosis of acute intestinal obstruction. I found the free fluid, the jelly-like lymph, and the subperitoneal petechiae. There was in addition, in the lower portion of the ileum, a persistent contraction ring with distended gut above and collapsed intestine below. No organic cause of any nature could be discovered. This man recovered in spite of the treatment, whilst all the others have reached the same happy ending without the intervention of surgery.

These cases form, I believe, a definite clinical condition, which can mimic, as it did in this series, any type of acute surgical abdominal condition. Taking this case which I opened with the previous sporadic ones exhibiting similar intra-abdominal findings, and comparing all as regards their clinical signs and symptoms, I think that it is possible to offer a reasonable hypothesis for their cause and pathology.

The onset was sudden; vomiting of bile-stained material was an early sign, but was not persistent. The patient was seized with the most acute pain without any previous feeling of malaise or other warning symptom. In some the pain was in the upper abdomen, in others in the lower. The acute spasms of pain were intermittent, with intervals of comparative freedom varying from five to fifteen minutes. During the spasm the muscles in the affected area could be felt, and at times could be seen to go into a condition of cramp. During the attack there was board-like rigidity in the affected area which did not completely disappear with the pain. Palpation caused pain, but the patient complained before the pressure of the examining hand had reached the peritoneum. The tender layer appeared to lie in the muscles of the abdominal wall rather than in the peritoneum. It is a distinction which is not very easy to explain in writing, but it can be clearly observed in the clinical examination.

The severity of the pain was most marked, and the way in which it could wring a cry from strong men suggested, when seen for the first time, that an acute perforation of

a hollow viscus had occurred. These patients did not, however, lie still, as does one with acute perforation, but rolled about in pain; some of the patients insisted on getting into the knee-elbow position during the spasms. The abdominal respiratory movement was little if at all impaired in spite of the large degree of rigidity. This is a point which I believe is always of great value in diagnosis between a surgical abdomen and referred abdominal symptoms. It is a sign which I have before described as "the respiratory movement resistance-ratio."

The pulse rate in most cases was unaltered at the commencement of the trouble, the temperature was normal or even subnormal. The facial expression was in no way suggestive of an abdominal lesion, and was a valuable piece of evidence. In twenty-four to forty-eight hours the picture changed, and signs suggestive of influenza were manifest, whilst the pain had in large measure disappeared. It is with the cases in which an acute obstruction is suspected that most difficulty arises. It is hard to refrain from opening the abdomen in a doubtful case when two enemas have produced no result. The passage of intestinal contents may be arrested in three ways: by mechanical obstruction, by paralytic ileus, and by acute spasm of the intestine, or what is called spastic ileus. The one case which I opened was of this type. Its association with influenza has been noted by other observers. If this condition is suspected and two enemas have no result, then the correct treatment is to give an injection of morphine and follow this by another enema in half an hour. In my experience a good faecal result will follow this practice, and so prevent untimely surgery.

There appears to be a definite seasonal incidence, since these cases have mostly occurred during an epidemic of influenza. As happens with influenza, relapses were not uncommon in this series, in some of which the whole sequence of events was repeated after a fortnight or three weeks; in one instance of a girl who had severe vaginal and pelvic pain three attacks supervened.

In other cases of influenza pain of a similar nature has been felt along the course of the fifth cranial nerve, and in some this has been followed by a herpetic eruption over the area so supplied; in others an eruption has not appeared although the acuteness of the pain in the area has been just as marked. A true herpetic eruption was seen in only one of this series. In another case, however, which suggested an acute cholecystitis, in place of the ordinary vesicular appearance of the herpetic lesion a crop of petechial haemorrhages with the same characteristic spacing and distribution was later seen in the area of the skin of the abdominal wall affected by the pain. I have on one other occasion seen pain along the course of cutaneous nerves followed by a similar haemorrhagic manifestation of herpes.

In encephalitis lethargica, which also in some measure keeps pace with influenza epidemics, an intermittent painful spasm of the abdominal musculature is a well known feature.

The suggestion which is here put forward in explanation of the pathology of these cases is based on the work of Sir Thomas Lewis on the setting free of a histamine-like body in the skin by the use of antidromic nerve impulses. It is suggested that the influenza toxin or some ultramicroscopic virus associated with the disease causes a lesion of the posterior root ganglia. Instead of a toxic agent being set free in the skin, as it is in some instances as a result of such irritation, this happens at the nerve endings in the subperitoneal tissues, and so gives rise to the petechial haemorrhages and the free fluid which are the common pathological changes seen if the abdomen is opened in these cases.

Memoranda;

MEDICAL, SURGICAL, OBSTETRICAL.

PAPILLOEDEMA AND ARTERIO-SCLEROSIS.

DURING May, 1926, two patients were admitted to the ophthalmic ward of St. Bartholomew's Hospital complaining of failing vision.

CASE I.

A man, aged 52, had been in the hospital in June, 1925, when he complained of failing vision, and was found to have marked swelling of both discs, unaccompanied by haemorrhage or exudation. There was also well marked retinal arterio-sclerosis. Vision in both eyes was much reduced (< 6/60). The heart was slightly enlarged; the blood pressure was 260/160, and there was a trace of albuminuria. No nervous lesion was discovered. The Wassermann reaction was negative. He was discharged at the end of June, 1925, *in statu quo*.

On readmission in May, 1926, he had the same degree of papilloedema and of retinal arterio-sclerosis as before, but vision was still more reduced. His complexion was blotchy and unhealthy. The heart was not appreciably larger than before; blood pressure 260/140. There was no nervous lesion. The urine contained a heavy cloud of albumin, urea 1.65 per cent., and there was a scanty deposit consisting of a few white blood corpuscles, epithelial cells, and hyaline casts.

CASE II.

A man, aged 52, gave a history of failing vision (presbyopia) for four years. He was found to have considerable swelling of both discs with no haemorrhages or exudation. Arterio-sclerotic changes were well marked in both fundi. Vision in both eyes was 6/12. The general examination revealed that his health was good. The heart was slightly enlarged; blood pressure 205/145. No nervous lesion was discovered. The urine contained a trace of albumin; urea 2.6 per cent.; a moderate deposit contained a few white blood corpuscles and a few epithelial cells.

In both these cases there was well marked papilloedema of a type which, ophthalmoscopically, was indistinguishable from that seen in cases of cerebral tumour. There were no haemorrhages and no exudation. The clinical diagnosis in each case was persistent hypertension, and the diagnosis lay between hyperpiesia and chronic interstitial nephritis. The high diastolic pressure in both cases is in favour of chronic interstitial nephritis, in which the diastolic pressure tends to be rather higher than in the purely vascular group. In the first case the presence of a heavy cloud of albumin was also in favour of chronic interstitial nephritis. In both cases there was absence of symptoms of renal function failure or renal toxaemia; there was no loss of weight in Case II (slight in Case I); no digestive disturbance, no micturition changes, and no secondary anaemia. In both cases the kidneys could concentrate well. There were no red blood cells or appreciable excess of white blood cells in the urine.

Dr. Geoffrey Evans has shown that arterio-sclerosis of a certain form is a constant pathological change found after death in vessels of patients suffering from persistent hypertension during life. In both cases, therefore, the pathological diagnosis of diffuse hyperplastic sclerosis can be made. But whereas Case II belongs to the group of essential hypertension, or hyperpiesia (German arteriolo-sclerosis), the first case belongs more probably, to the group of chronic interstitial nephritis, or nephro-sclerosis gravis; Volhard's form of malignant hypertension). The striking point is the amount of papilloedema. In both cases, as has been stated above, this was present in the degree which is seen in cases of pronounced increased intracranial pressure, and, indeed, it was indistinguishable from that which occurs in this condition. Papilloedema does occur in renal retinitis, but rarely to such a degree, and is very seldom unaccompanied by other evidence of renal retinitis—such as cotton-wool patches and haemorrhages. Further, in Case II the renal origin of the disease can be, with a good deal of certainty, excluded.

It is noteworthy that the amount of papilloedema in Case I remained unchanged after one year.

It is suggested that the papilloedema in these cases is associated with persistent hypertension and arteriosclerosis.

These cases are published in order to call attention to this association, for by following up such cases it should be possible to tell if Bright's disease in any form develops.

My thanks are due to Mr. R. Foster Moore and Dr. Geoffrey Evans for their assistance in compiling these notes.

SPONTANEOUS RUPTURE OF THE HEART.

WE desire to place on record the following notes and *post-mortem* findings of a case of sudden death in a woman aged 79.

Mrs. N., who had previously complained of breathlessness and flatulent dyspepsia, rose from bed as usual at 7 a.m. She was heard to give a scream and to fall on the floor. The relatives saw her at once and replaced her in bed. She was unconscious, and efforts were made to give her restoratives. When seen half an hour later by one of us (J. R. S.) she was dead. It was thought that death had occurred within fifteen minutes.

Post-mortem examination revealed fairly healthy conditions of all organs with the exception of a number of small gall stones, and a spleen weighing 9¾ oz. relatively soft and friable. The pericardium was tense and distended, and, on incising the pericardial sac, blood clot weighing 9¾ oz. was found forming a cast round the heart. The blood clot was nowhere adherent except at three places about a quarter of an inch in diameter over the anterior aspect of the heart muscle. At the lowest of these places the clot dipped down into the fatty heart substance. On careful inspection of the heart and large vessels no opening for the escape of blood was found except as later stated.

The heart weighed 15½ oz. The mitral valve cups were thickened. The chambers of the heart were empty of blood clot with the exception of a small clot in the right ventricle. The muscle was pale and flabby, and the anterior wall of the right ventricle seemed to be almost entirely replaced by fat and fibrous tissue. This part was translucent, and a small oval aperture with fairly smooth edges could be seen, the position of the opening being in the lower half of the right ventricular wall a quarter of an inch from the interventricular septum.

This portion of the right ventricle was submitted for further examination and reported on as follows: "There is an actual perforation of the heart wall, leading into the pericardium, and sections show that the cardiac muscle is very atrophic and actually deficient in several places, especially in the region where the macroscopic hole occurs. The coronary artery supplying the area is arterio-sclerotic and shows narrowing of its lumen and partial blocking in many places."

A number of similar cases have been already reported in the BRITISH MEDICAL JOURNAL (1924, vol. ii, pp. 373, 465, 669; 1925, vol. i, p. 262), and it is interesting to note that in the seven cases reported (including our own) six occurred in female patients. In every case except that here recorded the tear was found in the wall of the left ventricle.

A RISK OF LIQUID PARAFFIN IN CHRONIC CONSTIPATION.

MINERAL oils have become so suspect as a cause of cancer of the scrotum that it seems questionable therapeutics to prescribe paraffin in cases of chronic constipation. Pure medicinal petroleum, as liquid paraffin is labelled, may be as perfect a preparation as it is possible to get, but it cannot be gainsaid that when expelled, in due course, from the rectum it is a dirty oil, and thus the anal region is kept in constant contact with dirty oil. Owing to the arrangement of the muscle at the anus the skin in this region presents a stellate arrangement with the anus as centre, and if, by any cause, the skin of the region becomes inflamed, folds and fissures are liable to develop which are cleaned with great difficulty. Thus a condition comparable to that obtaining on the scrotum is easily set up. Further, in many people the oil seeps through the anus and soils the underclothing, and if the patient continues to swallow the paraffin the whole of the buttocks may be in constant contact with oil.

My attention was first directed to paraffin as an irritant to this region by the following case:

A man, aged 48, consulted me for eczema ani, from which he had suffered for over twelve months. He had been the subject of constipation since childhood, and during the past two years had taken liquid paraffin with some success. Twelve months ago he thought the anal region felt wet, though the underclothing was not soiled. Later the part became itchy, and when I saw him the perianal region was the seat of a weeping eczema and inflamed with a stellate condition leading to the anus. Lotion was prescribed to settle the inflammation, with, however, little success. I then stopped the paraffin and prescribed compound liquorice powder as an aperient. The eczema began to settle almost immediately, and in a few weeks he was quite recovered.

Since this experience I have had five cases of eczema ani, three of whom were the subjects of chronic constipation and were taking paraffin. In all the paraffin was stopped before commencing treatment for the skin condition.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

OXFORD AND READING BRANCH.—OXFORD DIVISION.

Surgical Treatment of Gastric Ulcer.

AT a meeting of the Oxford Division at the Horton Infirmary, Banbury, on April 22nd, with Dr. W. COLLIN in the chair, Professor GEORGE E. GASK, director of the surgical unit St. Bartholomew's Hospital, delivered a British Medical Association Lecture on gastric ulcer.

Professor Gask said that there had been gradual improvement in the surgical treatment of gastric ulcer in association with the better diagnosis of this condition. The first great advance had followed the invention of test meals, which were still valuable, though sometimes disappointing. A further stride had followed the introduction of *x* rays, and the accuracy of the radiographical diagnosis as verified by operation had been found to be as high as 88 per cent. Professor Gask illustrated by lantern slides the diagnosis of ulcers in various parts of the stomach following the administration of a barium meal, and insisted that *x* rays must not be allowed to supplant careful clinical examination, with especial reference to such clinical points as the duration of the pain and the habits of the patient. Such examination should include the study of the blood, the stools, and the gastric contents after the exhibition of a test meal. Professor Gask thought it was most necessary for the surgeon to be present at the radiographical examination. He said that the type of gastric ulcer had changed in the last twenty years; it seemed that the acute type formerly found in chlorotic girls had disappeared. Surgical treatment was urgently indicated in cases of perforation, pyloric stenosis, carcinomatous implantation, and sometimes in haematemesis. Although medicinal treatment might sometimes cure the condition there was often no improvement, and then more active measures were required. It was undesirable to delay so long that the patient was worn out by the pain. With regard to the type of operation, gastro-enterostomy was the simplest and most useful when there was pyloric obstruction from old ulceration. Good drainage was obtained, but it was necessary to remember the occasional failure, and the possibility of the return of pain and ulceration. Professor Gask briefly discussed the operation of pyloroplasty advocated by Professor Finney of Baltimore. It was difficult to adjudicate between the relative values of gastro-enterostomy and gastrectomy, but the latter appeared to be gaining the day. Much depended on the site of the ulcer. For instance, when it was high up, on the lesser curvature—in which situation medical treatment was of little or no avail—some form of gastrectomy, even though it meant sacrificing a large part of the stomach, was the operation of choice. The cause of gastric ulcer was still undetermined, and consequently all treatment at present was empirical; it was possible that under better social conditions the disorder might be eliminated. In the meantime, as far as operations were concerned, the immediate results of large gastrectomy were good, but only time could show what the ultimate results would be. Some of the patients on whom gastrectomy had been performed had subsequently developed severe anaemia. Professor Gask's dispassionate survey of gastric ulcer and its treatment was much appreciated; it was discussed by several members. A vote of thanks, proposed by Mr. WATERFIELD and seconded by Mr. HUGH WHITELOCKE, was carried with acclamation.

Dr. PENROSE showed four cases.

(1) A woman, aged 53, had first sought advice in January, 1925, for pain in the neck and throat. Marked jaundice had come on suddenly three days before, but the urine had been dark for some weeks. There had also been loss of appetite for some weeks, but no pain or vomiting. The jaundice had continued, but the patient's weight, which had gone down at first, was now the same as when she was first seen. Attacks of diarrhoea began toward the end of 1925 and had continued subsequently. Chronic pancreatitis, malignant disease, and gall stones had been suggested as the diagnosis.

(2) A man, aged 50. This patient had had attacks of loss of consciousness for two years, tending to be increased by worry.

He had always been sallow, and venereal disease was denied. Hystero-epilepsy, heart-block, and Addison's anaemia had been suggested.

(3) A man, aged 30, who presented signs of pyloric obstruction and subsequent anaemia, had at one time shown evidence of early combined degeneration of the spinal cord, but this improved under treatment.

(4) A man, aged 35, had had a severe haematemesis while under treatment in hospital for myelitis. Another case was reported of a man, aged 65, who had had a fatal haematemesis following a three months' history of indigestion. At the *post mortem* a small ulcer was found in the stomach with a pin-hole perforation into a vessel.

Reports of Societies.

HYPNOTIC DRUGS OF THE BARBITURIC ACID AND SULPHONAL GROUPS.

At a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on May 10th, Dr. GEORGE GRAHAM presiding, the subject of the clinical and pathological effects of hypnotic drugs of the barbituric acid and sulphonal groups was introduced by Sir WILLIAM WILLCOX, who incorporated in his remarks some work on the historical and statistical side by Dr. HELEN YOUNG, while Dr. F. A. PICKWORTH described experimental researches on the effect of these drugs on animals.

Sir WILLIAM WILLCOX said that he had for a long time been impressed by the potent action of these drugs when given in a single large dose or in doses repeated for several days or longer. Definite signs of organic paralysis had occurred after administration, passing away on the discontinuance of the drug, and marked mental symptoms, depression, and hallucinations had also been observed. The dangers of these drugs had not been sufficiently realized by the medical profession or the public, and the danger was accentuated to-day when, in addition to veronal, medinal, luminal, and other drugs of the older series, there were placed on the market a large number of new barbituric acid compounds and derivatives whose fancy names concealed their composition, so that unless minute scrutiny was given to the pamphlets issued with these drugs their nature was liable not to be discovered, and the glowing descriptions of their therapeutic actions did not make it plain that they were dangerous unless used with the greatest care. Until the introduction of veronal in 1902 the sulphonal group of drugs held a prominent position as hypnotics, but since then the members of the barbituric acid group had come to the fore. The barbituric acid drugs in therapeutic doses acted rapidly, and were fairly certain hypnotics. A single therapeutic dose was usually followed by a satisfactory period of natural sleep, and no marked after-effects followed when the therapeutic action had passed away, which should be in from six to twelve hours. In cases of *insomnia* the use of these drugs was very apt to lead to the formation of the hypnotic habit. It was a mistake to prescribe these drugs in repeated doses for painful neuralgic conditions; they were hypnotics, not analgesics. The members of the sulphonal group also were powerfully acting hypnotics, but with these the therapeutic effect of drowsiness and sleep might not commence for several hours after administration, and this delay and uncertainty had prevented drugs of this class from coming widely into use, though the same caution must be given with regard to them as with regard to the barbituric acid group.

The symptoms observed after taking doses larger than the therapeutic dose of members of the barbituric acid group—or, in cases of idiosynerasy, after taking the therapeutic dose—were headache, vertigo, and ataxia, occurring within a few minutes, and within an hour or so the patient might fall into a deep sleep from which he could only be roused with difficulty. Albuminuria of a mild type might occur and be associated with the presence of casts. There might be incontinence of urine or faeces. A rather common occurrence with overdose was the development of bronchopneumonia, which came on very suddenly, and might be of the massive type; nearly all the fatal cases had bronchopneumonia. With veronal the average dose in the fatal cases was 50 grains, but death had occurred after as small a dose as 10 grains, though other factors were probably present, and, of course, recovery had taken place after much larger doses than 50 grains. People who took veronal every night were liable to show, not only certain mental, but certain moral changes, to get exceedingly depressed, with suicidal tendencies, and to have hallucinations, commonly visual, and sometimes delusions. The veronal subject showed symptoms it was difficult to distinguish from chronic nerve disorder; he had the same kind of speech that was found in general paralysis of the insane, also diplopia and visual paralysis. The kidney had a remarkable effect in picking up these drugs, and in some of the analyses in cases of veronal poisoning two or three times as much veronal had been found in the urine as in the blood. A characteristic feature with luminal was haematoporphyrinuria. To the sulphonal group the same warnings applied. The drugs of this group had been very carelessly administered because they were thought to be harmless, but addiction did occur.

In conclusion Sir William Willcox exhibited some analyses made in cases of veronal poisoning, and also gave statistics of the deaths from poisoning by barbituric acid drugs since the first case in 1906. The number of deaths rose by 1915 to over 20 annually, and did not decrease until, in 1918, the drugs were placed in Part II of the Poisons Schedule, after which the annual number of deaths dropped to about 8, but in the last year or so it had risen again, and in 1925 the number was 25. These drugs should only be given by prescription, marked "not to be repeated," the prescription to be retained by the pharmacist, and the total number of doses ordered should not exceed six. The patient should be warned against the daily use of the drugs, and it would be a safeguard to avoid giving the drugs on consecutive days. The medical profession should also be seriously warned against the widely circulated advertisements or drugs of the barbituric acid group. These advertisements frequently recommended the drugs for continued administration without calling attention to the toxic effects which might result from their use. The continued introduction of new barbituric acid derivatives, which must of necessity have had only an inadequate clinical trial, increased the danger of the position.

Dr. F. A. PICKWORTH then gave an account of some experimental researches on the effect of these drugs on animals, accompanying it by an exhibition of histological specimens. This work was initiated by the late Sir Frederick Mott, with whom Dr. Pickworth collaborated, and it went to prove that the clinical symptoms of paralysis of the central nervous system following the use of these drugs could not be regarded as a mere temporary intoxication of a harmless type, but were associated with definite objective changes of a serious nature. Dr. Pickworth entered into much detail with regard to the pathological changes found in the tissues of animals—monkeys and cats—after the administration of these drugs.

Dr. W. E. DIXON said that it was difficult to explain why persons suffering from drug poisoning should get pneumonia. What was the mechanism? Was it that the leucocytes were paralysed? Veronal did not go to the lungs, and yet a lung lesion was produced. He also remarked on the selective action of the drugs in causing paralysis in one limb rather than in another.

Dr. F. PARKES WEBER mentioned an interesting case of haematoporphyrinuria from veronal poisoning. It was in a woman who for two months had been taking 5 grains of veronal almost nightly as a hypnotic. The urine for a considerable time was red or red-brown in colour, and the colour disappeared gradually within two weeks after discontinuance of the veronal. He also mentioned an extraordinary bullous eruption with jaundice occurring in a child who had been given therapeutic doses of luminal for chorea.

Dr. P. HAMILL referred to the great difficulty of diagnosing veronal poisoning. He asked Sir William Willcox whether he had actually observed similar toxic phenomena with the new drugs of the barbituric acid series, because in a certain number of cases drugs of this type did relieve pain in a remarkable manner. Professor GUNN remarked that veronal lowered the bactericidal power of the blood. Dr. STOLKIND mentioned a case of medinal poisoning in

which the effects were the same as those seen with veronal. Dr. DOROTHY HARE said that in giving luminal in epilepsy she had never exceeded 2 grains, but recently in one case, after a long spell of treatment, she noticed a decided lethargy, which she at first thought to be a mild attack of encephalitis lethargica, but now wondered whether it might be mild luminal poisoning.

Sir WILLIAM WILLCOX said that luminal undoubtedly was very toxic, and would cause the same changes as had been described. Luminal and the members of the barbituric acid group were not cumulative in the material sense, for they were rapidly excreted by the kidney, but the effects on the nervous system were cumulative. Why pneumonia occurred in veronal poisoning he did not know. He had always put it down to the abolition of the reflexes in the upper respiratory tract, which led to the passage of foreign substances into the lung. As for the new drugs of this group issued under different names, he believed that they did cause toxic symptoms; he had had several letters to that effect, and had himself seen cases.

DEVELOPMENT OF SCHISTOSOMA MANSONI.

AT the annual general meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine on May 4th, the President, Professor R. T. LEIPER, F.R.S., in the chair, Dr. J. B. CHRISTOPHERSON read a paper by Dr. P. H. J. LAMPE of Dutch Guiana on the development of *Schistosoma mansoni*.

Dr. Lampe had made an intensive study of the development of this parasite in South America. He had found that the miracidium crept slowly out of the egg shell, which ruptured on reaching water; he had never observed the dilatation seen in the bladder form. This miracidium could not live for more than forty hours without entering a snail. The intermediate hosts were two species of *Planorbis*, and about 15 to 18 per cent. were infected. Most of the miracidia disappeared into the buccal and mantle cavities of the snail, and Dr. Lampe believed that infection occurred normally through the mouth. In the snail, as the result of the usual asexual multiplication, an enormous number of cercaria were produced—in one case estimated there were about 170,000 formed at the rate of over 2,500 daily. Although Dr. Lampe had been able repeatedly to infect experimental animals through the skin, the penetrating cercaria were difficult to find, and he suggested that they passed very rapidly to the subcutaneous tissue; when a wound was present they were more easily traceable. The cercaria did not make use of the hair follicles or pores to gain admittance, but actually severed and lifted the skin. In the host he found that the larvae, after piercing the skin or mucous membrane, rapidly reached the subcutaneous tissue and then the veins and the right heart, where they might be found within six hours of infection. Once in the circulation they passed to the lungs, where they left the branches of the pulmonary artery and then penetrated the stroma between the alveoli, especially at the base of the lungs. Only a few parasites were able to leave the lungs, and these pierced the visceral pleura and reached the diaphragm three days after infection. At this stage more died, but some passed to the liver through the adhesive connexion with the diaphragm; in the stroma development was very rapid, and in a few days the cercaria resembled adult parasites. From the liver the young parasites proceeded to the portal system. Dr. Lampe believed that full-grown parasites might not infrequently be found in the lungs, as he was unable to explain the important alterations in that organ on any other hypothesis.

Professor R. T. LEIPER drew attention to the fact that although Dutch Guiana was infected with *Schistosoma mansoni*, British Guiana, though immediately adjacent to it, escaped. The two countries were separated by a rapidly flowing river, and the inhabitable portion of the British territory was largely land reclaimed from the sea, and was accordingly salty. He believed that this salt prevented the development of the snail in that country. He thought that it was still premature to consider as definitely settled the course which the larvae adopted after entering the skin. There were two schools of thought. One believed that the somewhat amoeboid cercaria could pass through the lungs and so return to the heart and reach the liver by means of the blood stream. This was the more generally accepted view, but Dr. Lampe's belief that the larvae passed from the lungs directly through the diaphragm to the liver might also be true. An analogous method of infection was known, not only in the case of the common liver fluke of sheep, but in the lung fluke of man. It might well be that both methods of gaining access to the liver were possible.

TREATMENT OF URETHRAL STRICTURE.

AT a meeting of the Brighton and Sussex Medico-Chirurgical Society, on May 5th, the President, Dr. E. RIVAZ-HUNT, in the chair, Mr. F. E. FEILDEN gave an address on the treatment of urethral strictures, and demonstrated the old and new types of urethroscopes.

Mr. Feilden said that stricture of the urethra was a serious condition, but it was not seen so frequently now as a comparatively few years ago. For its efficient treatment it was necessary to realize that the bulb, where most strictures occurred, was the widest portion of the urethra and the external meatus the narrowest. Many strictures could be cured by a Kollmann's dilator. The best results in urology were only to be obtained by an intimate knowledge of the pathological condition. Strictures of the urethra in order of frequency were of inflammatory, traumatic, and congenital origin. Gonorrhoeal strictures were often multiple. A single stricture in the penile urethra was uncommon. Except after operation, strictures were rarely found in the prostatic urethra. About 75 per cent. of strictures occurred in the bulb, probably partly because this was the most dependent part of the urethra and gonorrhoeal discharge tended to collect here. Moreover, since this was the point of the fixed course of the urethra, the full force of micturition was directed hither, producing trauma, which resulted in infiltration of the mucosa. When the narrowing had progressed sufficiently to cause obstruction, the force of the urinary stream increased the chronic inflammatory reaction. In support of this view it was added that in cases of multiple strictures the narrowest stricture was situated nearest the bladder. Mr. Feilden thought that excision of strictures should be reserved for those due to trauma; in other cases it was unnecessary. It was probable that the incidence of stricture could be reduced if every patient with gonorrhoea, before being discharged as cured, was submitted to full dilatation. Greater use should be made of the urethroscope; some strictures could not be diagnosed without its aid. A gentle hand was most essential in passing urethral instruments. Unfortunate results were produced not so much by the introduction of organisms as by avoidable trauma of the urethral mucosa. Most strictures were amenable to treatment by dilatation. As regards silver instruments, the smaller sizes should be avoided, for they were likely to produce false passages. Silk-web bougies should be used up to 18, then steel bougies up to 12/15; the stricture should then be dilated up to 45 (Charrière scale) with the Kollmann pattern. In chronic retention, to avoid disaster, rapid evacuation of the bladder should never be allowed to occur. Strictures must not be forced, but some could be rapidly dilated at one sitting. Internal urethrotomy was a most satisfactory operation; often after internal urethrotomy and full dilatation no further instrumentation was necessary. If there was marked urinary infection or renal insufficiency, drainage of the bladder should precede the urethrotomy. In impermeable strictures or those resulting from trauma, the urethrotomy of Wheelhouse was the method of choice; it should be used in all cases of stricture of the bulb associated with periurethritis, periurethral abscess, extravasation of urine, or severe cystitis. In elderly patients with recurring epididymitis a bilateral vasectomy might be performed with advantage. A malignant prostate closely resembled a stricture in that there was no residual urine in either case. Tabes, by producing bladder atony, might be the cause of an apparent acute or chronic retention. The infection behind the stricture must be treated concurrently with the stricture.

Reviews.

SLIT-LAMP OPHTHALMOSCOPY.

An introduction of the direct examination of the eye by ans of an efficient microscope and the slit-lamp has given ophthalmic surgeon a most refined and beautiful addi- nal mode of extending the field of his investigations. r those to whom the method is known by name, but to om its basis is mysterious, a reference to an observation ich most children make, with wonder, will provide a fficient explanation. Who has not seen a narrow ray of nlight coming through the shutters of a closed window, d seen that the air was full of moving particles brilliant the sun-ray? That in essence is slit-lamp examination of e eye. By means of an appropriate projection apparatus, e device of Gullstrand, a thin ray of light can be focused on and made to cut into the eye; and the illuminated ction which this ray makes against the rest of the dark d unilluminated eyeball can be examined with a binocular icroscope almost as though that section were on the age of the microscope. This mode of investigating patho- gical processes of the living eye, particularly in the rnea, iris, and lens, has been much exploited in the last w years, and some stimulus was given to it by the iddlemore Prize competition of the British Medical ssociation. There has just been issued a work by Mr. ARRISON BUTLER of Birmingham a valuable and most mplete *Illustrated Guide to the Slit-Lamp*[1] as applied to isease conditions in the eye. It is a fine piece of work, to ie making of which there has gone much careful observation nd accurate recording. The work is founded upon a series f lectures at the University of Oxford, together with the oyne Memorial Lecture and the Montgomery Lectures iven at Dublin University. But there is nothing discon- ected in the presentation of the subject in the volume nder review; it is no longer a series of lectures but a o-ordinate whole. Mr. Harrison Butler is not only to be ongratulated on his text, but also complimented upon is skill as a draughtsman, for, although he does not say o in so many words, we believe that the whole of the 58 illustrations in the text and the 21 additional figures n the five coloured plates are the work of his own hand. Many of these are very beautiful, almost fascinating; only n a few has the printer failed to do justice to the picture.

The use of the slit-lamp has brought no revolution to he methods or theories of ophthalmology; it has done nothing for medicine so amazing as did the introduction of he ophthalmoscope; nor has it changed the work of the phthalmologist as did the discovery of the objective method f investigating the refraction of the eye by retinoscopy. t is a refinement upon existing methods. Focal illumina- ion has been employed as long as the eye has been subject o examination; magnifying lenses were used so soon as they were made available; and the use of the condensing lens and the hand loupe will never be superseded. But the fine ray of light of the slit-lamp and the binocular microscope give an image of such detail and of such size that the new com- bination is as superior to the hand lens and glass as is a good oil-immersion objective with a well focused substage con- denser better than an old-fashioned triplet objective. In certain conditions the slit-lamp is of great value in dia- gnosis. To determine the existence of interstitial keratitis is not always easy by the usual methods; but with the slit- lamp there is a picture so typical that it cannot be mis- taken for anything else. The infiltration of the cornea is seen to be fundamentally associated with the posterior layers of the corneal stroma; and though, when the inflammation is at its height, the more anterior zones may participate in the process, yet this is secondary to the main focus in front of Descemet's membrane. The great thickening of the cornea is also notable. The appear- ance presents a marked difference from keratitis of the phlyctenular type. But its value is even greater in the diagnosis of sympathetic ophthalmitis, which causes the greatest anxiety to the ophthalmic surgeon. In eyes suspected of this disease Mr. Butler urges the imperative necessity for the use of the slit-lamp. A characteristic sign, shared with other forms of severe cyclitis, is the presence of cells in the vitreous, the retrolental space, and the aqueous. Later, keratitis punctata and nodular iritis appear. If in an injured eye there be some inflammation but no signs of cells in these parts, it is improbable that there is sym- pathetic disease. If, with other clinical signs, a cellular infiltration be evident, the eye is likely to be dangerous. Finally, if there be similar cells in the other eye, then the eye is sympathizing, and treatment is urgent.

The book is well printed, and, as we have noted, pro- fusely illustrated; it will be of great service to other workers in this field of clinical investigation.

WHOLESOME MEAT.

The central departments for health in both England and Scotland have made good use of the powers conferred upon them, under the Public Health (Regulations as to Food) Act of 1907, to make regulations for preventing danger arising to health from the importation, preparation, storage, and distribution of food and drink, and codes have been drawn up for both countries, equivalent in substance, though differing slightly in form, which lay down the action to be taken by meat inspectors on finding evidences of tuberculosis or other disease in the carcasses of bovine animals and swine. To all engaged in these responsible duties *The Principles and Practice of Meat Inspection*,[2] by Dr. GERALD LEIGHTON, should prove a reliable guide. Dr. Leighton describes the slaughterhouse and its methods. He cites in some detail the American federal system, under which pork is not microscopically examined for *Trichinella*, on the ground that no micro- scopic method is even approximately effective, and that the surest safeguard, to cook pork well, is within the reach of all. The subject of humane slaughter is carefully explored. The use of the hammer, the pole-axe, and the various shooting instruments is compared with that of the knife alone. The author's treatment of the question is impartial and he does not attempt to dogmatize, but from the facts presented by him the impression remains that there is no excuse for cruel ways of killing. The comparative anatomy of the different food animals is succinctly indicated, the distinctions between the respective cuts and organs being clearly figured and explained. The importance of the lymphatic system is recognized and the significance of glandular enlargements shown. Dr. Leighton sets forth the etiology and effects of the parasitic infections. He recounts the cryptic story of the ox warble-fly, pointing the moral with a vivid illustration of an ox-hide perforated by larvae. He tells of *Oestrus ovis*, of the liver-fluke and its trans- migrations, and of other meat-infesting parasites. In his section on bacteriology the refer[illegible] should help to dissipate some ascribes it in one of its forms t Gaertner, in the other to *B. botulinus*. He dismisses ptomaines as a practical cause of meat poisoning. "These poisonous amines," he quotes, "are only formed when putrefaction is far advanced, and when the food is in such a state as to be altogether repulsive." Descending into the underworld of the meat traffic he discusses the foetal carcass, emergency slaughter, fallen animals, and the meat which he names worst of all, that of cattle dead of septic parturient fever. Among his other topics of outstanding interest are the local and general frequency of tuberculosis in cattle and other animals, the relation of bovine and swine tuberculosis, the diseases of organs and special parts, tinned foods, and the inspection of fish, game, and poultry. Dr. Leighton's book is admirably illustrated. Though primarily addressed to meat inspectors, it may be cordially recommended to the perusal of all, whether medical practi- tioners, medical officers of health, or students for a degree or diploma in sanitary science, who are interested in the important subject with which it deals.

MALARIAL PSYCHOSES AND NEUROSES.

THE mental and psychic aspects of malaria have been largely neglected in the past, and the work of Dr. W. K. ANDERSON on *Malarial Psychoses and Neuroses*[3] is, therefore, welcome. The child of neglect, when its unfortunate condition once comes to be recognized, is rather liable to suffer from excessive attention and over-indulgence; the author states in his preface that the book comprises his "experience of mental and nervous conditions apparently arising from malarial infection," and that "it will be seen that very few syndromes are absent from the list." While acknowledging that it is more than high time for so important an aspect of this most widespread of tropical scourges to be properly dealt with, we think that it is a pity that no check should have been inserted to prevent an excessive swing of the pendulum.

Of the introductory chapters, that on malaria in history, though condensed into the short space of eight pages, is interesting, and the attempt to correlate the symptoms of malaria, in its acute and chronic forms, with sympathetic, parasympathetic, and endocrine action is ingenious.

The practitioner in the tropics is always taught to bear in mind in all cases of fever the possibility of malaria, owing to its protean manifestations and remarkable powers of mimicry, but at the same time to remember that all sojourners in a malarial district are liable to show parasites in their blood and not allow themselves to be led away by this fact to regard all conditions in which such parasites occur as malarial. The tropical reader of this work will therefore be less likely to interpret the association of malaria or the subsequent finding of malarial parasites in any particular syndrome as instances necessarily of cause and effect.

The work is interesting to read, for, though largely of the nature of a compilation or selection of cases culled from the medical literature of various countries, the author's comments upon them are both instructive and suggestive, though it is clear that in a certain number of instances the diagnosis of malarial origin of the symptoms is arrived at largely by exclusion. When, after the preliminary chapters on malaria in general, the author comes to treat of the psychoses and neuroses, subjects which he has made more particularly his specialty, he seems not only to be on surer ground, but also more guarded in his conclusions, though it is sad to hear that "there is reason to believe that many cases of this kind [mental confusion the result of malaria in the war] were shot for desertion before the nature of this class of case was adequately understood." He wisely concludes an interesting chapter on clinical dementia praecox with these words: "It would be hard to say whether the cases of this series which had remained ill beyond a year were cases of true dementia praecox with malarial infection added, or whether permanent brain changes . . . had resulted from the malaria. . . ."

The book attempts to prove too much; according to it there seems to be no symptom, hardly any combination of symptoms, which cannot be ascribed to malaria, and were the views given acted upon in tropical countries it would be the rarest event for a native criminal to be brought to justice, or at least to be held responsible.

When so close a resemblance is demonstrated between certain malarial infections and general paralysis, and even the actual production of the latter by the former, it seems strange that no mention is made of the treatment of general paralysis by malaria, if only to point out a possible danger. Perhaps it was not regarded as coming within the scope of this work, but it opens up an interesting question in therapeutics.

To the similarities and relations between alcoholism and malaria a whole chapter is devoted, and part also of the preceding one is on its medico-legal aspects. This will doubtless be eagerly read by those barristers called upon to defend the reckless motorist who, happening to have been at some time in a malarious district or to have served in the war, has foolishly substituted liquid for the customary solid lunch.

The book has been well produced; the print is clear, the text remarkably free from misprints, the figures and micro-photographs are good, and the coloured plates beautifully reproduced. Judicious pruning in the next edition would add considerably to the value of the book.

SHELL SHOCK AND AFTER.

IN *Shell Shock and its Aftermath*[4] Dr. NORMAN FENTON, associate professor of psychology, Ohio University, has presented a careful and systematic investigation of the cases of war neuroses among the American Expeditionary Force which came under his care in France, and what subsequent history after their return to America he has assiduously explored.

All too often, as Professor SALMON, who has written an introduction to this book, observes, the emotional reactions of human beings are examined in a single setting and under a particular kind of stress. It is the unique contribution of Dr. Fenton to provide a longitudinal review of his cases, examining not only the nature of the neuroses at the time, but following them up and demonstrating the persistence or reappearance of the psychoneurotic manifestation in adverse circumstances, and in other cases its disappearance under wise psychotherapeutic guidance. It is with the aftermath rather than with the initial state that Dr. Fenton is primarily interested; and the data he has been at such pains to collect are examined for the purpose of reaching some definite conclusion regarding the ultimate outcome of war neuroses.

Dr. Fenton's work was at first carried out at Base Hospital 117, A.E.F. He had there the opportunity of first-hand study of war neuroses. Since then on two occasions he was enabled to trace the after-histories of his cases in 1920, and again in 1924, and to study the process of rehabilitation in civil life. To this end the mental and physical make-up of a typical group of shell-shock victims were examined; their social and economic background; their behaviour at home shortly after their return to America; and then some years later. In this respect the correlation between the military classification of these cases and their subsequent readjustment to civilian life is of interest. Dr. Fenton finds a positive correlation showing the prognostic value of such classification.

The typical war neuroses, such as gas syndrome, exhaustion, concussion, anxiety, show the best recovery rate, except for gas neuroses; and the more pronounced constitutional types, psychasthenia, etc., rank lower. Dr. Fenton's studies convince him that one of the significant facts regarding the after-history of war neurosis is the relative infrequency of psychotic developments.

Dr. Fenton's book is highly interesting and most readable. His discussion of the nature of war neurosis shows that his point of view is not only that of a psychologist; he gives a broad survey of the underlying problems, physiological and social and psychological. Many illustrative tables accompany the letterpress.

[4] *Shell Shock and its Aftermath.* By Norman Fenton, Ph.D. With an introduction by Thomas W. Salmon, M.D. London: H. Kimpton. 1926. (Roy. 8vo, pp. 173; 12 figures, 1 plate. 12s. 6d. net.)

NOTES ON BOOKS.

DR. GROSSFELD undertook to write an introduction to a book on the analysis of foods[5] at the suggestion, as stated in the preface, of Geh. Regierungsrat, Univ.-Prof. Dr. phil., Dr. ing. h. c., Dr. ph. nat. h. h. c. J. König in Munster i. W. It brings together the various processes which are described in the larger textbooks as forming the daily work in the laboratory, and to present them in shortened form, but in sufficient detail to enable them to be carried out from the descriptions. The author has, he tells us, paid special attention to recent developments, and describes many new methods which do not appear in König's comprehensive work on foods; he would therefore

[5] *Anleitung zur Untersuchung der Lebensmittel.* Von Dr. J. Grossfeld. Berlin: J. Springer. 1927. (Sup. roy. 8vo, pp. xii + 409; 26 figures. R.M.22.50.)

to wish his book to be regarded as to some extent a ment to the third volume of that work. Of the more matter may be mentioned a method of analysing wines, ichlorethylene method of estimating the fat content of a simplified method of estimating the lecithin-phosphoric onstituent in eggs, requiring only small samples, a simpli- ethod of calculating the alcohol content when present in percentages, and the recently introduced pectin estima- which has proved of importance in connexion with the vation of fruits. In order to facilitate the often ous calculations involved in analytical work a number bles have been introduced dealing with the fat t, the nitrogen content, saponification, the refraction the sugar content, and many other matters. The first f the work deals with methods generally; the second part he analysis of the individual foodstuffs, their impurities dulterations; and the appendix includes sixty pages of

quito Reduction[6] is a small book intended for those— ularly laymen—who are engaged in antimalarial work in It includes a general account of the causal agents of ia, the biology, morphology, and habits of the mosquito, he main outlines of preventive work. Appendixes on the ing, preservation, dispatch by post, and the identification e Indian species of anopheline mosquitos are also pro- Any attempt to cover such extensive ground within so-limited must of necessity be sketchy, but the authors succeeded in providing an accurate survey of the main s in an antimalarial campaign in a manner which can be understood and digested by an intelligent layman. The (4s. 6d.) of such a small handbook seems to be rather and may prevent it securing the circulation it deserves.

Outwitting Middle Age[7] Dr. CARL RAMUS, author of *iage and Efficiency*, has provided a book for popular con- tion, which the preface assures the reader will change mature person's outlook on life by showing that the bogy iddle age, if resolutely faced, can be driven forward into eding future, the duration of which in years cannot be ated at present. Much information is given on many s, including the causes and prevention of middle age, facts t foods, the glands of internal secretion, rejuvenation and ach's and Voronoff's operations, the influence of drugs, ology, the climacteric, and historical cases of longevity, as Ninon de Lenclos and of two living people, one of them Adolph Lorenz, the famous Austrian orthopaedic surgeon, publicly stated in 1926 that when 67 years of age he under- the Steinach operation, and advised every man over 60 very man with early arterio-sclerosis to follow his example; Fanny Ward seems also to have been freely discussed in ress. The literary style cannot conscientiously be described edantic or dull, for here is a quotation: "Psycho-analysis already psyched almost everything worth psyching, and it went into old traditions and folklore it found so many lels with fantasy and day-dreaming that it took a kangaroo to the conclusion that *all* old stories and religious accounts merely dreams and fantasies on large scales—racial ensation dreams."

he Honorary Secretary of the Library Association states that publication of the *Subject Index to Periodicals, 1922*,[8] com- es 6,200 entries obtained from the examination of 300 odicals. To review a restricted list of selected references to e of the subjects published more than four years ago comprised in the scope of the terms "science" and "technology" ires the reviewer to put himself in the position of an irer in a library concerning some one of the subjects included he index. If the inquirer consults one of the periodicals rred to he will find further references made to his subject ing 1922. Moreover, he will, with a little more research, over other publications during the same period which relate is subject. There would, then, appear need for an explana- , placed upon the forefront of such an index, as to the is upon which the selection of such references has been le in order to induce a library to preserve the collection references as of permanent value, although made some e ago.

PATENTED RESEARCH.

IN an article under this title published a short time ago (March 12th, p. 479) reference was made to the action of Dr. George Dick and Dr. Gladys Dick in patenting the method they had elaborated for the recognition, prevention, and treatment of scarlet fever, and the wisdom of this course was called in question. They have now made a communication to the *Journal of the American Medical Association* for April 23rd, the last issue to reach this country, in which they explain the motive by which they were actuated. Their early researches were published in 1923 and 1924, and accounts of their results were given in this JOURNAL from time to time.

In the statement now published they say that it was suggested at about this time to them that a patent should be obtained in order to safeguard the quality of the materials sent out. At first they rejected the suggestion, but later on commercial firms began to distribute products undesirable on account of faulty methods of preparation, inaccurate standardization, or inadequate dosage. The action of these firms convinced them that some additional means of controlling the quality of the scarlet fever products ought to be found. After consultation with prominent members of the medical profession and with Government officials a patent was obtained. Its administration was placed in the hands of a committee composed of the director of the John McCormick Institute, where the research was done; two well known philanthropists who have made liberal donations to research, medical schools, and hospitals; the benefactor whose generosity was largely responsible for the development of scarlet fever antitoxin; the attorney who obtained the patent and who had consulted officers of the American Medical Association and had their approval before undertaking that work; a secretary; together with the two Drs. Dick, who would furnish technical advice as to the methods, standards, and dosage. "No member of the Scarlet Fever Committee," the statement continues, "receives any compensation for his services, with the exception of the secretary, who receives $25 a month." It is stated that during the first year and a half of its existence, the Scarlet Fever Committee secured the co-operation of four of the best American manufacturers, who agreed to distribute only those scarlet fever preparations which should meet the standards of the committee. It is stated further that when the application was made for the British patent (as reported in our columns on March 19th, 1927, p. 526) a licence was offered to one of the largest manufacturers in England, but that no answer was received. The preparations made by manufacturers licensed in America can now, it is stated, be obtained in England. With regard to the sale of the products "the Scarlet Fever Committee does not attempt to fix prices, believing that by not granting a monopoly, thus retaining the factor of competition, and wording the licence contracts so that with every reduction in price to the consumer the manufacturer reduces the sum paid the committee for testing his products, the lowest prices compatible with good quality and fair profit to the manufacturer will most quickly come into effect. This belief has been justified by the reductions in prices already made by licensed manufacturers." From the statement before us we learn that the committee maintains an organization for testing samples of every lot of each scarlet fever product manufactured by its licensees. Two health departments in the United States which made application received free licences. In addition, the committee has furnished without charge the materials and workers necessary to the control of a number of epidemics of scarlet fever in communities, schools, institutions, and hospitals. The committee also maintains research work directed towards the solution of technical difficulties and other problems connected with the control of scarlet fever.

We readily and frankly admit that, though the general principle involved raises considerations which are of serious and, it may even be, sinister importance, this statement is sufficient to show that, as we had hoped might prove to be the case, no charge against the investigators, Drs. George and Gladys Dick, of seeking to commercialize their method

for their own pecuniary benefit or that of any organization, can be sustained. They were in a difficult position, as others have been and will be, and no doubt took what they felt to be the best way out.

The *Journal of the American Medical Association*, in commenting on the statement by the Drs. Dick, writes:

Medical science and its discoveries for the relief of human ills should know no national boundaries. Nevertheless, the intricacies of modern commercial methods make necessary some means for protecting the discoverer and the public against those who would take undue advantage of both. The Insulin Committee of Toronto, the patents on thyroxin and on the scarlet fever preparations, have been attempts to find a way in the maze of commercial promotion and deceit. Perhaps none of these methods is satisfactory. Some organization—the American Medical Association, the British Medical Association, the Medical Research Council of Great Britain, or even the Chemical Foundation—should seek a means of giving the discoverer his due, throwing the products open to fair competition in manufacture, protecting the public, and prosecuting to the utmost those who undertake to go beyond the magnificent altruism of medical tradition for their personal gain.

That opinion in America on the advisability of patenting the application of results of research is not unanimous is shown by an editorial article in the *American Journal of Public Health* of last September, to which our attention has just been called. It states that the taking out of a patent by the Drs. Dick on the production of a scarlet fever toxin and antitoxin has led to a great deal of criticism.

No new bacteriological procedure was involved in their production. . . . Scarlet fever antitoxin was made in Vienna many years ago and used with success. . . . There does not appear to be anything strictly original in the method of growing the germ or the production of the serum, and one is indeed puzzled to understand how it was considered patentable. . . . It is well known that scarlet fever toxin and antitoxin are being produced by methods different from those put forward by the Dicks, and from cultures obtained from different sources, with results which are apparently equal in every respect to those obtained from material controlled by the Dicks, and the Scarlet Fever Committee, of which they are members. . . . There seems to be no reason for believing that preparations licensed by the Scarlet Fever Committee are or will be any better than those put out under the authority of the Public Health Service.

THE ROYAL AIR FORCE.

REPORT ON THE HEALTH OF THE FORCE IN 1925.

THE report on the health of the Royal Air Force for the year 1925 deals with a total strength of 33,028, of whom 23,838 were stationed in the United Kingdom, 3,632 in stations of the Mediterranean littoral, 3,590 in Iraq, and 1,950 in India. The personnel in the Mediterranean littoral includes 2,092 in Egypt, 692 in Malta or on aircraft carriers, and 593 in Palestine. The disease and injury incidence is admirably analysed in a series of four chapters, with appropriate tables in each.

The incidence of sickness and injury, excluding minor cases of less than forty-eight hours' duration, amounted to 447.2 per 1,000 of the total force, as compared with 463.6 in 1924 and 494.8 for the previous three-year period. The death rate was 4.2 per 1,000, compared with 4.5 in 1924. The actual number of deaths was 138, and of these only 36 were due to disease, while 102 were due to injuries. This marked excess of deaths from injury as compared with deaths from disease is characteristic of the Air Force and significant of the risks of flying. The total number of injuries in 1925 was 2,239, or 67.8 per 1,000 of strength. The report gives a full and interesting analysis of these: 61 per cent. occurred on duty, and, as in previous years, the majority, 48 per cent., were injuries of the lower limbs, chiefly sustained in athletics. The number of flying casualties on duty was 155, as compared with 169 in 1924. They were comparatively fewer in 1921, 1922, and 1923, when the numbers were 86, 102, and 112 respectively. The deaths from flying accidents were 55, but, taken as a percentage of the total flying casualties—namely, 35 per cent.—they compare favourably with all these years, the percentage being 42 in 1921, 49 in 1922, and 41 in 1923 and 1924. Eight of the deaths were caused by collisions. There were 33 injuries and 1 death from handling or in connexion with airscrews, 43 injuries were from starting other engines, and 400 with 18 deaths from motor accidents. Parachute descents caused 5 admissions for injury, 1 of which was fatal. There were also 4 cases of wounds in action when an aircraft was shot down in Iraq, and also in India; all proved fatal. There were 5 deaths from drowning whilst bathing.

There is little to note in connexion with the incidence of disease. Venereal diseases have fallen from 22.3 per 1,000 of strength in 1924 to 19.9 in the year under review. The highest disease incidence, chiefly from influenza, diseases of the upper air passages and of the digestive system, occurred amongst apprentices. A useful table indicates the case incidence according to age groups, the strength of each of which is shown. The age group under 18 shows an incidence of disease practically double that of other age groups, while the age group 24 to 25 shows the highest injury incidence.

In stations abroad Basrah proved the most unhealthy, as in previous years, with an admission rate of 922.4 per 1,000 of strength. Dysentery, malaria, and sandfly fever accounted for 60 per cent. of the admissions. The report notes that the prevailing type of dysentery in the stations abroad was protozoal in origin, thus emphasizing what has already been recorded regarding the prevalence of this type in Eastern countries. Two cases of primary infection with benign tertian type of malaria occurred in England at Eastchurch, neither of the patients having served abroad. It is stated that malaria is not uncommon amongst the civilian population of the district.

The final chapter of the report deals with miscellaneous subjects, such as the work of the Central Medical Board; the medical officers' school of instruction and research laboratory; the physical efficiency examination of officer and airman pilots, which takes place at the end of each year; the medical examination of recruits; hygiene and sanitation at home and on foreign stations; and a few other subjects, including transport of sick and wounded by air. On this last duty aircraft made 81 journeys in Iraq, carrying 176 cases, as compared with 81 cases in 1924, and flying 14,492 miles. It is only in Iraq that aircraft are employed as a routine procedure for this purpose. Several types are used, including specially constructed ambulance aeroplanes for sitting or stretcher cases and attendants; 126 of the 176 cases were carried in these.

The report as a whole maintains the high character of the annual reports of the medical department of the Royal Air Force, and contains statistics, such as incidence of disease and injury according to strength of each age group, not found in the reports of the health of the Army or Navy. It is also of interest to note that the success of the Air Force in the prevention of sandfly fever in Malta, in accordance with the methods recommended by the R.A.F. Sandfly Commission of 1922, continues; and that considerable activity is displayed in connexion with pathological work in Royal Air Force laboratories. Clinical laboratories were established in 1925 in the R.A.F. hospitals at Halton and Cranwell in England, and at Hinaidi, Basrah, Mosul, and Ludd abroad. The central laboratory was moved in January from Finchley to Halton as a separate unit, and designated the R.A.F. Pathological Laboratory, to act as a centre for the clinical laboratories.

PATHOLOGICAL RESEARCH UNDER THE METROPOLITAN ASYLUMS BOARD.

OPENING OF NEW LABORATORIES BY MINISTER OF HEALTH.

THE new research and pathological laboratories of the Metropolitan Asylums Board, situated at Park Hospital, Hither Green, were opened by the Minister of Health on May 9th. These laboratories have been built as part of a plan of reorganization of the research and pathological services upon which the Board embarked in 1924. It was then decided to transfer certain of the laboratory work hitherto carried on at Belmont, in Surrey, to laboratories attached to "acute hospitals," and in the first place to institute two group laboratories, one in the north and the other in the south of London, each to serve the needs of several hospitals by carrying out work requiring special technique and undertaking original research. A temporary building has been adapted at the North-Eastern Hospital to serve as the northern group laboratory, and the new laboratories at the Park Hospital will form the southern group laboratory and be the headquarters of the Board's director of research and pathological services. Routine bacteriological examinations will be carried out at each of the Board's hospitals, but such work as virulence tests, section cutting, blood culture, and the preparation of vaccines will be undertaken at the group laboratory, as well as investiga-

quiring animal inoculation. The laboratories are for research into the primary causation of the from which the inmates of the Board's institutions ering, and as the largest section of the Board's the provision for cases of infectious disease the ries have been built in association with a fever Arrangements have been made whereby volunrkers can be granted facilities for research in the ries.

aboratories, which are separate buildings in the of Park Hospital, comprise a main block for the ry proper, with a lecture room for medical students ig the hospital for instruction in fevers, and, at a stance, an animal house. On the ground floor of n building are a media room, opening from which ilizing and centrifuge rooms, and a cold and a hot The cold room, insulated with slab cork, has a mean ture of 32-37° F., and the hot room is kept at by means of a steam pipe. On the first floor are nd smaller laboratories, a section-cutting room, and graphic department. The animal house has pens for bbits and guinea-pigs, an experimental room with ial cages of galvanized iron, and a small inoculation a which experiments are done and autopsies on performed. In the equipment of the laboratories improvements have been introduced into the stand types of apparatus to secure ease of working, and ar instruments have been provided as far as possible ent eye fatigue. The total cost of the buildings, r with fittings and equipment, has been about).

he opening ceremony the chair was taken by Mr. Morris, J.P., chairman of the Board, and other rs and officials were on the platform, including H. Thomson, chief medical officer of the infectious ls service, Dr. J. E. McCartney, director of research thological services, and Dr. T. H. Woodfield, medical tendent of Park Hospital. The Chairman said that infectious diseases work of the Board, which was on in sixteen hospitals containing 8,800 beds, all f problems had to be faced. He gave as an illus- the recent rearrangement of the provision for s and for scarlet fever in view of the fact that the n type of scarlet fever seemed to be growing milder e common type of measles more virulent. The Board llowed the plan of the general hospitals in giving ty facilities as possible for the education of students various institutions. It had also devoted itself for years past to the subject of prevention. In 1909 it the work of serum production at Belmont, and in ppointed a research pathologist to inquire into the ion, infectivity, prevention, and treatment of zymotic , and to keep in touch with the medical superintenof the various infectious diseases hospitals with a o elucidating the primary factors in the causation diseases from which the patients in the hospitals suffering. This research pathologist was provided laboratory at first at the Lister Institute and later National Institute of Medical Research. In 1921 oard, after consultation with the Medical Research il, set up a scientific advisory committee, of which . H. Thomson was chairman, to exercise general ision over the research work carried on by the patho- and over the diphtheria antitoxin and bacterio- l laboratories. It was following upon a report from ommittee that the present developments had ensued. pressed thanks to Sir George Newman and Sir George man, of the Ministry of Health, and Sir Walter ier, of the Medical Research Council, for much ble advice and assistance, and said that the Board nxious that the new laboratory should be used, not for ie work, but for fundamental discovery.

NEVILLE CHAMBERLAIN said that vast as was the utional provision made by the Metropolitan Asylums l it could not be said to be too large. Last year ndon, apart from tuberculosis, 33,000 cases of in- us disease were notified. The Board was known ghout the country as a model of administration, but naintenance of these hospitals was a very expensive matter, and meant a substantial addition to the burden of the rates which was bearing so heavily upon the urban dweller. Mr. Chamberlain drew an allegory from his own experience as a manufacturer before he went into politics. One of the problems which he had constantly to face in his industry arose out of the presence of flaws in the material which were not discoverable until a considerable amount of money and labour had been spent in production. To find a means of discovering flaws at the earliest stage and of eradicating them was the continual concern of the manufacturer. Much the same thing applied in the infinitely more complex mechanism of human life. About 5 per cent. of the children born in London died from one of the infectious diseases before reaching adult age, while among those who survived there was an unknown proportion of crippling and disablement. If that wastage could be prevented it would mean—dismissing for the moment higher considerations and sentiments—a substantial decrease in the responsibilities of public bodies, and incidentally in the precepts which they were compelled to make upon the ratepayers. He thought it somewhat extraordinary that research upon the cause of infectious diseases should have been so late in arriving. Years ago, as a member of a public body, it was his duty from time to time to inspect an infectious diseases hospital, and he remembered that on the occasion of his first visit he asked the very clever and bright young gentleman who accompanied him to tell him what was the cause of scarlet fever. "Judge of my consternation when I found that I had bowled him out first ball." Even now it was not certain that the cause of scarlet fever had been ascertained. Some medical men thought that the villain of the piece had been discovered, others were of opinion that the wrong party was suspected, and there was still much to be done in the way of research. The average stay in hospital of a scarlet fever patient was eight weeks. If research could diminish the period by one week it would mean no small relief in a work of such dimensions as that of the Board. As a layman he was compelled to speak in non-technical terms with regard to the recent work on the building up of the defensive mechanism against scarlet fever; it seemed to him that an army of "anti-reds" was being trained to assist the regular forces of the patient's constitution. In diphtheria the guilty party had been arrested, tried, and convicted, and there a material advance had been made in immunity and in checking and controlling outbreaks of the disease. The case mortality from diphtheria in London at the beginning of the century was about 15 per cent., and to-day it was down to below 4 per cent. He would not say that that was all due to these discoveries, but nobody could doubt that they had played a considerable part in this reduction. To his mind the results achieved in these two diseases—scarlet fever and diphtheria—were sufficiently encouraging to enable it to be said that the money spent upon the provision of facilities for research was a good investment. The laboratories [illegible] er in size or ornament; they were but with the eye of imagination [illegible] them in the light of the great achievements of which they might be the home. Here might be won some of those victories which, though they did not ring round the world like Waterloo, nevertheless had their deep and permanent effect upon the happiness and prosperity of the human race. As Minister responsible for the department whose chief object was to reduce the necessity for having such a Minister at all, he commended the work, and congratulated the Board on the vision and imagination which had led it to plan this enterprise.

The thanks of the Board to Mr. Chamberlain were conveyed by the Rev. Canon SPRANKLING, chairman of the Infectious Hospitals Committee, and Sir D'ARCY POWER, a member of the Board. Among others present at the ceremony were: Sir George Buchanan, Sir F. W. Andrewes, Sir Walter Fletcher, Lieut.-General Sir M. H. G. Fell, Professors C. J. Martin, A. E. Boycott, and L. S. Dudgeon, Dr. Andrew Balfour, Dr. T. Carnwath, Dr. Morley Wenyon, Dr. Foord Caiger, and the mayors, medical officers of health, and town clerks of Lewisham, Camberwell, and other metropolitan boroughs.

SIXTH BRITISH CONGRESS OF OBSTETRICS AND GYNAECOLOGY.

(*Continued from p. 844.*)

The Cancer Problem in Gynaecology.

The second day of the congress was devoted to various papers and short discussions. Professor ARCHIBALD DONALD presided over the morning session, which was opened by Dr. W. P. GRAVES of Baltimore, who read a paper on the cancer problem in gynaecology.

Dr. Graves said that the object of his paper was to promote a more intelligent prophylaxis in treatment of those forms of cancer and pre-cancerous states related to gynaecology. In the combat against any given disease three factors had to be dealt with—namely, the primary cause, the exciting cause, and the cure. The primary cause of cancer was as yet unknown, but in many cases the exciting cause was certainly the prolonged irritation caused by discharges from neglected lesions or trauma. Cure was only obtained by surgery or irradiation, and for this early diagnosis was essential. Dr. Graves referred to the preponderance of cases of carcinoma of the cervix following injuries due to pregnancy, and to the frequency of previous uterine or cervical lesions in those cases occurring in nulliparous women. When no previous pathological factor was present he could only postulate an hereditary predisposition. As regards prophylaxis he had found that out of 5,000 cases where cervical lacerations had been repaired, only two had developed carcinoma of the cervix; he advocated early repair of cervical lacerations in all cases, since carcinoma, as shown by Leitch, might develop long after the source of irritation had ceased. Dr. Graves described several cases of carcinoma of the corpus uteri where the lining epitholium of the uterine cavity must have been subjected to the influence of a pent-up irritating secretion for a long period prior to the onset of carcinoma. This, he maintained, was the causative factor in the onset of carcinoma. In the same way he thought that the irritation caused by the contents of an ovarian cyst might convert an originally benign type into a malignant one. Similarly a discharge from the upper genital tract might give rise to a pre-cancerous and later to a cancerous condition of the vulva. He pleaded for early surgical treatment of all gynaecological conditions which might be the precursors of carcinoma.

Professor BLAIR BELL (Liverpool) endorsed Dr. Graves's views, and advocated that all women at and after the menopause should undergo periodic examination with a view to early detection of carcinoma. Sir EWEN J. MACLEAN (Cardiff) was not optimistic about the surgical possibilities in the cure of cancer. Of all the patients he had operated upon for carcinoma of the cervix only one was alive ten years subsequently. Dr. T. W. EDEN (London) agreed that all energies should be concentrated on diffusing knowledge that would bring cases of malignant disease to the surgeon at an early stage. Professor LOWRY (Belfast) referred to the importance of educating the general practitioner in this respect. Dr. ALLAN FOTHERGILL (Edinburgh) thought that a routine examination such as was suggested by Professor Blair Bell would result in widespread cancerphobia.

Sudden Death Caused by Manipulation of the Pregnant Uterus.

Sir BERNARD SPILSBURY (London) read a paper on sudden death due to manipulation of the uterus during pregnancy. He stated that in these cases death had occurred in circumstances pointing to an attempt to procure abortion. In the majority death had followed the injection of fluid into the uterus, partly separating the membranes. In two cases the introduction of an instrument into the cervical canal had proved immediately fatal, and in a third case the instrument had been passed into the body of the uterus. Death was caused in one case by the removal of a rubber tube which had been inserted into the cervical canal on the previous day. In not one case was serious disease found to account for death, and in the majority no disease could be found even on microscopical examination of the organs. The conditions leadi to these fatalities were: (1) the emotional state of t woman at the time of the attempt; (2) shock caused the manipulation; this appeared to be a reflex vasomot paralysis, producing a rapid fall in blood pressure.

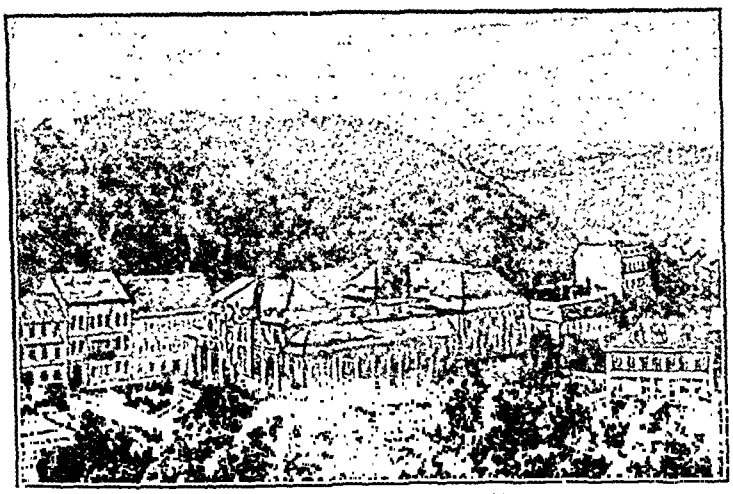
Dr. A. DONALD (Manchester) commented on the su prisingly slight incidents which sometimes caused deatl Professor W. FLETCHER SHAW (Manchester) thoug careful consideration was necessary before accepting Si Bernard Spilsbury's views. The cause of death had n been proved, and an important factor—the possible after effects of drug taking—had been omitted. Professo R. W. JOHNSTONE (Edinburgh) suggested air embolism as possible cause of death in some cases. Professor BECKWIT WHITEHOUSE (Birmingham) said that no comparison coul be made between these cases and those of legitimat practice, in which the extreme emotional state was absent this was an important factor in sudden death. Si BERNARD SPILSBURY, in reply, said he had never seen case of air embolism following abortion, and doubted very much whether it occurred. He also emphasized the necessity of associating the medical findings with the criminal history and admissions. He compared these deaths with those which occasionally occurred on passage of a catheter. The possibility of degenerative lesions in the organs due to the taking of drugs could not be excluded.

The Use of Pituitary Extract and Ergot in Labour.

At the opening of the afternoon session, with Professor R. J. JOHNSTONE (Belfast) in the chair, Dr. ALECK BOURNE (London) read a joint paper, prepared by himself and Dr. J. H. BURN (London), on the dosage and action of pituitary extract and of the ergot alkaloids on the uterus in labour, with a note on the action of adrenaline. The direct method of measuring and recording intrauterine pressure by means of a water-filled bag connected with a mercurial manometer and writing point on moving paper had been employed to estimate the action and dosage of pituitary extracts and the ergot alkaloids at Queen Charlotte's Hospital. The paper, which was illustrated by lantern slides of graphs and tracings, showed that a dose of two units of pituitary extract was safe and efficient during the later stages of labour. While the strength of the extract made by different manufacturers varied at present, it would be compulsory after August, 1927, for the containing ampoule to show the number of units. Of the three alkaloids of ergot, it was found that tyramine had no effect on the uterine musculature, while histamine produced a small but rapidly induced increase in the frequency and force of uterine contractions when given in large doses. The effect was short-lived, and left the uterus in a condition of atony. Ergotamine caused a slow but prolonged state of uterine tonic contraction. Adrenaline given intravenously was found to induce a short period of complete uterine inhibition.

Deep X-Ray Treatment in Gynaecology.

Dr. L. CASSIDY (Dublin), in a paper on deep x-ray treatment of non-malignant gynaecological conditions, said that small doses of x rays produced a marked increase in cellular activity. From the practical standpoint two factors entered into consideration: first, the changes in cells and organs subjected to x rays, and secondly, the generalized effect upon the blood and nervous system. For hypomenorrhoea he advocated small stimulating doses to the ovaries. In a few of these cases radiation of the hypophysis had given very satisfactory results. In cases of complete amenorrhoea due to endocrine deficiency menstruation had returned in four cases after treatment by x-ray applications to the ovaries or hypophysis. In the same way, out of 20 patients with dysmenorrhoea and scanty menstruation, 10 had been cured and 4 much improved by radiation of the ovaries or hypophysis or both. For the polymenorrhoea of puberty and the menopause he recommended splenic radiation, and added that in menopausal bleeding unrelieved by splenic radiation cure could easily be effected by full doses applied to the ovaries. He also advocated small doses of x rays for abdominal and pelvic tuberculosis and for parametritis.



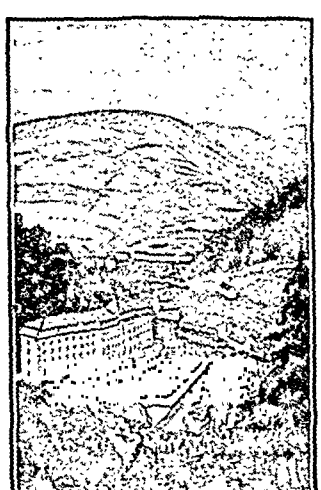
(To be concluded.)

THE SPAS OF CZECHOSLOVAKIA.

A MEDICAL TOUR OF PRAGUE AND THE HEALTH RESORTS.

JUST over a year ago the International Society of Medical Hydrology held its annual meeting in Czechoslovakia, in response to invitations from the Government and the spa municipalities of the new Republic. The members, numbering about 80, of whom a third were British, spent a week in visiting Prague and some of the chief watering-places of Bohemia and Slovakia.

This spring another party of British medical men, with a leavening of writers, made a longer tour of that country as the guests of the Society of Czechoslovak Spas, travelling day by day through the western spas to Prague, and thence eastwards to the Tatra Mountains on the Slovak-Polish frontier. In the course of a crowded fortnight they passed three nights in the capital, and examined, all too perfunctorily, a dozen health resorts. At every halting-place they were met by the leaders of the local profession and the civic authorities, whose kindness knew no bounds, and special facilities for travelling within the Republic were granted by the Government through the good offices of the Minister of Public Health and Physical Education, two of whose staff accompanied the party. Some acknowledgement of these and other courtesies will be made presently, and all that need be said now is that the organization of the tour, from beginning to end, was beyond praise.

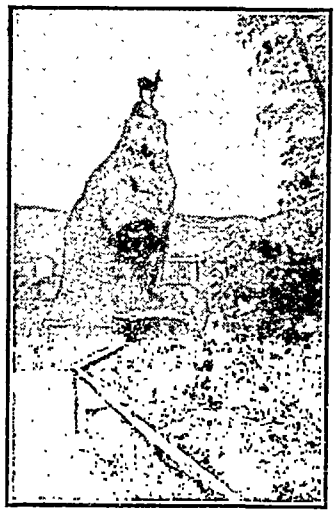


Teplitz-Schonau: Steinbad Bathing Establishment.

Czechoslovakia has been termed the land of spas, and apart from its natural charm and the architectural beauty of its capital the country has much to interest medical visitors. Nearly every branch of balneological practice can be studied on the spot at one or other of its watering-places; sanatoriums for the treatment of tuberculosis and other diseases abound in the Tatra Mountains; and Prague, with its universities, hospitals, clinics, and medical societies, is a great centre of professional teaching and scientific research. In this and later articles we shall give a brief account of the places seen, mainly from the medical point of view. A note on Czechoslovak Medicine appeared in the BRITISH MEDICAL JOURNAL of February 26th last (p. 396).

Of the many and varied spas scattered throughout the plains and highlands of Czechoslovakia a large part are municipal undertakings; others, such as Tatranska Lomnica, Strbské Pleso, and Jáchymov, are State-owned; and a few, like Pistany, are leased to private enterprise. Their names are now written in Czech, a language far too difficult for most foreigners, and it is not easy at first to recognize Carlsbad, Marienbad, Franzensbad, St. Joachimstal, and Teplitz-Schönau, under their new official designations of Karlovy Vary, Mariánské Lázně, Frantiskovy Lazne, Jáchymov, and Teplice-Sanov. These five mineral water stations lie in the north-west corner of Bohemia, and the first three at any rate, although renamed by order of the Czech Government, are still predominantly German. On the other hand, Poděbrady, within an hour's railway journey of Prague, is and always has been Czech through and through, while the "atmosphere" of Pistany and the health resorts of the High Tatras is almost as Slovak as their language. The first draft of the itinerary included a trip to the Moravian spa, Luhacovice (formerly Luhatschowitz), near the Hungarian frontier, but this was omitted out of consideration for the already hard-driven travellers; otherwise everything went very much according to plan. Most of the places were as yet scarcely out of winter clothes, so that their attractions in the high season had to be taken on trust.

The expedition left London on the morning of Thursday, April 14th, and returned on the night of Sunday, May 1st. Its route lay through Harwich, Flushing, Hanover, Leipzig, and Dresden. A railway accident near the Dutch frontier caused twelve hours' delay on the outward journey, and Good Friday was spent in travelling through Holland and Germany. At the Czech frontier town of Podmokly (Bodenbach) the visitors were met by Dr. Karel Driml, on behalf of the Minister of Health. Thereafter a special coach carried them on all their travels over the railway system of the Republic, with Dr. Driml and Mr. Zlaml (in charge of transport and hotel arrangements) as their guides and constant companions.

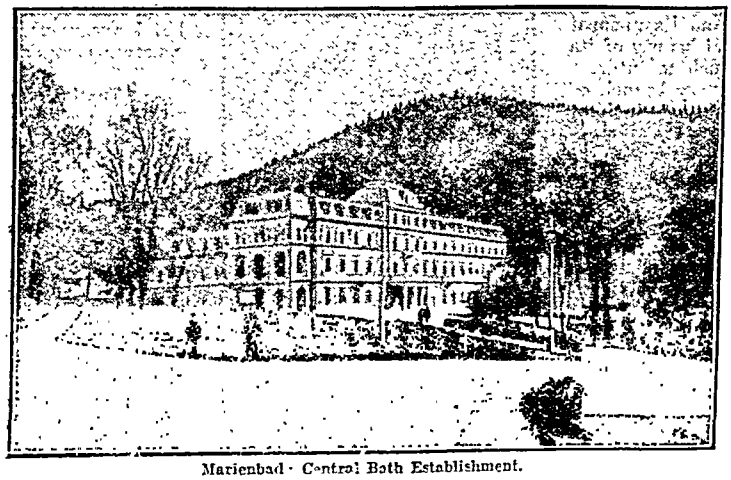


Jáchymov: Radium Palace Hotel and Baths.

Teplice-Sanov and Jáchymov.

These two spas, the first on the programme, have little in common beyond the radio-activity of their waters. Teplitz-Schönau, to give it the more familiar German name, is the oldest health resort in Czechoslovakia, with a history going back to Roman times and beyond. Its hot alkaline springs were very fashionable 120 years ago, and many illustrious names may be found in the archives. The well ordered bathing establishments are used for the most part by patients with chronic rheumatic and gouty disorders. The town is pleasantly placed, about 730 feet above sea level, in a wide valley sheltered by hills. From May to September is the best time for a visit, though the baths are said to be open all the year round; the Kurgarten must be delightful when the leaves are on the trees. After looking over the main bath-house and theatre the visitors were entertained to lunch by Count Clary, who welcomed them in perfect English in the name of the municipality and of his family, which has been closely linked with Teplitz-Schönau for 300 years.

Jáchymov (formerly St. Joachimstal) was reached in driving snow after a journey by train and car. Parts of this little winding one-street town are old, but the spa



is quite modern. The mines are historically interesting for two reasons: "dollar" and "thaler" (Joachimstaler) owe their name to the silver extracted and coined there early in the sixteenth century, and in 1898 radium was first obtained by Pierre and Madame Curie from the waste of Joachimstal uranium ore. The discovery in 1905 of a briskly radio-active spring (600 mache units to the litre), in one of the uranium mines, led to the building of a bath establishment, and later of a large hotel and an irradiation pavilion—all now owned by the State. Jáchymov, though not at any great height, must be reckoned a hill station, with the Ore Mountains rising picturesquely above it to the north. Its doctors have profound faith in the healing virtues of the water, whether applied outwardly or drunk or inhaled; and even a single hot radio-active bath, as any visitor can prove for himself, is distinctly refreshing. The Radium Palace Hotel, a fine building on a fine site, is immediately opposite the baths.

Carlsbad: the Hirschensprung.

Carlsbad, Franzensbad, Marienbad.

A short motor run from Jáchymov on Easter Sunday took the travellers to Karlovy Vary (Carlsbad), the largest and most important watering-place in the Republic, best seen as a whole from the high ground near the railway station. Carlsbad, at an altitude of some 1,200 feet, is a considerable town straddling the Tepla gorge and enclosed on each side of the river by parks and wooded hills. It is a palatial spa, so well known that there is really nothing new to be said about it. The mineral springs and bath establishments lie along the course of the river, into which the waste water runs, disclosing its presence by clouds of steam. Some of the springs are hotter and therefore less gaseous than others, but the chemical constitution of them all is much the same. The chief salts are the sulphate, bicarbonate, and chloride of sodium, and of the various springs the hottest and the most famous is the Sprudel, gushing up in the pump room, at a temperature above 160° F., to a height of 20 feet. Each water drinker walks off with his ration and lets it cool before he sips it and goes for his morning promenade. Nevertheless, as Ernest Hart wrote in these columns forty years ago, the problem which remains unsolved is what part the Carlsbad water really plays in the Carlsbad cure. Of the various bathing establishments that styled No. 1 is superbly appointed and has a large hall fitted with Zander apparatus. Luxury is still the keynote of Carlsbad and prices run high, but besides the thirty-five hotels for the rich there are innumerable boarding houses for poorer folk with livers just as large. The party from England were entertained at a banquet presided over by Dr. Wagner, and next morning Dr. Paul Meyer and Dr. Edgar Ganz showed them round the baths and other attractions of the place.

Marienbad: Central Bath Establishment.

Frantiskovy Lazne, or Franzensbad, is a garden spa 300 ft. higher than Carlsbad, charmingly situated among open moorlands. The bathing establishments, hotels, and pensions are modern and well managed. There are eighteen different cold mineral springs, one of them extremely rich in sodium sulphate, another very pleasant as an ordinary sparkling table water, and a third much used in anaemia for its saline chalybeate properties. A very large proportion of the patients who go to Franzensbad are *women*. *The principal* outward treatments are by peat baths (the material being found locally in great abundance) and by natural carbonic acid baths. Therapeutic indications and methods were described by members of the local profession during the tour of the baths, and Professor Zörkendörfer gave an instructive account of the chemical and physical properties of the waters. After a luncheon party in the Kursaal the visitors were driven by car to Eger, and thence took train to Marienbad, carrying with them a very agreeable memory of Franzensbad and its inhabitants.

Franzensbad: West End Park.

Marienbad (Márianské Lázně), 2,000 feet above sea level, near the Saxon and Bavarian frontiers, lies in a broad valley enclosed by pine forests. Here in a beautiful setting the wealthy and full-blooded patient may deplete himself under skilled advice, the action of the cold sulphated alkaline waters being smoothed by every amenity that money can buy. The baths of this famous spa are indeed *magnificent*. *At the local Balneological Institute the* virtues of the springs were expounded from the clinical aspect by Dr. Max Porges, and from the chemical and physiological by Professor Zörkendörfer, who had travelled with the party from Franzensbad. Later in the evening a dinner, given by the municipality and the baths administration, was presided over by the Burgomaster. Next morning, after an inspection of the wells and baths, some of the party walked to the factory where the water from the Ferdinand spring is evaporated and the salt bottled for export. The general idea gained during a too brief stay was that those who can afford its prices, and whose tastes and figures turn outwardly so to speak, will long continue to regard Marienbad as the ideal inland watering-place on the continent of Europe.

Subsequent notes will deal shortly with some of the medical institutions of Prague, and with Poděbrady, Pistany, Trencsénteplicz, and the High Tatra health resorts.

British Medical Journal.

SATURDAY, MAY 14TH, 1927.

THE CONSTITUTIONAL FACTOR IN DISEASE.

DURING this century the word "constitution," previously employed more by the lay public than in a definite professional sense, has by a swing of the pendulum come back into medical parlance, and this in two different connexions. Epidemiologically Hamer, Greenwood, and Crookshank have revived interest in Sydenham's "epidemic constitutions" of diseases, a further development of Hippocrates's views, and a rather mysterious conception of some influence—climatic or telluric—independent of the resistance of the host and of variations in the infecting agent. This, according to Professor Major Greenwood, meant that upon distinct epidemic diseases there was superimposed a common external form or group of allied forms. The other use of the word "constitution" is nearer that generally understood—namely, as applied to the individual. This was much in vogue before the advent of bacteriology, and was embodied in the teaching of John Hunter, Thomas Addison, Thomas Laycock, and Jonathan Hutchinson. But, like the interest in the closely allied subject of the diatheses, that in constitution, or the bodily make-up of the individual, waned before the etiological promise of bacteriology, which diverted attention from the internal and hereditary factors to the external causes of disease. This phase, however, lasted for a time only; Kraus at his anthropological clinic in the Charité Hospital in Berlin applied the methods of anthropology to the investigation of human constitution, which Knud Faber[1] defines as "the nature of the body, including under this all inherent properties, such as the anatomical structure of the body, its morphological composition, as well as the functioning properties of the separate organs and cells." Constitution therefore includes hereditary variations from the average both in structure and in function, and of the latter Sir Archibald Garrod's inborn errors of metabolism are a good example; these may obviously be advantageous, harmless and of no importance, or with pathological effect. Although Emerson confirmed the proverbial phrase that "every definition is dangerous," clear thinking depends on an understanding and accurate use of terms, and it may be well to have a distinct notion of the relation of "diathesis" to constitution. Sir Jonathan Hutchinson regarded diathesis as "any bodily condition or prolonged peculiarity of health giving proclivity to definite forms of disease," or, more briefly, as "a persisting morbid proclivity." If this interpretation be adopted, diathesis may be considered to be much the same as a morbid constitution. George Draper has been working on the same lines as Kraus for some six years at the Presbyterian Hospital, New York, and regards constitution as "the aggregate of hereditary characters influenced more or less by environment, which determines the individual's reaction, successful or unsuccessful, to the stress of environment." By means of anthropometric methods previously employed to differentiate the races of mankind he has separated out distinct types for diseases, such as peptic ulcer, gall-bladder affections, high blood pressure and chronic nephritis, pe anaemia, asthma, tuberculosis, and acromegaly

Dr. Arthur Hurst, like Sir Samuel Wil predecessor at Guy's Hospital, is a faithful in the steps of Thomas Addison, whose res he has pursued on present-day lines. He d in Paris in October, 1922, two lectures on diatheses, and recently at Belfast gave a expanded account of "The constitutional fa disease" in the address the publication of w completed this week. He passes in review th gastric diatheses, the constitutional basis of A anaemia, commonly called pernicious, and s combined degeneration of the spinal cord, o cystitis, diabetes, nephritis, phosphaturia an phatic calculi, high and low blood pressure, asthma, epilepsy, and migraine. In connexi the frequently described conditions of the hy stomach and the dropped stomach he insis these x-ray appearances are merely anatomica tions from the average length of the healthy which may normally—that is to say, withc ducing symptoms—oscillate between 18 and Dr. Hurst deals mainly with functional consti phenomena rather than with structural va and shows how they favour the incidence of An example is afforded by what he calls the sthenic gastric diathesis, the subjects of which a to suffer from a duodenal ulcer; whereas the 4 of normal persons with constitutional achylia are, from the absence of the antiseptic barrier by the healthy stomach, disposed to infection teria contained in food and drink, and so to Ad anaemia and subacute combined degeneration spinal cord. In speaking of the hereditary f diabetes mellitus he argues that the prolong life and health in adult diabetics by insulin wi in a great increase in their progeny and so to incidence of the disease. He maintains also constitutional inherited liability of the isl Langerhans to undergo degeneration is as with a tendency to excessive stature in childh obesity in adult life. Martin H. Fischer[2] of Ci has argued that nephritis and its results are an increased production or accumulation of the kidney, and Dr. A. A. Osman has sho individuals with highly acid urine, which may ably be regarded as depending upon the consti and inherited variations in the complicated bioc processes responsible for the reaction of th are specially prone to suffer from acute n Conversely, some persons have a const tendency to pass alkaline urine, which is exa by mental strain and excitement; this c naturally favours the formation of phosphatic Though it is generally recognized that hig pressure is hereditary, yet it is commonly that there is some toxic factor behind it; Dr. contention, supporting the conclusions of Dra others, that there is a constitutional liability therefore attractive. Similarly the opposite hypopiesia is regarded as a constitutional c or diathesis and as merely an extreme variati the average. Asthma, epilepsy, and migraine present considerable resemblances, are all as depending on a constitutional and often i irritable focus in the brain; it has sometim stated that they are interchangeable in gen and members of the same family, but Dr does not accept that; his conclusion is th

[1] Faber, K.: *Nosography in Modern Internal Medicine*, p. 198, 1923, New York.

[2] Fischer, M. H.: *Oedema and Nephritis*, 1921.

several constitutional bases, though somewhat alike, are specific.

Obviously the practical importance of recognizing the constitutional factor in disease is that it will encourage the physician to antagonize the tendency, and so to carry out the principle of preventive medicine. On the importance of these prophylactic measures and on their nature Dr. Hurst is emphatic and clear. Thus the brothers, sisters, and children of patients with Addisonian anaemia, subacute combined degeneration of the spinal cord, and William Hunter's glossitis should be given test meals, and, if found to have achlorhydria, should, like all those with this deficiency, be given a drachm or more of dilute hydrochloric acid fasting three times a day for the rest of their lives; it may be well to add that if combined with sweetened orangeade or syrup of grenadine the beverage is quite palatable. A patient who, as shown by a blood count and Hijmans van den Bergh's test, has apparently recovered, should however well he may feel, nevertheless continue to take the acid, as the constitutional predisposition is there, and a relapse, due to fresh infection, may occur. Another clear indication is the correction of excessive acidity of the urine, especially during scarlet fever, by potassium citrate and sodium bicarbonate, a plan which in practice almost entirely prevented the occurrence of albuminuria and nephritis among 431 cases of scarlet fever. Of the treatment of asthma Dr. Hurst can unfortunately speak with great authority; of this, as of migraine and epilepsy, he epigrammatically remarks that "the only cure is not to have it"; there is not any drug, such as luminal in epilepsy and migraine, which has a favourable influence on the constitutional factor in asthma. This address, like all Dr. Hurst's contributions, is noteworthy for its power of stimulating thought, its logical acumen, and practical application.

SYNTHETIC DRUGS.

THE introduction of synthetic drugs has been the outstanding feature of pharmacology and therapeutics during the present century. The process started in the second half of last century and has gone on with ever-increasing rapidity, reaching its full development during the last two decades. Probably few, even of those who give special attention to the subject, are aware of the enormous number of synthetic drugs on the market; some idea may be gathered from the fact that the index to the new edition of Fränkel's well known book on drug synthesis[1] contains the names of some 7,000 chemical substances. It is also interesting to note that this new edition is not larger than the last, because the author has been able to delete a great deal of matter which has come to possess historical interest only; that is to say, of the drugs enumerated in the last edition, which was published in 1921, a large number have ceased to be of any practical importance This is partly due to the fact that advancing knowledge has led with fair regularity to the abandonment of hypotheses that were popular for a time. The search for new synthetic drugs is now systematically conducted on a large scale, and on a well understood plan, in big drug factories. Long series of chemical compounds are prepared and their pharmacological properties systematically tested. Only a small proportion of these prove to have any therapeutic value, and only a few even of these become established in the favour of the profession. Work of this kind is done chiefly by German and Swiss chemical firms, who have organized the search for new drugs on a scale unknown elsewhere. Consequently, the majority of new synthetic drugs come from these countries. It is obvious that if organic chemists and pharmacologists, working together as a team, are backed by the facilities and resources of great factories they must have opportunities completely beyond those of any ordinary university department. While it must be admitted that this commercialized research has undoubtedly done great service in producing valuable drugs, yet it has created certain special problems for the medical profession. The nature of these problems may be illustrated by one or two important classes of drugs; for example, Fränkel has had to devote thirteen pages to the description of derivatives of barbituric acid. Some hundreds of compounds are mentioned and references are given to about 140 patents. About forty compounds of this class of hypnotics have been advertised to the medical profession, among the best known of which are veronal, luminal, and dial. Another instance is afforded by the organic arsenicals. Fränkel's account of them occupies fifty pages; some hundreds of compounds are mentioned and references are given to 300 patents. In both these instances the organic chemists have produced a great many compounds, most of them protected by patent rights, and each series contains a large number of closely related chemical substances possessing very similar pharmacological actions.

Only a minority of these compounds are introduced to the medical profession, but even so the number of new proprietary remedies advertised is embarrassingly great; the reason for this state of affairs is obvious, for the manufacturing firms naturally wish to cover the cost of expensive research departments. The number of new synthetic drugs which represent striking advances in therapeutics is small, and consequently any compound presenting properties sufficiently novel to make it worth while to patent it, or showing any promise of being a slight improvement on existing drugs, has an excellent chance of being introduced to the medical profession. Usually manufacturers are able to back up their recommendations by reports of successful trials of the new drug in some hospital—a phenomenon which raises other considerations on which we do not now propose to enter.

Unfortunately the process is one-sided, for, on the one hand, any new proprietary drug has powerful advocates in those interested in its success, while, on the other, there is no mechanism for giving the medical profession a completely unbiased judgement on its merits. There appears, indeed, to be a danger that the organic chemists may hinder the progress of therapeutics by a very excess of zeal, for if the clinician has only the choice of a few drugs to produce a given therapeutic effect, it is possible for him to make a careful comparison of their efficiency, but if he is confronted with dozens of new compounds, all claiming exceptional merit, he will probably regard the task of adjudication as hopeless and will stick to the drugs possessing old-established reputations.

Another question of general interest is the increasing therapeutic importance of compounds protected by patents. Already synthetic drugs have replaced natural drugs to a large extent, and this process is certain to continue; moreover, the majority of new synthetic drugs owe their existence to what we have

[1] Von Dr. Sigmund Fränkel. Sechste J. Springer. 1927. (Sup. roy. 8vo,

termed commercialized research, and it seems probable that this will become still more common in the future. It seems likely, therefore, that most new synthetic drugs will be covered by patent rights. That this process is going on rapidly is evidenced by the fact that half the references Fränkel makes are to patent specifications. This increasing invasion of therapeutics by patented proprietary remedies is bound to raise special problems in the future. For example, in the past it has been possible for official publications such as the *British Pharmacopoeia* to ignore patented drugs, but it seems doubtful if this will be as easy in the future.

THE PHARMACOLOGICAL LABORATORIES OF THE PHARMACEUTICAL SOCIETY.

THE laboratories established by the Pharmaceutical Society to fulfil the conditions regarding the control of therapeutic substances the purity and potency of which cannot be adequately tested by chemical means, as laid down by the Therapeutic Substances Act, 1925, were formally opened in June last, but their organization had been in progress since January. The first annual report, which has now been issued, states that the work done has consisted, on the one hand, of the testing of various therapeutic substances sent by manufacturing firms, and, on the other, of research work, which in the main has been directed to the establishment of more accurate conditions for carrying out such testing. The substances the laboratories at first undertook to test were preparations of digitalis, strophanthus, squill, and ergot, and pituitary extract. Of seventeen samples of digitalis received, three were of leaf and fourteen of tincture; three were rejected—one because it was weak, and two because they were too strong. The remaining fourteen conformed to the requirements of the Conference of the League of Nations in September, 1925. That Conference had recommended the use of ouabain as a standard for strophanthus, but it was found necessary to determine a standard applicable to the tincture obtainable in Great Britain; this is that an average tincture should be equivalent to a solution containing 0.35 per cent. of ouabain. The investigation of squill had not at the time of the report yielded a definite result, but the use of scillaren—a crystalline glucoside obtained from squill by Stoll—will probably afford a satisfactory standard. Both these inquiries are being carried on in conjunction with Dr. J. W. Trevan. As the liquid extract of ergot of the *British Pharmacopoeia* does not contain the specific alkaloid of ergot the laboratories were under an obligation to determine the actual therapeutic value of the different physiologically active substances present in the drug. This work was carried out at Queen Charlotte's Hospital in conjunction with Mr. A. W. Bourne, F.R.C.S., and is approaching a successful conclusion. Clark's method of assaying ergot, which for the first time provided a means of determining the percentage of specific alkaloid in the crude drug, has been tested by Miss J. M. Ellis, Ph.C. (Redwood Scholar), who has assayed nine samples of crude ergot from different sources. It was found that there are wide variations in the content of specific alkaloid, and so soon as the pharmacopoeial preparations are altered it will be essential for manufacturers to arrange for the crude drug to be assayed before they buy it. Several investigations are being carried out on pituitary extract; one on the proper dosage in labour, along with Mr. A. W. Bourne, and another into the antidiuretic effect of different samples, undertaken at the request of the Health Committee of the League of Nations; a third on the effect of the extract in certain metabolic conditions has been begun. The original list has been increased and samples of adrenaline, ovarian extract, and parathyroid extract have been tested, and determinations of the toxicity of sodium tetra-iodophenolphthalein have been made. A vitamin-testing department is being formed under the direction of Dr. Katherine Coward, which will shortly be ready to receive samples. The address of the laboratories is 17, Bloomsbury Square, London, W.C.1.

A STRANGE SICKNESS.

ON July 11th of last year the medical officer of health for Poplar received a message from a local doctor to the effect that several of his patients were stricken with diarrhoea and vomiting. Zymotic diarrhoea being notifiable in Poplar from June to September, further intimations speedily followed from other practitioners in the area till the total number of cases reported rose to over a hundred; most were women and children. The usual duration of illness was twenty-four hours. The temperature ranged between 100° and 104° F. The diarrhoea was constant and severe. Labial herpes frequently ensued. Patients were left collapsed and weak, and three died. The morbid anatomy of the fatal cases showed no striking features. The small intestine was normal, the colon possibly a little congested. The bacteria isolated were of the colon type. The faeces of the living had various aspects, some resembling mild dysentery. In two cases Morgan's bacillus was found. The blood serum, tested for agglutination with the Salmonella and Flexner groups and the Sonne type, was completely negative. Ice-cream was blamed, but, on investigation by Dr. G. C. Hancock of the Ministry of Health, exonerated. No other food could be proved culpable. Gastric influenza and irritant poisoning of chemical origin were considered and set aside. The incidence was confined to a triangular area near Leven Road, and was heaviest on Leven Road itself, where scarcely a house escaped. The water supply, as a vehicle of infection, came under suspicion. A preliminary examination of the water from the local service was made by Dr. Scott of the Ministry, and it was examined later, in detail, by Sir A. C. Houston. Samples drawn from July 20th onwards were, judged by the routine bacterial tests, below the optimum London standard, but not to an extent which under normal conditions would have caused concern. A number of strains which attracted notice were carefully studied, but all were finally pronounced blameless. Several samples, when chemically tested, showed a relatively high chlorine figure. Assuming that the contagion, though present at first, had disappeared before the samples were taken, or else that it was present in the sampled water but, as may occur, eluded discovery, attention was turned to the connexions of the water main serving the stricken area. This pipe was found to be linked up by by-passes with the raw water supply of the adjoining Poplar gasworks, which is derived from the River Lea, and the view was expressed by Mr. J. R. Taylor, an engineering inspector of the Ministry, that under certain conditions of pumping and pressure it would have been possible for reflux raw water from the gasworks to get through the by-passes into the pure supply. The connexion of the two systems was very circuitous, and evidence was wanting that the conditions for reflux were actually operative at any time prior to the outbreak, but a possible channel of contamination appears to have existed, and the incidence of attack on the various streets was precisely such as might have been expected had infection been carried into the main at the suspected points. All communications between the pure and the impure have now been effectively severed. Dr. Hancock's report[1] on this strange sickness describes in a very interesting

[1] Ministry of Health. Reports on Public Health and Medical Subjects, No. 41. H.M. Stationery Office, or through any bookseller. Price 9d. net.

way his exploration of a baffling problem, and is published now, as Sir George Newman indicates in a prefatory note, in order to draw attention to the potential dangers of such water-main connexions.

GLUCOSONE AND ITS POSSIBLE SIGNIFICANCE IN METABOLISM.

DR. A. HYND recently communicated to the Royal Society a paper[1] on the action of glucosone on normal animals (mice) and its possible significance in metabolism. The work was carried out in the physiological laboratory of the University of St. Andrews, and the observations recorded are of interest to medical men generally. Dr. Hynd found that glucosone or aldofructose, an oxidation product of glucose or fructose, when injected into normal mice subcutaneously, produces in a few minutes a series of symptoms which are very similar to those brought about by an injection of insulin. The condition differs from that produced by insulin in that there is no hypoglycaemia, but it is modified by the use of adrenaline and pituitrin and by the previous injection of aceto-acetic acid. Dr. Hynd ventures the suggestion that glucosone is an intermediate stage in carbohydrate metabolism and that it is normally produced by the action of insulin. According to this view some of the symptoms produced by excess of insulin are really the results of the production of too much glucosone. If Dr. Hynd is right, glucosone may become an important substance in the treatment of those conditions for which insulin is at present prescribed, especially as it can be taken by mouth. Unfortunately the manufacture of pure glucosone is an expensive and complicated matter, and the methods hitherto adopted for production on a large scale by the hydrogen peroxide process result in its adulteration by other oxidation products which are harmful. Thannhauser and Jonke employed such preparations in the treatment of severe cases of diabetes, giving the syrup diluted by mineral waters. They found that it cleared up the glycosuria and the formation of acetone bodies, but could not be continued on account of intestinal complications—diarrhoea. They were probably working with a material which, in addition to glucosone, contained numerous other oxidation products of glucose. The pure glucosone, made by Fischer's process, does not appear to have any deleterious effect beyond that produced by an overdosage. Recovery from a non-lethal dose takes place very quickly and no after-effects are shown. Rats and rabbits have been tried since the paper was written, and these animals also react to glucosone in very much the same way that they do to insulin. The similar oxidation products of maltose and lactose—that is, maltosone and lactosone—are inactive, but when hydrolysed to glucosone give the effects of the latter.

THE INFLUENZAL CONSTITUTION.

A TRIBUTE was rendered to the prescience of Sydenham by Sir William Hamer at a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on April 29th, when he opened a discussion on the influenzal constitution by remarking that the events of the early nineties had done much to stimulate interest in the ideas for which Sydenham had stood. Sir William Hamer suggested that, epidemiologically, true influenza presented three features: (1) an average wave-length or interval between epidemics of one-third or two-thirds of a year at pandemic times; (2) a somewhat longer wave-length, which, owing to concomitant seasonal influences, tended to be about a year, eighteen months, or two years, for trailers and precursors nearly adjacent to the pandemic; (3) a still longer wave-length, which, when the average time from infection to infection became extended (as it apparently did, even to ten to fourteen days), might be estimated at some five to seven years in the trough between pandemics. He suggested that in the days of Sydenham the epidemiological problem might really have been simpler in that there might have been less development and differentiation of morbid types. He then reviewed the historical facts which illustrated the "*setting*" of epidemics of influenza, and remarked that modern writers "did not care to face 'brain fevers,' 'soporosités,' 'comatose fevers,' and 'fièvres pétéchiales'; they feared to struggle through the jungle of ship, camp, harvest, and gaol fevers of over two hundred years ago and to penetrate into the primeval forest of 'miliares,' 'fièvres pourprées,' 'fevers infestuous to the brain and nervous stock,' 'trousse-galants,' and 'sweats.' And yet, accepting the principle of continuity, and making allowances for changing terminology, 'settings' of influenza corresponding with those of to-day might be clearly discerned, and the notion emerged, firmly held by the epidemiologists of those times, that these prevalences made up constitutions." Referring to relapsing fever and typhus in relation to influenza, Sir William observed: "There is surely need here for recognizing the correlativity of these (symptom-complex) opposites, and realizing that they are 'inseparable elements of a higher (epidemiological) unity.'" The case might, he thought, be based on three grounds: (1) such individual correlations as the association of dysentery and typhoid in the war period, and also, in 1899-1901, with *influenzal* constitutions; (2) the oscillations of the curve of London fevers or even of "all causes" after exclusion of the zymotics; (3) the variability of the typhus symptom-complex. The practical lesson drawn was that more attention should be given to the less dramatic and obvious manifestations of influenza. It should be plainly stated that there was a moral obligation upon all who developed *influenza* to "take it lying down," and to refrain scrupulously, during the early infectious stages, from associating with other people, using public conveyances, and going to places of public assembly. Sir William Hamer believed that if the importance of this was fully realized, far more injury to the public health would be obviated than resulted at the present time from neglect of necessary precautions in all the "dangerous infectious diseases," among which, technically speaking, influenza was, as yet, not included.

PNEUMOCONIOSIS CAUSED BY ASBESTOS DUST.

DURING the conference of the Royal Microscopical Society at Liverpool, at the end of March, a case of pneumoconiosis due to asbestos dust was reported by Dr. W. E. Cooke and Mr. C. F. Hill. Although the asbestos industry is more than 2,000 years old, this case appears to be only the second reported, the first patient having died in the Charing Cross Hospital in 1900. In the present case the particles found in the lungs were large, some measuring as much as 350 microns in length; they were shown to represent the brittle iron-containing part of the asbestos fibres. Chemical analysis of the substance in the various stages of its manufacture, and of the dust, were correlated with the microscopical appearance. The dust contained 18 per cent. of iron as ferrous oxide, the raw material 2.1 per cent., and the finished article 0.1 per cent. The microscopical appearances of the dust were identical with those of the particles found in the lungs. A second interesting feature which aroused a good deal of discussion was the presence of a body which some thought was an aspergillus. The authors of the paper held the view that it was a hyphomycete analogous to that found by

[1] *Proceedings* of the Royal Society, B, vol. 101.

Dr. H. H. Scott in batrachians, or that it belonged to the tuberculariaceae, a family of hyphomycetes described by Ehrenberg in 1818. In the course of the conference Dr. Eric Ponder described the procedure whereby he had investigated the diameter of the red cells of man before and after exercise. The corpuscles immersed in plasma were examined and photographed in a special chamber containing a gas mixture in equilibrium with the blood at rest or after exercise. It was stated that no difference in the mean diameter of the cells appeared to be caused by even severe exercise.

THE PRODUCTION AND CONSUMPTION OF DANGEROUS DRUGS.

THE Advisory Committee of the League of Nations, which deals with the traffic in opium and other dangerous drugs, has recently issued a summary of annual reports for the years 1924 and 1925 received from various countries and mandated territories. In the case of Germany it appears that 152,000 kilograms of opium were imported in 1925 and some 14,000 kilograms of morphine were manufactured, of which 4,642 kilograms were exported. In Great Britain, in the same year, 68,541 kilograms (150,806 lb.) of raw opium were imported, and the novel feature recorded is that no less than 52,722 kilograms (116,000 lb.) of the total import came from India. Persian opium has almost ceased to be imported, and Turkish opium is falling off. Although Indian opium only contains 9.07 per cent. of morphine as against 11.03 per cent. in the Turkish drug, it is nevertheless found to be commercially a profitable source of the alkaloid. British exports of morphine in 1925 amounted to 95,285 ounces (2,706 kilograms), showing a considerable increase on the previous year. It is reported from Hong-Kong that 11 per cent. of the total revenue of the colony is derived from opium, that 41,600 lb. of raw opium and 28,000 lb. of opium "prepared" for smoking were imported, during 1925, from India. In Iraq the sale of opium has become a Government monopoly. In the case of the United States 100,478 lb. (45,667 kilograms) of raw opium were imported in 1925 from Turkey, Greece, and England; 105,689 ounces (3,001 kilograms) of morphine were manufactured, nearly all of which was used for home consumption. It is stated that no heroin was produced during the year, as its manufacture is now forbidden by the Federal Narcotics Control Board, but 154 kilograms of the alkaloid were sold in 1925. In 1924 the area under cultivation for the opium poppy in India was 54,708 hectares. The consumption of opium "prepared" for smoking in the years 1920-24 appears from the statistics to be enormous in Burma, Formosa, French Indo-China, Hong-Kong, Malaya, the Netherlands Indies, and Siam. It is clear that much remains to be done before the restriction of opium and other dangerous drugs to medical and legitimate purposes is achieved.

TEACHING OF INDUSTRIAL MEDICINE

SIR THOMAS LEGGE gave a Chadwick public lecture on the teaching of industrial medicine in the rooms of the Medical Society of London on May 3rd. He said that he considered that Charles Turner Thackrah, a medical practitioner of Leeds, Edwin Chadwick, and Dr. Southwood Smith laid the foundation of industrial medicine in this country a century ago. Unfortunately the work of the certifying factory surgeons—the outcome of their labours—became stereotyped on a too narrow negative basis by the Factory Act of 1844 and has so remained ever since. While the medical student cannot fail to learn a great deal about the maladies and accidents which strike down workpeople, little or nothing is done in the medical curriculum to link this knowledge up with their causes in the modern factory system. A right attitude of mind towards labour in the newly qualified medical man is an all-important factor in his equipment, but how many of them know that unless the employer has done everything (and everything means a good deal), the workman can do next to nothing to protect himself against the risks of his trade. The medical man should not have to embark on practice without even knowing the names of the eleven occupational diseases he is under a statutory obligation to notify. Over twenty others are scheduled under the Workmen's Compensation Act, the benefits of which are not easy to realize, unless the medical man looks upon it as his duty to his patient to tell him how to obtain them. But no one teaches this to the medical student. The newly qualified medical man is much more likely to be called on to give evidence at some inquest, the result of poisonous dust, gases, or fumes, than in a murder case, and forensic medicine teaching might stress the dramatic human interest in "gassing" cases and mine rescue work. The sheet anchor for the protection of workers against poisonous dusts and fumes is exhaust ventilation, applied as near as possible to the point of origin, and that against vitiated air from the aggregation of persons general mechanical ventilation by extraction fans. Sir Thomas Legge expressed his opinion that what was wanted most in the factory was preventive medicine on the clinical side—that is, by a practising doctor and not by an administrative medical officer.

ROYAL SOCIETY CONVERSAZIONE.

THE usual spring conversazione of the Royal Society was held on May 11th, in the Society's rooms at Burlington House, when the guests were received by the president, Sir Ernest Rutherford, O.M. The important advances now being made in microscopy were illustrated by Mr. J. E. Barnard, F.R.S., who showed two complete microscopical outfits for use with ultra-violet light, from the department of applied optics of the National Institute for Medical Research. One of these microscopes was the experimental one which was made and has been in use for some time in the department; the other was a finished model recently constructed by Messrs. R. and J. Beck. This form of microscope can be used either for transmitted light or for the investigation of filterable viruses by the dark-ground illumination method. Not only is increased "resolution" of the organisms obtained by the short wavelength used, but enhanced visibility is secured by this method of illumination. Magnification is now possible to 3,500 times, and accurate focusing and microphotography are possible at such small intervals as one-tenth of a micron. Spectrograms of the absorption by certain culture media of ultra-violet light were shown, and the efficiency of the apparatus was demonstrated by slides of the fine granules in silver films and of the organism of bovine pleuropneumonia. Dr. Thomas Lumsden showed a series of microscopical slides illustrating the effect of cytotoxic serums on cancer cells. He demonstrated that anti-human-cancer serum applied to cultures of mouse cancer, mouse heart, and mouse kidney killed the cancer cells within a few minutes; the normal tissues were undamaged and their staining reactions were not affected. It was also shown that mouse cancer cells grown in a rat could be cultured *in vitro* for two or three weeks in the serum of the rat host, but that this serum killed cultures of mouse cancer cells from a mouse; thus, the temporary sojourn in the rat had protected the mouse cancer cells introduced into it. Rat sarcoma cells could grow freely in the serum of a rat rendered immune to this tumour; the peritoneal exudate destroyed the cells but was harmless to normal rat tissues and to other tumour cells. The Natural History Museum showed skins of the African squirrel to illustrate how in rain forests the colour was nearly black;

in less dense woods, redder and brighter; on grass lands, greyer; and on the fringe of deserts, more yellow. It also exhibited balls made of disintegrated leaf fibres by the action of waves, and a hair-ball from the stomach of a horse. Mr. A. K. King demonstrated the application of ultra-violet radiation to the detection of impurities in distilled water, and the estimation of minute quantities of arsenic. The Astronomer Royal showed transparencies illustrating the sun's corona at four previous eclipses, and the National Physical Laboratory supplied a model of the shadow of the moon near the earth's surface, on the scale of ten miles to the inch, showing its dimensions, direction in space, and intersection with the earth's surface. Mr. G. H. Gabb showed the recently discovered astrological planisphere constructed for Queen Elizabeth about 1560-70, by Dr. John Dee, and engraved at the Royal Mint in the Tower by Humphrey Cole, who placed in its centre the arms of Elizabeth and her monogram, surrounded, in concentric circles, by the twelve astrological houses and months, with the zodiacal signs. During the Commonwealth this planisphere came into the hands of Henry Sutton, who in 1655 used the blank space on the reverse for the construction of a circular slide rule—the earliest dated "spiral" slide rule known. During the evening cinematograph films and lantern slides were shown by Mr. F. Martin Duncan, and Mr. D. Seth-Smith, by permission of the Zoological Society of London, to illustrate the courtship of birds. Sir Almroth Wright gave a demonstration of the phenomena of "intertraction."

DICTIONARY OF NATIONAL BIOGRAPHY.

A NEW volume of the *Dictionary of National Biography* is to be published this year. Few men have raised a better memorial to themselves, doing at the same time honour to the calling they follow, than George Smith, head of the firm of Smith, Elder and Co., when, in 1882, he began the publication of the *Dictionary of National Biography*; it appeared in sixty-three quarterly volumes between 1885 and 1900. George Smith was fortunate in securing the services as editor of Sir Leslie Stephen, under whose guidance the first twenty-one volumes were published. The next six were edited by him and Sir Sidney Lee, and the remaining volumes by the latter alone. As the plan was to make the original issue cover the names of all British notabilities down to the end of the nineteenth century, it followed that the names of a certain number of persons who died during that century could not be included in their proper alphabetical order; for these a supplement, also edited by Sir Sidney Lee, was published (1901-2), forming volumes lxiv to lxvi, and in it was included the biography of Queen Victoria, who died on January 22nd, 1901. In 1908 and 1909 the sixty-six volumes were reissued, with some corrections, on thinner paper in twenty-two volumes. Later on the publication was transferred to the Oxford University Press, by which it is now issued. A new series was begun with the issue of the second supplement covering the years 1901-1911, and the Press hopes to publish in the course of this year another new volume covering the years 1912-1921. It is edited by the Regius Professor of Modern History at Oxford (H. W. C. Davies) and by Mr. J. R. H. Weaver, of Trinity College, Oxford. It is intended to publish a new volume every ten years; that now nearly ready for publication has 269 contributors, nine of them women, and the names of nearly all those included in it are familiar to everyone acquainted with the events of this century. Among the medical names are those of Lord Lister (Sir John Rose Bradford), Sir William Osler (Sir Archibald Garrod), Mrs. Elizabeth Garrett Anderson (Miss F. C. Johnson), and Sir Leander Starr Jameson (Mr. D. O. Malcolm). An alphabetical index to the whole of the century so far (that is, 1901-1921) will be appended.

THE WOOLWICH MEMORIAL HOSPITAL.

THE next few weeks will see the completion of a notable addition to the hospitals of London, for the first section of the new hospital erected by the trustees of the Woolwich War Memorial Fund is almost finished and should be ready to receive patients in a month or so. Those who have travelled the Dover Road during the last few months cannot fail to have noticed the handsome building crowning the summit of Shooter's Hill, and the hospital authorities are to be congratulated upon their prescience and enterprise in securing such an attractive and unusual site; one, moreover, which amply provides for all conceivable extensions of the hospital, for it consists of no less than 13 acres of freehold land. Among the hills of London and its environs Shooter's Hill has always held high rank, first for the quality of its air and the quantity of its sunshine, and secondly for the remarkable panorama visible from its summit on a clear day. The highest point of the hill, which is actually in the hospital grounds, is 422 feet above sea-level, and to look round from there, or better still from the roof of one of the ward blocks, is an arresting experience. To the north, spreading up to the foot of the hill, are the densely populated districts of Woolwich and Plumstead—all churches, chimneys, trams, and houses; then the winding reaches of the Thames, with all its busy shipping, and, in the distance, the hills of Essex. To the south Eltham, Mottingham, Sidcup, and Chislehurst look little more than villages from that height—and even they are lost in the wide expanse of mile upon mile of smiling Kentish countryside, with its trees and fields and orchards stretching away to the far distant southern Downs.

An exceptional site demands an exceptional building, and the architects, Messrs. Pite and Fairweather, have taken full advantage of an unusual opportunity, for they have produced a gracious, dignified group of buildings planned with real distinction. Following the contours of the sloping ground the main corridor of the hospital curves east and west along the brow of the hill, and in the slight concavity so formed on the northern side are the administrative block, the operating theatre block, power house, etc. The convex side is left free for the ward blocks, which project at right angles from the main corridor, and so are directed south towards Kent and the sun. A feature of the ward blocks is the provision of commodious sun balconies, so arranged as to allow of patients remaining out no matter what the weather.

The ultimate aim that the Memorial Fund Committee has in view is a fully equipped general hospital of 320 beds. £180,000 has already been collected—practically enough to cover the total cost of the first section of the hospital, consisting of administrative block, residents' quarters, operating theatre block, power house, pathological block, x-ray department, maternity unit, and two ward units, each consisting of two wards of 26 beds each, with further accommodation for 6 beds on the balcony of each ward. The next section to be built will consist of two further ward blocks, a paying patients' pavilion, and the nurses' home, the nurses meanwhile being housed in the main building. Everything has been designed in such a way that future additions will entail no interference with the existing units. They will merely be attached at points already carefully planned, and all essential services, such as drainage, electricity, steam, and water supply, are provided for on the basis of what the demand will finally be when the whole scheme is completed.

The Woolwich Memorial Hospital is a metropolitan hospital in the country, or nearly in the country—certainly one of the best bits of country to be found within twenty-five minutes' drive of Charing Cross; and it will be very interesting to watch the development of what is the first experiment of its kind—a general hospital built, staffed, and equipped on the same lines as any other important London hospital, with a large industrial population almost at its doors, but so situated that problems of light, air and sunshine, and adequate space for development can arouse no apprehension. Lord Dawson and Sir Berkeley Moynihan have consented to act as consultants, and this sets a high standard for the remainder of the honorary staff who are about to be appointed.

South Africa.

[FROM OUR CORRESPONDENT IN PRETORIA.]

ANNUAL REPORT ON PUBLIC HEALTH.

By Act of Parliament there was established in 1919 a Department of Public Health under the control of a Minister. An abridged report of the work and activities of this department is prepared annually by the Secretary for Public Health (Dr. J. Alexander Mitchell), and appears along with similar reports by the secretaries of the other Government departments in the volume of Annual Departmental Reports. The volume is published during the Parliamentary session and presented to both Houses of Parliament.

Public Health Organization of the Union.

Under the Public Health Act of 1919 there was established a Council of Public Health to advise the Minister and Department—the Minister being chairman and the chief health officer for the Union deputy chairman. Of the remaining seven members (none of whom may be officers in the public service) four are medical practitioners. These members hold office for three years. The members of the five-year period ended on June 30th, 1925. The members were Miss Mabel Elliott; Drs. Charles Porter J. H. Nicolson and M. C. Vos; Drs. Charles Porter and W. Watkins-Pitchford. Miss Kock, E. Hill, and W. Watkins-Pitchford. Miss has since resigned, and has been succeeded by Mrs. Dr. Watkins-Pitchford was succeeded on his ment from the South African Institute for Medical ch by Sir Spencer Lister, the director.

The departmental staff consists of the Secretary for Health, who is also chief health officer for the and six assistant health officers. Of the latter, four heir headquarters in Pretoria, the administrative of the Union, one is stationed at Capetown, and Durban, Natal. In addition there are pathologists, lth officers, and inspectors.

t surgeons are appointed for Government medical connexion with accidents, assaults, and other gal cases, paupers, and medical attendance on gaol officials. Under the present law the Govern- t responsible for providing medical facilities for public; but district surgeons' appointments are e so as to fit in as far as reasonably possible with ts of the public, provided no extra cost is ast year there were 282 district surgeons; of are whole-time officers—namely, two each at d Durban, and one each at Capetown, Port d East London. Four are whole-time officers ntly with local authorities or public bodies— Kimberley, Grahamstown, Queenstown, and e remaining 271 render part-time service to nt, being usually general practitioners in ts.

al authority may, with assistance from the ppoint a medical officer of health. Of the authorities, the following employ whole-time of health—namely, Johannesburg, East London, Durban, Pietermaritzburg, East London, eth; four have medical officers of health blic appointments, but doing no private remainder, many pay local private practi- ining fees to perform such local public nay arise. Fifty-two of the urban local certificated sanitary inspectors devoting ime to sanitary work.

Plague.

the year under review (1925-26) was noteworthy feature being the exten- infection amongst the veld rodents of pe districts. This enzoötic plague is inland districts. Fortunately, the ry shy of man, is nocturnal in its very rarely been found in railway nveyance of plague infection to the areas where infection is enzoötic is, therefore, very slight. The risk of introduction of plague from outside the Union is, however, great. No actual or suspected plague in man or rodents occurred in the Union ports during the year. The greatest vigilance is maintained, systematic bacteriological examinations of rodents are carried out, and continued efforts are made to keen down the rodent population of the ports. An improv rat-guard has been devised by the department for moorir cables. Tests proved this guard to be more effective i preventing migration of rats either to or from vessels thai any hitherto employed, and its use has been made com- pulsory, by regulation, in respect of vessels recently arrived from plague-infected or suspected ports. Shipping com- panies and all concerned have been furnished with drawings and specifications, and arrangements were made by the department with certain firms for the manufacture and supply of these guards.

The number of cases of human plague during the year under review was small compared with previous years. There were in all only 71 cases, of which 46 proved fatal, 86 per cent. of the cases were of the bubonic type, 10 per cent. pneumonic, and 4 per cent. mixed pneumonic and bubonic. Synchronizing with an extensive epizoötic among gerbilles, multimammate mice and hares, an extensive and scattered epidemic occurred at the beginning of 1926 on fourteen different farms in the Orange Free State; 37 cases, including 8 of Europeans, were notified, with 26 deaths. The history of one European family, in which 5 cases occurred, is very typical. At their farm many dead gerbilles were found, and several natives contracted plague. A little later the owner of the farm became infected. He was attended during his ten-day illness by his brother and sister, and visited by many friends. On his death these people were notified by the district surgeon that they were under quarantine, and were not to leave the farm. Two days later the brother contracted pneumonic plague. His mother and two sisters became infected through nursing and kissing him, and all died within a week.

Another outbreak occurred in the eastern Cape Province, resulting in 12 cases with 9 deaths; 4 of these were among Europeans belonging to the same family. The son of the farmer was an enthusiastic hunter of hares and other small animals. Dead hares and field-mice had been observed on the veld shortly before he sickened. He remarked one day on the number of fleas that he had brought in with him from the veld. Soon after he developed a bubo below the shoulder-blade and died on the sixth day. Before his death he was kissed by his father and mother; both were down a few days later with pneumonic plague, and were dead within a week. Two days after the death of the mother the daughter developed pneumonic plague and died six days later.

The report gives an account of the flea, rodent, and plague research which has been carried on. This work has been previously described in the BRITISH MEDICAL JOURNAL (June 5th, 1926, p. 962, and August 7th, p. 269), including the discovery of the very interesting "Tiger River disease." The causative bacillus appears capable only of attacking small veld rodents, and it has not been found possible to infect hares, ground squirrels, rabbits, suricates, domestic rats, guinea-pigs, mongooses, cats, dogs, or monkeys with this disease.

Leprosy.

It had been intended three years ago to make a systematic leprosy survey of the Union, with a view to ascertaining the position as accurately as possible. Shortage of staff and financial circumstances have rendered this impossible, but during 1924 all magistrates and district surgeons were circularized and requested to inquire into the matter. From information so obtained fairly detailed tables have been prepared. During the fifteen-year period ended June, 1924, the number of lepers discovered and certified in the Union was 5,162. It is estimated that at least 1,630 lepers remained at large, unknown and uncertified, at the end of that period, bringing the total to 6,792. The estimate of uncertified cases was probably on the low side, owing to the magistrates not taking sufficient account of cases in the early stages and still without disfigurement or obvious symptoms. The average number of new cases discovered annually was approximately 450. The

average period elapsing between onset of the disease and segregation was about six and a half years. Efforts have been made to reduce this period, but it is still at least five years. Assuming that, as is probable, the annual number of new cases developing remains at about 450, then this figure multiplied by 5 gives an idea of the number of cases in various stages at present at large and undiscovered. Assuming, then, that there are about 2,000 undiscovered cases, the general position of the Union in 1924 is as follows:

Certified lepers in the six institutions	2,141
Certified lepers, home-segregated	24
Certified lepers awaiting removal	100
Probationally discharged lepers	905
Uncertified lepers	2,000
Total number of lepers in the Union ...	5,170
Leprosy rate per 100,000 of population ...	70

The detailed tables reveal many points of interest. The anaesthetic type predominates amongst native cases, the nodular and mixed types amongst Europeans and Eurafricans. In a large proportion of cases a history of direct association with previous cases was elicited. The average age on first admission is 33. In a large percentage of cases the skin symptoms were those first noticed. The proportion of lepers giving a history of association with previous cases in the same family is certainly much understated in the tables, as leper patients are notoriously apt to conceal facts of this kind. Further examination of associated cases and family groups is being carried on, and a number of family trees are being prepared. This should throw useful light on the modes of spread and conditions favouring spread. So far the results support the views of Sir Leonard Rogers and his co-workers—that in the great majority of cases infection takes place in childhood or early adult life, and that the association of infective lepers with children and young people is much more dangerous than their association with older persons. The early years of the disease are as a rule the most infective, and during the long period—usually about six years—the cases of infective type have been associating freely with their families and others, and spreading the infection. It is evident that until some system or method is devised by which early discovery can be secured and precautions instituted, the spread of the disease cannot be effectively limited. Compulsion will never effect this; the voluntary co-operation of the native peoples must be secured.

Since the introduction, some years ago, of the Leprosy Board system only active and actually or presumably infective cases are segregated in institutions; the accommodation in the six institutions is now ample, and the annual expenditure on leprosy has been considerably reduced. With few exceptions all the patients in these institutions are now receiving active antileprotic treatment by various modern methods.

Malaria.

Except for serious localized prevalence in Zululand and the Northern Transvaal, there was but little prevalence of malaria in the endemic areas. Natives recruited from endemic areas in Zululand appeared to be relatively immune, and are at an advantage compared with other natives when employed in railway construction in malarious areas.

A long-overdue anopheline survey of the Union is in contemplation. Little progress in this direction has been made since 1905, when *A. costalis* was proved to be the main vector of a serious epidemic in Natal. The proposed survey is to be undertaken jointly by the Division of Veterinary Research and the South African Institute for Medical Research, with the co-operation of the Department of Public Health. Some work was done by the institute and the department during the year. Six species of anophelines were identified as occurring in the Hartebeestpoort irrigable area, near Pretoria.

Typhus Fever.

Of the 1,135 cases of typhus fever that occurred in the Union during the year under review 55 were among Europeans, with one death, and 1,080 among non-Europeans, with 145 deaths. The disease was comparatively quiescent, though unreported outbreaks probably occurred in some of the Transkeian districts. Sporadic cases were detected in Durban by the routine application of the Weil-Felix test to all specimens of blood received in the laboratory; these early diagnoses were often subsequently confirmed clinically. The symptoms of the form of the disease usually met with in South Africa are often obscure and indefinite, and its diagnosis is frequently difficult, so that unless special care is taken and a sharp look-out kept, cases are very liable to go unrecognized and unreported.

England and Wales.

RUTHERFORD MORISON TESTIMONIAL FUND.

THE Rutherford Morison Testimonial Fund has now been closed and the accounts presented by the honorary treasurer, Mr. R. J. Willan, M.S., F.R.C.S., have been duly audited. The total amount received in subscriptions was £1,523 9s. 6d. The cost of the portrait, including the fee to the artist (Mr. Harold Knight) and the price of 100 photogravures with incidental expenses, including printing and stationery, amounted to £458. This left a sum of £1,206, which was handed over to Mr. Rutherford Morison and paid by him to the Council of the University of Durham College of Medicine, who will administer the travelling surgical scholarship which was the purpose to which Professor Morison desired the fund to be devoted. The scholarship will be available for candidates proposing to take the degree of Doctor of Surgery (D.Ch.) in the University of Durham, and it is intended that the holder should undertake at least six months' surgical study abroad. The income of the trust will be allowed to accumulate for three years, and the first award will be made in 1929. The scholar will be nominated by a committee consisting of the professors of surgery, anatomy, physiology, and pathology and bacteriology, together with one member of the honorary medical and surgical staff of the Royal Victoria Infirmary. We may congratulate Mr. Rutherford Morison on this very striking tribute to the esteem in which he is held and to the great respect which he has inspired as a surgeon, teacher, and a man. We may also congratulate him on the purpose to which he devoted the fund; everyone will agree that a period of observation abroad is of the greatest advantage to a young surgeon; it is, in fact, becoming more and more necessary. The habit once acquired is not likely to be lost, and there are already in existence several societies of surgeons the main object of which is to afford opportunities for visiting surgical centres at home and abroad.

RHEUMATIC HEART DISEASE IN CHILDREN.

The London County Council, on May 10th, had before it a report by the Public Health Committee on the need for beds for chronic cases of rheumatic heart disease in children. The report followed upon a reference of this subject to the committee, moved in the Council some weeks ago by Dr. Stella Churchill. The report repeats the statements and figures which were given recently in a report of the Metropolitan Asylums Board (BRITISH MEDICAL JOURNAL, April 23rd, p. 776), and relates the circumstances which led up to the proposed extension of Queen Mary's Hospital at Carshalton, where 350 beds will presently be available for these cases. The committee states that this additional accommodation will very materially assist the solution of the problem of the convalescent treatment of the rheumatic child, and when the permanent addition to St. Mary's Hospital is completed there should be no question of the adequacy of the provision made. The Public Health Committee has expressed to the Metropolitan Asylums Board its appreciation of the steps it has taken.

HOSPITAL EXTENSIONS IN NOTTINGHAM.

Princess Mary visited Nottingham on April 30th, and opened the Rope Walk wing of the Nottingham General Hospital and the new buildings of the Children's Hospital. The Rope Walk wing contains a waiting-hall for 500 outpatients, with consulting rooms opening into it, and a dispensary on the same floor. There are also *x*-ray,

orthopaedic, and electro-therapeutic departments. The first floor is devoted to diseases of the ear, nose, and throat, and additional beds for forty patients have been made available. The Rope Walk wing has taken some three years to erect and equip; the cost was £100,000, half of which was presented by Mr. W. G. Player, J.P. Many of those who were present at the Annual Meeting of the British Medical Association last year were able to examine the buildings, then approaching completion, and to appreciate for themselves the great value of this addition to an enterprising hospital. The new premises of the Children's Hospital will accommodate eighty patients, but the work of extension will not be completed for some time yet. The new building consists of a basement and three floors; ample provision has been made for open-air treatment, and the windows of the wards contain glass permeable to ultra-violet rays. It is proposed to extend and bring up to date the present out-patients' department and to provide a separate building for massage and treatment by ultra-violet rays.

OUTBREAK OF SMALL-POX AT HENDON.

The recent occurrence of nine cases of small-pox at Hendon is noteworthy in view of the severity of the infection. From information supplied by Dr. T. S. McIntosh, medical officer of health for Hendon, it would appear that the first patient was a man, aged 47, who had been vaccinated in infancy. Although his illness did not take a grave form, it was not of the mild type prevailing elsewhere in England; the source of the infection has not been traced. His wife, aged 42, who had not been vaccinated since infancy, contracted the disease severely, but is believed to be convalescent. Two daughters aged, respectively, 16 and 8, became infected; both were unvaccinated and the infection ran a severe course. The elder died, the disease being of the confluent fatal type, but it is hoped that the younger may recover. Four workers in the laundry to which the linen from this family had been sent developed small-pox, and three died. Two of these, aged 38 and 15, were unvaccinated, and the disease was of the confluent fatal type. The third was a rapidly fatal case of haemorrhagic small-pox in a woman, aged 23, who had only been vaccinated in infancy. She gave birth to a premature live child on the morning of the day on which the diagnosis was made. The infant developed small-pox papules a week after birth, coincident with the appearance of vaccination vesicles, and died five days later. The fourth worker in the laundry was an unvaccinated woman, aged 21. She was vaccinated after the onset of the first symptoms and vesicles appeared about the same time as the small-pox eruption. The case is of moderate severity and the patient is expected to recover.

Scotland.

EXTENSION OF RADIOLOGICAL FACILITIES AT EDINBURGH ROYAL INFIRMARY.

SOME six months ago a very elaborate electrical department was opened at the Royal Infirmary of Edinburgh; in addition to the most modern radiological apparatus, it has departments for medical electricity, massage, and exercise-therapy. It has been suggested that the benefits of this department might be available for persons other than the patients in the institution or those attending the various out-patient departments. Such facilities are not available for the public in Edinburgh and the area of which it is the medical centre. It has therefore been decided to receive patients who are under the care of outside practitioners in this department of the hospital. To some it seems as though this were the first step towards making the benefits of the Infirmary generally available to all classes of the community, or, in other words, the establishment of a section for paying patients; this, many persons regard as highly desirable. The conditions under which these benefits are now available are as follows:

The managers of the Royal Infirmary have decided to extend facilities to medical practitioners for the examination or treatment by the radiologist of patients who are unable to pay the usual private fees; and to others for treatment by apparatus and appliances not otherwise available in the city or district. Requisition forms can be obtained at the superintendent's office. These must be completed and forwarded, together with a short history of the case, to the superintendent, who will make an appointment for the attendance of the patient and forward details of any necessary preparation. It is expected that the patient will give an appropriate donation to the hospital in order to help to defray the necessary expense incurred. The amount of such donation will be adjusted by the superintendent after consultation with the private medical attendant.

THE ASTLEY-AINSLIE INSTITUTION, EDINBURGH.

The Astley-Ainslie Institution was founded through a bequest by the late Mr. David Ainslie of Costerton, "for the relief and behoof of the convalescents in the Royal Infirmary." It is under the control of a board of governors, nominated by various public bodies in Edinburgh, whose policy is to deal with patients whose convalescence is likely to be prolonged, but who may be expected eventually to regain health and to resume their ordinary avocations. An important aspect of the work of the institution is the scientific investigation of the process of "convalescence," on lines similar to those followed in the study of the inception and progress of disease. The governors have secured a site of over thirty acres, on the southern slope of the hill in the Grange district, with an exposure to the south, well wooded, and with an uninterrupted view of the Pentland and Braid Hills. It is interesting at the moment to recall that the property includes the house and policies of Millbank, the residence of James Syme, and the home from which Lord Lister took his wife. A unit, for female patients, has been in use since 1923. The remainder of the institution is under construction. The wards are built on the "butterfly pavilion" system, first, we believe, introduced by Sir Robert Philip in the Tuberculosis Sanatorium, for the designing of which he was responsible. Each pavilion has wide balconies, and the new scheme includes an administrative block, a nurses' home, central kitchen, power station, and a scientific block containing the radiological and electrical department, a gymnasium for treatment by physical exercises, a dental department, a research laboratory, and other accessories. Sun baths and shelters for open-air treatment are erected in the grounds. When completed the institution will accommodate about 150 patients. The cost of maintenance is borne entirely by the funds bequeathed by Mr. Ainslie.

SLUM CLEARANCE IN SCOTLAND.

At a conference of representatives of local authorities in Scotland, held in Glasgow last week, the slum clearance problem and town-planning in Scotland were discussed. A paper was read by Mr. John Bryce, director of housing for Glasgow, in which he reviewed the various slum clearance activities in Glasgow since 1923, which had involved an expenditure of more than £1,000,000. He said that the situation bristled with difficulties, being mixed up with complications in regard to wages, cost of land, insanitary conditions, drink, dirt, disease, crime, greed, maladministration, and the necessity for effective control. In every scheme for rehousing dispossessed tenants a caretaker was on duty who took an interest in the moral and physical welfare of the tenants, and saw that they kept their houses in order and obeyed the rules and regulations. Usually these caretakers had to educate the tenants to a higher standard of living, and they reported periodically to the manager of the City Improvement Department. Dr. William Robertson, M.O.H. for Edinburgh, dealt with the subject from the public health point of view. The vital statistics, he said, were always influenced by the slums, for people who grew up in slums were bad resisters of disease. The sanitarian of fifty years hence would reap the benefits that would accrue from the efforts now being directed against slums. Dr. Macgregor, M.O.H. for Glasgow, in the course of the discussion, remarked that the clearance of slums resulted in several benefits, including reduction in the proportion of one-apartment houses, the demolition of frankly insanitary houses, and the removal of a certain amount of overcrowding, for somewhere about 10 per cent. of the slum houses which had

been demolished in Glasgow had contained two families. Mr. G. D. MacNiven, F.R.I.B.A., of the Scottish Board of Health, Edinburgh, dealt with the present position of town-planning in Scotland, which he said was far from satisfactory. The first town-planning Act had been passed in 1909, but so far only two schemes had been approved by the Scottish Board of Health. The war, to a certain extent, necessitated the postponement of work in this direction, and since 1919 pressure of work in connexion with urgent housing questions had monopolized attention. He suggested that co-operation and joint action by several local authorities lay at the root of town-planning, and that regional planning was a better title. A conference of local authorities in the Clyde Valley was to be held in Glasgow on May 20th, under the chairmanship of Dr. W. E. Elliot, Under-Secretary of State for Scotland, and it was hoped that the whole subject as it affected that area would then be dealt with.

Glasgow Ear, Nose and Throat Hospital.

At the annual meeting of the Glasgow Ear, Nose and Throat Hospital, held on April 27th, Lord Provost Mason presided. The hospital has recently moved into new quarters in St. Vincent Street and attendances have greatly increased. The numbers for the ten months ending December 31st, 1926, were 25,430, which was 2,129 more than the total for the whole preceding twelve months, and 8,593 patients had been treated as compared with 7,202 in the previous year. Indoor patients for the ten months numbered 928, as compared with 480 in the previous year. The income for the ten months had exceeded the expenditure by £649. Lord Provost Mason remarked that the hospital was now one of the most up-to-date and highly equipped institutions of its kind in the country, and quoted Mr. Neville Chamberlain as saying that this was a perfect example of what a hospital should be. £60,000 had been raised in order to erect and equip it, and it had started its career free from capital debt.

Ireland.

Medical Register for the Irish Free State.

The Medical Practitioners Bill (1927) was read a second time in the Dail on May 5th. The bill gives effect to an agreement which was signed by Lord Balfour on behalf of the British Government, by Sir Dawson Bates on behalf of the Government of Northern Ireland, and by Mr. McGilligan on behalf of the Free State Government. This agreement forms a schedule to the bill. The agreement provides, among other matters:

1. That the nomination of a member of the General Medical Council, formerly made for Ireland by His Majesty, with the advice of the Privy Council, shall henceforth be made by His Majesty in Council on the recommendation of the Governor of Northern Ireland.

2. The nominations of members of the General Medical Council by universities and medical corporations in Ireland and the election of a member of the General Medical Council by registered medical practitioners in Ireland shall henceforth be made and had in the same manner as they formerly were.

3. Subject to the provisions of the agreement, the constitution of the General Medical Council and of the several branch councils as formerly existing under the Medical Acts, and the powers of holding qualifying examinations and granting diplomas for the purpose of registration in the General Register, formerly vested in certain universities and medical corporations in Ireland, shall be deemed not to have been affected by the establishment of the Irish Free State or of Northern Ireland, and for the purpose of the preparation and keeping of the general *Medical Register* the General Medical Council and the Branch Council for Ireland, and their respective officers, shall have, and may exercise in relation to persons, universities, medical corporations, and matters in the Irish Free State or in Northern Ireland, all such powers, jurisdictions, and authorities under the Medical Acts as the said councils respectively, and their respective officers, formerly had, and might exercise, under the Medical Acts for that purpose in Ireland.

Any person who is or shall be registered in the general register shall be entitled on payment of a fee prescribed by the Free State Parliament, to be registered in the *Irish Free State Medical Register*, provided that no fee shall be payable by any person who, on the date of the establishment of the *Free State Register*, is registered in the general *Medical Register*, and applies for registration in the *Free State Register* in such time and manner as may be prescribed by the Oireachtas. No person whose name has been erased from the *Free State Register* on account of his conviction of a felony, misdemeanour, etc., or his having been judged by the Free State Medical Council to have been guilty of infamous conduct in a professional respect, shall be entitled to be subsequently registered in the *Free State Register* by reason of his being registered in the general *Medical Register*. A person not previously registered in the *Free State Register* shall not be entitled to be registered therein if his name has been erased from the general *Medical Register* for a felony, misdemeanour, etc., or infamous conduct. With a view to preventing the holding of simultaneous inquiries the General Medical Council shall report to the Free State Medical Council every case in which it proposes, in connexion with the exercise of its disciplinary powers, to hold an inquiry into the conduct, in Great Britain or in Northern Ireland, of any person registered in the *Free State Register*, and the Free State Council will similarly report to the General Medical Council every case in which it proposes to hold an inquiry into the conduct in the Free State of any persons registered in the general *Medical Register*. On the receipt by either of such a report it (Council) shall have regard to the desirability of postponing its inquiry into the matter pending the completion of the inquiry by the other body. In the same way erasures from either *Register* shall be notified by one Council to the other.

The Medical Registration Council proposed to be established for the Free State will consist of nine members: (*a*) one nominated by the Executive Council of the Free State Government, (*b*) one nominated by each of the following bodies —that is to say, University College (Dublin), University College (Cork), University College (Galway), the University of Dublin, and the Apothecaries' Hall of Ireland, (*c*) one nominated jointly by the Royal College of Surgeons in Ireland and the Royal College of Physicians of Ireland, and (*d*) two who are registered medical practitioners in Saorstat Eireann shall be elected by the persons who are for the time being registered medical practitioners resident in Saorstat Eireann. The members of the Council shall hold office for five years. Casual vacancies will be filled by the bodies entitled to representation with the exception of that of a direct representative, when the Council shall fill the vacancy for the unexpired term of office. Every person already registered in the general *Medical Register* will be registered without payment of a fee in the *Free State Register* if the application is made within one month after the establishment of the register. There will be also provided a separate list in the *Free State Medical Register* for any person who is registered as a medical and surgical practitioner in any British possession, self-governing Dominion, or foreign country on conditions more or less similar to those that apply to the Colonial List in the general *Medical Register*.

Correspondence.

PROPHYLACTIC VACCINATION OF THE NEWLY BORN AGAINST TUBERCULOSIS.

Sir,—Your judicial article on prophylactic vaccination of the newly born against tuberculosis (Journal, May 7th, p. 845) leads me to amplify the statistical information contained in Professor Calmette's article. Of M. Moine's section I say nothing, for I have not examined his data, but Dr. Biraud's data I have examined, and I think that the condensed form of his report—or of Professor Calmette's presentation of his report—may lead to misapprehension. In the first place, readers not familiar with the method of practical life-table construction might possibly suppose that Dr. Biraud's results are based upon 1,877 infants observed from birth to death or until the expiration of two years from birth, whichever event happened first. This is not so, for children passed out of observation for various reasons—for example, some of them might have been vaccinated within a few months of making the analysis, or no particulars might be available as to what happened to them after a few months from birth. In fact, the "exposed to risk" had dwindled to 679 by the end of the eighth month, and to 367 by the end of the twelfth month, so that the basis of discussion becomes, within a few months of birth, rather scanty. It is further to be remarked that

con the rate of mortality of the
l that of the general population is
f life, that is, in a period when the
have followed the theory of the
ffect, good or bad, upon resistance.
ing that no selective factor such
your article biased the data, Dr.
es it probable that the mortality
of the vaccinated children was no
inary children. Hence, if it could
of mortality upon children of the
l was very much worse than the
case in favour of the value of the

' OF DIABETICS AS HOSPITAL
UT-PATIENTS.

a little space to join in the plea of
e of May 7th (p. 831), that diabetic
e treated in special clinics and not
ient departments of hospitals? His
ows how successful such a plan can
be, while the difficulty of obtaining good results in the general out-patient departments is known to all physicians. As the clinical control of these cases is undoubtedly based on laboratory tests, the best results can be obtained only in close touch with a laboratory. Many hospitals have been quick to recognize this in establishing such diabetic clinics, and the benefit to the patients and the increased efficiency of the work has been an immediate reward in every case.

I think Dr. Earl has understated the possibilities of what can be done in such clinics. It would appear from his article that the out-patient clinic which he describes at Salford Royal Hospital does not undertake the initial treatment of any case with "ketosis or a short acute history" or "any case which requires insulin," such cases being admitted to the wards. At a similar diabetic clinic at King's College Hospital, London, we are in the habit of treating practically all such cases from the start as out-patients, with the exception of cases of coma, children under 16, those who live at too great a distance to attend hospital daily, and the intensely stupid patients. Two or three years ago we undertook insulin cases as out-patients with some trepidation, and mainly because of the lack of beds in the wards and the necessity of immediate treatment. But their treatment as out-patients has been so uniformly successful that we find admission to hospital unnecessary except for the above-mentioned types. Over fifty insulin cases have been started successfully in this way without any untoward results. It has been found possible to institute an accurate diet within a day or two and to entrust the patients with their own injections after at most a week. Some, indeed, take charge of their own injections after the first one. Most of the patients appreciate the fact that they need not interrupt their ordinary life entirely by admission to the hospital. We find, too, that, having been largely on their own responsibility in their own homes from the commencement, they learn the ways of "the diabetic life" with thoroughness and self-confidence.—I am, etc.,

R. D. LAWRENCE, M.D., M.R.C.P.
Biochemical Department, King's College Hospital, London, May 7th.

TRAUMA AS A CAUSE OF AURICULAR FIBRILLATION.

SIR,—The interesting article on the above subject by Professor John Hay and Dr. Wallace Jones seemed to me a direct incitement to litigation under the Workmen's Compensation Act, which I very much deprecate. I therefore wish them to show not merely that auricular fibrillation in an apparently healthy heart has been part of a sequence following trauma, but what is the mechanism of its production, and what part has the autonomic nervous system played. A mere sequence of events is no proof of cause and effect.

It is not always easy to say what is a healthy heart. It is the simplest matter possible to pass an insurance examiner as a first-class life, but that is no evidence of the heart's capacity for any particular strain.

In my own case I have never been able to produce auricular fibrillation, no matter what the stress to which I have submitted my heart. In hill-climbing I can easily double the frequency of the beats, but no fibrillation.

On the other hand, I have known several, especially ladies, who with apparently healthy hearts get fibrillation on comparatively slight exertion. However, auricular fibrillation is divested of many of its terrors when you know that an attack can be arrested in about five minutes by the induction of the cardiac reflex of contraction.—I am, etc.,

Vichy, France, May 4th. JAMES BARR.

SIR,—I am interested in the letter from Dr. Harris (April 30th, p. 817), and am glad to find that he is in cordial agreement with our main contention, that sudden strain may induce auricular fibrillation in a heart predisposed to fibrillation by disease.

At this point, however, he comes to a full stop; and when we venture to say that "fibrillation may result from

physical strain in hearts that are apparently normal, so far as can be determined by ordinary clinical methods," Dr. Harris stigmatizes this guarded opinion as a "sweeping assertion," revealing himself as peculiarly lacking in a certain sense of proportion.

He evidently takes the view that fibrillation cannot occur in the absence of some pathological change and, in the presence of fibrillation, he would accept that—*in itself*, and alone—as evidence that the heart is diseased. In other words, fibrillation is all that is required for a diagnosis of myocardial damage. He sums up by saying that "there is no shred of dependable evidence produced which would suggest that trauma may produce fibrillation in a healthy heart." I am not sure to what he refers. It is not clear whether he suggests that we have not produced any evidence that the hearts of the patients we examined were normal, or whether he means that there is no dependable evidence of the experimental production of fibrillation by trauma in a healthy animal.

In so far as our cases are concerned, no lack of cardiac reserve was revealed on ordinary clinical examination, no enlargement of the heart that could be considered pathological, no evidence of valvular disease, nothing abnormal in the heart sounds, and no deviation beyond normal limits in the blood pressure. It was on these grounds that we felt justified in saying that the hearts were "normal so far as could be determined by ordinary clinical methods." With regard to the cases which we electro-cardiographed, I think, perhaps, Dr. Harris is inclined to lay more stress than is wise on such deviations from the normal as a slight slurring of the R deflection. In Case v, of course, the heart was admittedly damaged and the electro-cardiogram was frankly abnormal.

I cannot believe that Dr. Harris means that there has been no dependable evidence proving that fibrillation cannot be produced experimentally in a healthy heart, because many and various forms of stimulus—either chemical, electrical, or mechanical—are well known to start fibrillation of the auricles in the sound heart of an animal. The vital change is physiological and not pathological. Fibrillation is a functional disorder. Disease may predispose to fibrillation, but certainly does not cause it, and the presence of disease is not essential.—I am, etc.,

Liverpool, May 6th. JOHN HAY.

RHEUMATIC INFECTION IN CHILDREN.

SIR,—With all respect I venture to differ from Dr. Leslie Thorne Thorne (May 7th, p. 855) when he says that enforced school attendance is the cause of the greater incidence of rheumatic infection in children attending elementary as compared with those who are sent to private schools. Surely the fundamental reason for the difference is to be sought in home environment, and in many instances constant, or frequent, exposure to damp, due to bad housing conditions, bad boots, insufficient or unsuitable clothing, with frequently no second change when the child gets wet, are the lot of the elementary school child, and lead to "growing pains," slight sore throats, etc. For these conditions the school cannot be held responsible; and, indeed, a child suffering from a slight "chill" is often better in a well warmed, well ventilated classroom than at home, where the mother may be out at work, and where the child, in any case, will almost certainly not be kept in bed.—I am, etc.,

EVA MCCALL, M.D., Ch.B., D.P.H.

London, W.1, May 9th.

DAMP BUILDINGS.

SIR,—It is stated that an investigation is being carried out by the Royal Institute of British Architects into the causes and prevention of dampness in buildings, as a result of the report on rheumatism and rheumatic heart in children. Considerable stress was laid on this point of dampness in houses in the report. May I ask how the evidence of rooms and houses being damp was obtained? Was this evidence produced by authorities—the sanitary departments or other experts—or were the mere statements of patients and tenants accepted?

What constitutes a damp house or building? I have come across people who have declared their premises damp because warm vapour in a room has condensed on the cold walls, making them decidedly wet, but this can scarcely constitute a cause for a damp building.

Has any investigation been made in this connexion as to the incidence of rheumatic diathesis being inimical to *tuberculosis*?—I am, etc.,

Plymouth, May 7th. J. S. PEARSE.

MEDICAL DEFENCE.

SIR,—We are directed to request that you will kindly publish in your next issue the following statement with regard to the circumstances in which the council of either of the two English defence and/or protection societies may be prepared to advise and/or defend and/or indemnify a member.

Subject to the provisions of the Articles of Association the council may on application from a member who is in benefit—

1. Advise on any matter connected with medical practice.
2. Initiate or defend or assist in defending, proceedings where a question of professional principle is involved.
3. In the event of an adverse verdict, or of a settlement out of court, provide indemnity against damages and costs of the other side.
4. Defend or initiate and carry through proceedings to vindicate a member's *professional interests, honour, or character* whenever they have been threatened or jeopardized.
5. Defend and/or indemnify a member in proceedings brought against him in respect of the act or omission of:

(*a*) A partner who is a member of any other defence or protection society with whom a reciprocal *arrangement* has been entered into.

(*b*) An assistant who is a member of any other defence or protection society with whom a reciprocal arrangement has been entered into.

(*c*) An assistant not himself a member of any defence or protection society, provided that the member has paid an additional annual subscription of 10s.

(*d*) A locum tenens, whether a member of any defence and/or protection society or not.

(*e*) A subordinate medical officer, including a house-surgeon or similar hospital medical officer, whether a member of any defence and/or protection society or not.

(*f*) A non-medical assistant or subordinate, such as a nurse, dispenser, *x*-ray operator, massage or laboratory assistant, save in a case where in the opinion of the council such non-medical assistant or subordinate was with the sanction of the member, whether express or implied, carrying out (i) a duty which should only be undertaken by a medical practitioner, or (ii) without medical supervision a duty which should only be undertaken by a non-medical assistant or subordinate under the orders and direct supervision of a medical practitioner.

—We are, etc.,

HUGH WOODS, General Secretary, The London and Counties Medical Protection Society, Ltd.

JAMES NEAL, General Secretary, The Medical Defence Union, Ltd.

May 7th, 1927.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons has this week considered the Scottish Estimates and Ministry of Transport Estimates, and commenced the Committee stage of the Trades Disputes and Trade Unions Bill.

The Parliamentary Medical Committee met at the House of Commons on May 5th and arranged that Lord Dawson of Penn should, on May 19th, address an open meeting of members of Parliament on the case against the Dogs' Protection Bill, in reply to statements made in the House in support of that bill. Lord Dawson will also answer questions on the subject. In view of the recent appointment of a Select Committee on the registration of opticians, the Parliamentary Medical Committee decided to support the amendment which Sir George Berry and Dr. Vernon Davies had put down declaring that it was inadvisable to give a second reading to the Optical Practitioners' Registration Bill, which was the first order of the day on May 13th. The Committee also heard a statement from

ir Frank Colyer, who, on behalf of other medical men ractising dentistry, explained the circumstances in which he ad taken his name off the *Dental Register*. A discussion ollowed on this statement, but the Committee took no decision.

Experiments on Animals.

In the House of Lords, on May 4th, Lord Banbury opened discussion about experiments on animals by asking how many inspectors were appointed under the Cruelty to Animals Act, 1876. He said he made no accusation against the inspectors. He had no reason to doubt they were doing their duty properly and efficiently if that were within their power. The Home Secretary had said in the Commons that there were two whole-time inspectors who had last intervened on March 5th, 1926, to prevent an animal suffering prolonged and agonizing pain. Could Lord Desborough, who was to answer for the Government, justify the statement by professors and doctors that there never was cruelty, and that they could trust the inspectors to carry out the Act? Lord Banbury said that 242 places were licensed on April 11th for operations on animals, and quoted statistics of the number of operations performed in 1925. He calculated that each inspector would have to inspect 4,701 experiments yearly. Two men, however excellent, could not carry out these duties properly. Lord Desborough said that down to 1913 there were two part-time inspectors for Great Britain. In that year, after a Royal Commission, two whole-time inspectors were added. Sir James Russell, a part-time inspector, died, and the number was reduced to three, but the third, Sir George Thane, gave practically the whole of his time to the work. When Sir George retired, in May, 1922, the staff was reduced to two whole-time inspectors because of the need for economy in public expenditure. That need continued. The Home Office agreed that, for efficiency, three whole-time inspectors would not be too many, and four would be still better. The point of view of Lord Banbury, who suspected violation or evasion of the law, need not be taken into account. Licence holders did sometimes commit breaches of the Act or the conditions of their licences, but almost invariably through negligence or failure to understand an intricate and technical piece of legislation. Wilful evasion of the Act was practically unknown. The experience of the Home Office for many years had been that licence holders as a body were willing and anxious to comply with the letter and spirit of the Act, and to assist the Home Office in its administration. He was informed that more experiments were made at University College than at any other one place. In the last eighteen months its laboratories had been visited thirty times without notice by an inspector. Inspectors had a great deal more to do than to inspect; they had to be highly qualified persons, able to give advice when applied to by men and schools which wished to carry out some special piece of scientific work; and it would undoubtedly be a great benefit if the country could afford money for the purposes suggested. The Home Office, however, was not likely to approach the Treasury with the request. Lord Haldane said that the great bulk of the work done by the inspectors was paper work, scrutinizing the nature of the research proposed to be made and whether it involved pain. The inspectors did not run about, though they paid occasional visits to see that the conditions of the law were observed. Lord Haldane's view was that there was little violation of the Acts in this country. He was not sure that the Acts did not go too far. A few days previously a distinguished young physiologist had come to see him, and had explained that an experiment had to be made, and should be made on a dog. It was not serious, but could not be made under an anaesthetic. That physiologist said: "There is only one way for it, and I have come up to be vivisected," and he was vivisected. For several days he was in one of the hospitals, remaining in bed during part of the process. Lord Haldane said that some of the experiments stopped by the Act were experiments which human beings with a desire for knowledge were ready to undergo. He did not think it desirable that such experiments on men should be extended. Some of the provisions of the Acts went so far that, although processes were painless, they were hampered by the condition that anaesthetics must strictly be used, and that the animal must not be allowed to live. Lord Knutsford said the removal of a flea from one dog to another was an experiment under the Act. In all England and Wales only 267 places were licensed for vivisection, and 68 of these were in London. In the opinion of many people two whole-time men could do the work perfectly well. The irregularities last year were that one woman investigator immersed, without a licence, some trout in polluted water, and that another, holding certificate A, made simple inoculations into cats without authority. Lord Danesfort said he was not an antivivisectionist, but would be very sorry to see an extension of the powers given by the Act of 1876. The Royal Commission of 1912, having heard all the evidence from the scientific side, concluded that the existing inspectorship was insufficient. Unfortunately, the Commissioners' recommendation to have four full-time inspectors had not been carried out to the full. Lord Banbury said that the results to the animals concerned of breaches of the licence were just as bad if the mistakes were through ignorance. He trusted that economy would not prevent the Home Office from appointing more inspectors, and suggested that £3,000 a year would cover the cost. He withdrew his demand for papers, and the debate closed.

A Parish Medical Officer in Skye.—In an answer to Mr. Johnston, Sir John Gilmour said the special Commissioner appointed by the Scottish Board of Health had found that professional charges brought against the parish medical officer of Strath, Skye, had not been substantiated and ought never to have been made, and that there was no other ground on which his dismissal from the parish appointment would be justified. After consideration of the Commissioner's report, the Board had decided that this was a case which called for the protection afforded to parish medical officers in the Highlands and Islands by statute. Sir John concurred in this decision. In his question Mr. Johnston stated that the parish council of Strath had announced that it would resign unless given freedom to terminate the appointment.

After-effects of Lethargic Encephalitis.—On May 4th Mr. E. Brown asked whether the attention of the Home Secretary had been called to a case at the Central Criminal Court where a victim of encephalitis lethargica had been sent to prison with hard labour, although the judge had agreed that the prisoner required treatment, not as a criminal, but as an afflicted person. Sir William Joynson-Hicks said that after consideration he could not advise a remission of sentence. The young man was reported to have suffered from encephalitis lethargica in 1919, but was not now considered to be certifiable either under the Lunacy Acts or under the Mental Deficiency Act. All the relevant facts were before the judge when he decided to send the man to prison, where he was now under special mental observation in the prison hospital. Mr. Brown asked whether the Home Secretary did not think there should be an alternative in such cases. The Home Secretary said that was a matter for legislation by the House of Commons. Dr. Vernon Davies pointed out that the prisoner had been sentenced to nine months' imprisonment with such hard labour as he was capable of doing. He asked whether the Home Secretary would endeavour to hasten the passage of the Mental Deficiency Bill. In a later answer, on May 10th, Sir William Joynson-Hicks said the prisoner was 21 years old and therefore the question of committing him to the institution at Winchmore Hill under the control of the Ministry of Health did not arise.

Approved Societies and Massage and Electrical Treatment.—Answering Mr. Bowerman, Mr. Chamberlain said that if massage and electrical treatment were added to the list of additional benefits under the National Health Insurance Acts he would aid approved societies to secure for their members the necessary treatment under satisfactory conditions and on reasonable terms. Before making a regulation adding the treatment to additional benefits, he would have to be satisfied that a reasonable number of societies desired to amend their existing schemes.

Small-pox.—On May 9th Sir Kingsley Wood told Lieut.-Colonel Howard-Bury that twenty-seven deaths among persons suffering from small-pox had so far been reported in England and Wales during the present year. In some cases the death certificates had not yet been received. In reply to other questions, Sir Kingsley Wood stated that, in view of the danger of an epidemic, the Ministry is doing all it can to recommend vaccination, and is drawing the attention of school authorities to the matter.

Cost of Medical Inspection of Schools.—On May 9th Lord Eustace Percy, in reply to Dr. Vernon Davies, gave in tabulated form the number of school children examined by the medical officers of the Lancashire education authority for the last seven years. He said that in 1921-22 the estimated equivalent of whole-time officers engaged in school medical service work was 15.2, and the estimate of total salaries in respect of school medical service was £15,765. The number of inspections (routines, specials, and re-inspections) was 74,246. In 1926-27 the comparable figures were 13.6, £13,087, and 95,106. He could not state the average cost of medical services for each examination made, as the school doctor's work included many other duties connected with the school medical service besides medical inspection.

High Grade Certified Milk.—On May 10th, in reply to Brigadier-General Clifton Brown, who asked why producers of Grade A tuberculosis tested and certified milk were now to be brought under the further control imposed by the Milk and Dairies Order, 1926, Sir Kingsley Wood said producers of the higher grades of milk had always been subject to the statutory requirements applying to milk producers generally.

Baths at Spas.—The Minister of Health has not sanctioned the levying of a local rate for the upkeep of privately owned baths at any place other than Woodhall Spa, Lincolnshire. Any application in circumstances similar to those at Woodhall Spa would be considered.

Notes in Brief.

Three hundred first-aid dressings have been ordered for the use of the Metropolitan Police in the streets.

In 1926 there were 88,000 tons of machine-skimmed condensed milk imported into the United Kingdom.

Obituary.

ERNEST HENRY STARLING, C.M.G., M.D., F.R.S.,

Foulerton Research Professor of the Royal Society,
University College, London.

(With a reproduction of a recent photograph by Professor Raper of Manchester.)

LAST week we had with sorrow to announce the death on board ship, off Kingston, Jamaica, of Professor E. H. Starling at the age of 61. Of late years he had had indifferent health and had suffered from disabilities under which one of less heroic spirit could not have continued to work strenuously. His enthusiasm for the discovery of new truths was unimpaired, and his mind was so sympathetic and alert that it was difficult to believe he was not a sound man. Nevertheless, evidences of diminishing capacity for work without undue fatigue were obvious to his friends and a source of anxiety to them.

At the close of the winter session, during which he had been daily occupied with arduous experiments, he was very tired. The weather was cold and dull and he longed for sunshine and warmth. He therefore decided to take a voyage to the West Indies, in full hope that this would restore his energies and enable him to continue with enjoyment the experimental work with which he was occupied. However, that was not to be, but he had the satisfaction of going down with his flag flying, as he would surely have desired.

LIFE AND WORK.

BY

C. J. MARTIN, M.D., F.R.S.

Ernest Henry Starling was born in 1866. His father, H. H. Starling, was Clerk to the Crown, Bombay. The family of seven children had, perforce, to be educated in England. They therefore saw but little of their father and were brought up by their mother, a very extraordinary woman, and it is to her influence, by heredity and nurture, that Starling owed his determination, mental alertness, and much of his charm. As the eldest boy, in the absence of a father, he early acquired a sense of responsibility and capacity for managing his affairs, and was, in some respects, unusually mature for his years.

He was educated at King's College School. He left at 16½ years of age, having matriculated at the University of London with honours, and proceeded to the study of medicine. He chose Guy's Hospital because his uncle was a Guy's man.

At this time his ambition was to be a physician and live in Harley Street, and it was not until a few years later that he began to doubt the all-sufficiency of this ideal and to contemplate the possibility that he might be able to devote himself to an academic career and perhaps become a discoverer himself. As soon as he touched the study of natural science it was clear that Starling had found his *métier*. The causal relation of facts enthralled him. He was intensely curious and had a naturally scientific mind. He was gifted with fine intellectual machinery, a good memory, industry, and possessed of great powers for work, and it was soon clear to his teachers that they had a very exceptional pupil. The teachers of natural science at Guy's in those days were men of distinction, but they only called for a few hours weekly to deliver their lectures. The one who made a great impression upon Starling was Dr. Debus of the Royal Military Academy, Woolwich, who gave part of the lectures on chemistry. He was a fine teacher, and the enthusiasm with which he expounded the elements of chemistry was infectious.

At the examination in preliminary scientific subjects at the University, Starling obtained the first place in chemistry and botany, and second place in physics. He obtained so many medals and prizes as he proceeded through his medical course that an account of these academic victories at university and hospital would be wearisome. About two-thirds of the academic honours available were secured by him, including a free studentship at Guy's Hospital. These various college and university scholarships sufficed to maintain him, and if he had liquidated the many gold medals awarded to him he would have been able to enjoy comparative affluence.

Physics and chemistry attracted him and the generalization of biology, but it was when he came to study physiology that he met his fate. It cannot be said that his affection for physiology was due to his teaching at the hospital; it was largely his own discovery, but Foster's textbook made a great impression upon him.

After two years' study of physiology, during which he read many original papers, including all the back numbers of the *Journal of Physiology*, he had determined, I think, to become a physiologist, if such a career was economically possible. He had felt the deprivation due to his inadequate knowledge of German, so, after disposing of his second medical examination in 1886, he went, largely with the idea of improving his German, for a few months to Heidelberg, and worked in Kuhne's laboratory. He returned at the end of the year with his hair *en brosse*, much teutonized, and more than ever determined to become a physiologist. However, he had to put these aspirations aside for awhile and devote himself to the study of practical medicine. This he did with his usual enthusiasm. Starling found great satisfaction and enjoyment in clinical work. The human side appealed to his sympathetic nature and the immediate value of the application of knowledge to his practical mind. If it had been possible to devote himself whole-heartedly to the study of medicine, as is now possible by the institution of full-time professorships, Starling would have been as happy investigating disease as in a physiological laboratory. Indeed, not many years ago he seriously considered accepting such a position.

Having completed his medical studies and occupied the position of house-physician and house-surgeon at the hospital, Starling was confronted with the problem, how he was to live if he were to follow his desire and devote his life to physiology.

With his brilliant career at the hospital, the profession of a physician was open to him and success undoubted. He was keenly interested in medicine and pathology, and the temptation to follow the line of least resistance and greatest promise of reward was considerable. However, in 1889, he determined to try the rougher path and became demonstrator in physiology. The rewards of this office were minute, and Starling told me that he owed the possibility of giving his allegiance to science to a British Medical Association scholarship for medical research. The scholarship was worth £150 a year, and this addition to his slender salary kept him going. Next year, owing to the death of Wooldridge, a vacancy as joint lecturer on physiology occurred and Starling was appointed. On the termination of the British Medical Association scholarship he was appointed to the research scholarship of the Grocers' Company, of the value of £250 per annum. It was not then so easy to embark on a scientific career without financial resources as it is now, and it is terrible to think how one of Starling's glorious attainments was nearly deterred.

He was confronted, not only with the problem of how he was to continue to subsist on one-third of a salary which was never intended to command the whole services of a physiologist, but how he was to secure a physiological laboratory to work and teach in. The Grocers' scholarship temporarily solved the first problem, and he determined that adequate accommodation and equipment for teaching and research in physiology should ere long, by some means, be obtained. Meanwhile, being but one of three joint lecturers, he was able to arrange to go and work abroad occasionally. In 1893 he went to Breslau to work with Heidenhain, and later, for a few months, to the Pasteur Institute, as he was greatly impressed by Metchnikoff's discoveries about phagocytosis. In order that these might be more available to English students, he and his wife translated Metchnikoff's lectures on comparative inflammation.

ERNEST HENRY STARLING.

Until his hopes for a physiological laboratory should materialize, Starling did his best to secure some improvement of the arrangements for practical teaching and demonstration with the funds available; meanwhile he repaired to Schafer's laboratory at University College to carry on his researches. Bayliss was also working in the laboratory, and here began a scientific partnership which lasted on and off for thirty years. The two complemented one another in many respects. Whilst both possessed scientific imagination of the highest order, Starling was more ardent and forceful, eager to translate ideas into action, but rather bored with details of technical method. He had never been interested in doing things with his hands except climbing, although, later, he became a most beautiful and dexterous operator. Bayliss was the philosophical student, calm, with better critical judgement. He read widely and had a wonderful knowledge of scientific literature, was an excellent mechanic, and found enjoyment in the development of the technical methods of research. How fruitful this partnership was will be seen from the account below of Starling's scientific work.

The equipment at Guy's Hospital steadily improved, and he and Bayliss did their work on the innervation of the heart there. By 1895 Starling had planned a really good physiological institute for Guy's Hospital and had secured the assent of the authorities to its erection. These laboratories were completed in 1897, and were, at that time, the best laboratories for physiology in London. The amount of time and effort involved in this accomplishment was considerable. Unwilling authorities had to be persuaded to provide territory and funds, and colleagues to make sacrifices of their own legitimate aims, and although it was becoming recognized that Starling was going to be a great man and was an ornament to the staff, *this was no easy matter.*

Not long after the opening of the new physiological laboratories at Guy's Hospital the Jodrell Chair of Physiology at University College fell vacant owing to Schafer's acceptance of the professorship at Edinburgh. In 1899 Starling was appointed. It was a wrench to leave his fine new laboratories, to the construction of which he had devoted so much time, but the emoluments of the Jodrell Chair were greater, and the conditions at University College he deemed more favourable to the realization of his ideals. Moreover, he was determined that it should not be many years before he would have a new institute of physiology at University College, for the planning of which the Guy's laboratories would have served as useful exercise.

This determination came to fruition in 1909, when the present fine Institute of Physiology was *opened.* Starling's plan was not merely for a new physiological school, in which he was naturally more particularly interested, but he wanted all the medical sciences at University College to have the advantages of more commodious and nobler buildings. His original scheme was for an Institute of the Medical Sciences, including anatomy and pharmacology, as well as physiology, with a central library. At first only the physiological section was built, but a few years ago the erection of the whole institute, as originally contemplated, was rendered possible by a generous gift from the Rockefeller Foundation, which was desirous of devoting funds in the interest of medical science in London. That they chose this particular means of fulfilling their aims was largely, if not entirely, due to Starling, and the noble Institute of Medical Sciences with which University College is now endowed is a fine material monument to the memory of one who not only helped to build up a great school of physiology in London and obtained an appropriate habitation for it, but was as unsparing in his efforts to secure similar advantages for the other medical sciences.

In 1923 Starling retired from the Jodrell Chair and was appointed to a Foulerton Research Professorship of the Royal Society. He still continued to work at University College, but was relieved of all administrative duties and all teaching, except that of a small band of research pupils.

His laboratories continued to be a centre of great activity, and a limited number of distinguished young physiologists from this country and abroad still enjoyed the advantage of working in close communion with one of the greatest masters of experimental physiology. It was a happy family.

STARLING'S PHYSIOLOGICAL RESEARCHES.

"Only by following out the injunction of our great predecessor (Harvey), to search out and study the secrets of Nature by way of experiment, can we hope to attain to a comprehension of 'the wisdom of the body and the understanding of the heart,' and thereby to the mastery of disease and pain, which will enable us to relieve the burden of mankind." (Starling, Harveian Oration, Royal College of Physicians, 1923.)

Starling's interest in physiology was general, but the subjects for investigation which particularly attracted him were those physiological processes which seemed capable of interpretation in terms of chemistry and physics. Whilst realizing that adaptation was the essence of organism and had no counterpart in inanimate nature, he had not much sympathy with the neo-vitalists. In his view, if the contraction of muscle was not understood, it was because we did not know enough about physics and chemistry or about muscle.

He was always, from his student days, fascinated with the problem of the heart and the adjustment of its action to varying conditions of the body, and his first paper, written with Bayliss in 1891, was on the electromotive phenomenon of the mammalian heart. Waller had recently studied the electrical variation of the excised heart, and also of the heart *in situ*, by leading off from the neighbourhood of the apex and base respectively. It was evident to Starling that by photographing the movements of the capillary electrometer, connected with electrodes placed in different positions on the naked heart in the anaesthetized live animal, much might be learnt of the nature of the cardiac contraction; in fact, that a new method of observation was at the disposal of the investigator. At that time any sort of muscular continuity between the auricles and ventricles was denied, and the view that conductivity was due to some nervous network supplying the fibre was in favour. In this research he enjoyed the co-operation of Bayliss. They set out to ascertain the course and time relations of the wave of contraction in the ventricle, the nature of the transmission from auricle to ventricle and throughout the ventricle, and to examine critically Frédéricq's reasons for regarding the nature of the ventricular contraction to be tetanic.

They succeeded in showing (1) that the ventricular contraction is a single wave starting from the base, (2) that there is a natural block at the auriculo-ventricular groove, (3) that the rate of transmission of the contraction wave was about 5 metres per second. This sounds commonplace at this time when the electro-cardiograph is in general use for clinical diagnosis, but their observations not only formed an important step in the development of our knowledge of cardiac contraction and in the interpretation of disease of the heart, but, by showing what valuable information could be obtained by the electrical method, stimulated its employment and accelerated the development of the electro-cardiograph.

They next explored the separate action of the vagi and accelerator nerves on the auricles, on the ventricles, and on the conducting power of the auriculo-ventricular junction in the mammal. The effects of these nerves on the hearts of frogs and tortoises had been previously studied by Gaskell and Heidenhain, and that of the vagi upon the auricle of mammals. Bayliss and Starling completed the story, showing that there was no essential difference between the hearts of mammals and cold-blooded animals; that the vagus depresses conduction in auricle, auriculo-ventricular junction, and ventricle; and that the accelerator nerves had the opposite effects on all three structures. Two other important papers dealing with the mechanism of the circulation were published by Bayliss and Starling at this time. One was an exhaustive study of the simultaneous changes in the arterial and venous pressures of various regions of the body under a great variety of experimental conditions. The results showed the universal applicability of the principle of the circulation worked out by Ludwig. They said, in their paper, that the effects produced were such as might have been predicted by anyone with a knowledge of the elementary principles of the circulation. However, nobody had predicted

them. The last contribution of this first series of papers on the circulation was an analysis of simultaneous pressures in the aorta and ventricles of the heart *in situ*, by an ingenious method which was a vast improvement on any hitherto devised. They used a continuous photographic record of the changes in volume of a small air-space at the end of a capillary glass tube connected with the aorta and ventricle respectively. This method was free from inertia and aperiodic, and they succeeded in obtaining a true record of the rapid variations occurring in the ventricle and aorta, and the precise relation of these to one another. Their measurements have been the standard of reference ever since.

The Conditions Determining Transudation from the Vessels and Lymph Flow.

In 1892 Starling for a while relinquished the study of the blood circulation and turned his attention to the mechanism of lymph flow. The conditions determining the equilibrium between the liquids in the blood vessels and tissue spaces required exploration. Was lymph a transudation or an excretion? Heidenhain had recently published a stimulating paper on lymph formation, in which he concluded that, normally, filtration played no part in the formation of lymph, so, in 1892, Starling went to work in the Breslau laboratory.

Heidenhain had distinguished two kinds of lymphagogues, and under his inspiration Starling set to work to make a more detailed analysis of the effects of one of them—peptone. In summarizing his results he adopted the interpretation of Heidenhain that the experimental facts concerning lymph formation could not be explained by filtration and that it was necessary to suppose a selective activity of the vessel wall. However, on returning to this country, he continued to work energetically at the problem of lymph formation, and repeated all of Heidenhain's experiments. He was able to confirm his facts, but came to doubt the correctness of his interpretation. He searched for evidence of lymph-secretory nerves, but found that the nervous system could only influence lymph flow by altering vascular conditions. After years of experimenting he came to the conclusion that it was unnecessary to suppose a secretory activity of the endothelium, and that there was no experimental fact inconsistent with the view that lymph formation was a function of two factors—permeability of the vessel wall and intracapillary pressure. Nevertheless, there were a number of observations equally unintelligible on either hypothesis, and further work with Leathes and Tubby on the absorption of various solutions from the pleural cavities only emphasized that there was yet another factor concerned in determining whether fluid passed in or out of the capillaries.

In 1896 Starling discovered that the missing factor required to afford a complete interpretation of the phenomena was the osmotic pressure of the colloids to which the walls of the capillaries are relatively impermeable. It had hitherto been supposed that the osmotic pressures of proteins, being so insignificant compared to that of salts, they must be of no account in physiological processes. The reverse is indeed the case, because it is only to such that the membrane is impermeable.

He therefore set to work to measure the osmotic pressures of the proteins in serum and found them to be, though small, of the order of magnitude of the capillary pressure. The problem was solved. The hydrostatic pressure and the osmotic pressure supplied the balance of forces necessary to explain the experimental observations. These, together with altered permeability of the endothelium, are capable of supplying a reasonable interpretation of oedema and pleural effusion, and formed the subject of his Arris and Gale lectures to the College of Surgeons in 1926.

Starling's work on lymph formation occupied five years, and is of the best he did. After long-continued and difficult experimentation, combined with observation of the highest order of accuracy, this hitherto obscure, but fundamentally important, region of physiology was finally illuminated by his dexterous experimentation and triumphant imagination.

The Movements and Innervation of the Intestines.

When Bayliss and Starling undertook this study, the nerve supply to the small and large gut had been carefully determined by Langley and Anderson, but of the working of the neuromuscular mechanism there were many discrepancies as to fact and opinion.

After eighteen months' careful experimenting, with many appropriate recording methods devised for the purpose, they were able to reduce the previous chaos to order and to summarize the main facts concerning intestinal movements in a few simple statements. (1) That peristaltic contractions are true co-ordinate reflexes carried out by the local nervous mechanism and independent of the connexion with the central nervous system. (2) Local stimulation of the gut produces excitation above, inhibition below. (3) Besides the local mechanism, every part of the gut is subject to the control of the central nervous system through the splanchnics and vagi, the former being inhibitory and the latter containing both augmenting and inhibitory fibres. This was as far as understanding of the matter progressed until Cannon introduced the method of observation by means of x rays in an animal fed upon a bismuth meal.

The Mechanism whereby Pancreatic Secretion is Normally Evoked and Adjusted to Requirements.

The brilliant discoveries of Pavlov had determined the order of events in gastric secretion and their co-ordination through the agency of the nervous system, but although he had found that no secretion from the pancreas occurred until the acid chyme reached the duodenum, just how pancreatic secretion was called forth in an appropriate manner had baffled this great experimenter and his pupils. Popielski had determined that the introduction of acid into the upper part of the small intestine caused secretion from the pancreas, notwithstanding previous section of the vagi and sympathetic or even complete extirpation of the solar plexus. He concluded, therefore, that secretion must be brought about reflexly, by means of some local nervous apparatus.

Bayliss and Starling started their investigations with the idea of deciding where this peripheral nervous mechanism was. They verified all the facts stated by the Russian physiologists, but were unsuccessful in proving the existence of any nervous mechanism controlling pancreatic secretion. Nor could they discover how secretion was brought about until they made the crucial experiment which led to the discovery of secretin.

I happened to be present at their discovery. In an anaesthetized dog, a loop of jejunum was tied at both ends and the nerves supplying it dissected out and divided so that it was connected with the rest of the body only by its blood vessels. On the introduction of some weak HCl into the duodenum, secretion from the pancreas occurred and continued for some minutes. After this had subsided a few cubic centimetres of acid were introduced into the enervated loop of jejunum. To our surprise a similarly marked secretion was produced. I remember Starling saying: "Then it must be a chemical reflex." Rapidly cutting off a further piece of jejunum he rubbed its mucous membrane with sand in weak HCl, filtered, and injected it into the jugular vein of the animal. After a few moments the pancreas responded by a much greater secretion than had occurred before. It was a great afternoon.

Bayliss and Starling followed up their discovery in many important directions which space forbids me to mention. A method of obtaining natural pancreatic juice was now available, and they made full use of their opportunities to study trypsinogen and its conversion into trypsin by enterokinase. Their observations were subsequently summarized and their significance illustrated in their Croonian lecture to the Royal Society in 1904.

Starling was also moved by them to much constructive thought and further research on the chemical integration of the bodily functions generally. He proposed the name hormones or chemical messengers for all such active principles formed in one part of the body and distributed by the

rculation to excite the normal functioning or stimulation growth of other parts. This fascinating story, embellished with a wealth of illustration, formed the subject his stirring Croonian lectures to the Royal College of hysicians in 1905, entitled "The chemical correlation of ie functions of the body."

Movements and Adaptations of the Isolated Heart.

The behaviour of the heart had interested Starling from ie time he was a house-physician. His earliest work was pon the heart, and, though he diverged into other fields f investigation, the questions which intrigued him at that me always retained their fascination. In 1909 he returned gain to their investigation. He had been attempting to issociate the effects of asphyxia on the circulation into hose due to diminished oxygen and increased carbonic cid tension respectively. He used the "spinal animal" –that is, one in which the brain above the pons has been estroyed. He obtained some interesting information, but he observations were difficult to interpret until he should e able to separate the effects of alteration in the gaseous omposition of the blood upon the heart itself.

To arrive at this it was necessary to be able to record he influence of variations of CO_2 and O_2 upon the mammalian heart isolated from the nervous system and not ubjected to any simultaneous modification in its nutritive tate, in the inflow of blood, or in the amount of work it vas called upon to do. To satisfy these requirements the eart must be isolated from the rest of the body and at he same time must receive a constant supply of perfectly oxygenated blood, and be working under mechanical conditions completely under the control of the experimenter.

This was accomplished by a device, now famous, known as Starling's heart-lung preparation in which the lesser circulation is intact, but the only paths from the left ventricle to the right auricle are: (1) through the coronary arteries, (2) through an artificial connexion in which the resistance can be regulated. By *appropriate means* the pressure and flow in different parts of the circulation can be recorded and also the volume of the blood circulation per unit time and the *work done* by the heart. If required, the gaseous metabolism of the heart contracting under various conditions can be studied. The limited amount of blood in circulation permits analysis of its contents from time to time. Further, the method is admirably adapted to the observation of the direct effect of drugs, etc., upon the mammalian heart, working under every conceivable condition. Nor does this exhaust the possibilities of Starling's heart-lung preparation as an engine of research into cardiological problems. The flow through the coronary circulation can, if necessary, be diverted and measured so that change in the blood supply to the cardiac muscle can be determined.

After the perfection of this technique, a series of discoveries were made by Starling and his pupils which, in conjunction with those of Lewis, have made the laboratories of University College as famous a focus of research upon the circulation as was the laboratory of Carl Ludwig sixty years ago. The years immediately succeeding the development of this method of studying cardiology were the most productive, from the point of view of scientific output, in his career. He was surrounded by enthusiastic and devoted pupils drawn from all over the world. He had plenty of problems for them to attack, with every prospect of a reasonable reward for their efforts, and he was unsparing in helping them towards their solution, often performing the more difficult parts of the experiments himself and subsequently writing their papers for them.

It is only possible to indicate the principal researches undertaken and the more fundamental facts established by this happy band of discoverers until it was scattered by the outbreak of war in 1914. Detailed accounts will be found in the publications from his laboratory between the years 1910 and 1915. They are in no case merely qualitative observations but quantitative determinations. They occupy hundreds of pages of the *Journal of Physiology* and other journals during this period. They show the marvellous power of the heart, apart from the nervous system, to adapt its work in accordance with the needs of the body as a whole and the exquisite mechanisms to enable it to do this within wide limits, without embarrassment or permanent injury.

In the first case, the effects of variations in the tensions of O_2 and CO_2 in the blood upon the diastolic volume and output of the heart, on its capacity for work and on the flow through the coronary arteries, were determined. The heart was found to have an astounding power of utilizing the oxygen in the blood. When an isolated heart was fed with blood from an asphyxiated animal, the heart removed all but traces of oxygen.

The conditions controlling the rate of the heart beat were studied, and the only influences found to modify the rate of the isolated heart were temperature, the volume of the inflow, and adrenaline. The maximum output of the heart was measured and found to be 3 litres a minutes for a dog's heart weighing 50 grams. Important observations were also made upon the energetics of the heart by determining the O_2 used per unit of work done. The respiratory quotient of the normal and diabetic heart was ascertained, and from these two sets of observations the efficiency of the heart as a machine working under various loads was determined. The ventricular output was discovered to be independent of the arterial pressure, but, on the other hand, it was found to be dependent upon inflow. From this it appeared that as the heart dilated and its fibres were stretched, it worked with greater efficiency. This was subsequently shown to be the case by his distinguished pupil Lovatt Evans.

Their experiments upon the flow of blood through the coronary arteries showed that this flow was primarily dependent upon the arterial pressure, but that dilatation of the coronary system occurred when the CO_2 tension in the blood increased, when adrenaline was added, and most markedly when some metabolites, the product of the heart's own activity, were added to the blood circulating. In the latter circumstances the increased flow through the coronary arteries was out of all proportion to the pressure in the aorta, a further indication of automatic adjustment to a condition of stress.

Starling having supplied us with a new method of inquiry, many competent physiologists could have ascertained much of the information outlined above, but there was one discovery which is peculiarly the product of his genius—namely, that cardiac muscle, like voluntary, contracts more forcibly as it is stretched even up to the point when the texture is fractured. Therefore, to work at greatest efficiency a heart must first dilate, which it inevitably does, as the pressure in front of it increases. This is what Starling calls the "law of the heart." As he said in the fine Harveian oration he delivered before the College of Physicians in 1923, when he expounded in simple and beautiful language the results of his researches into the movements of the heart, "The heart has thus the power of automatically increasing the energy evolved at each contraction in proportion to the mechanical demands made upon it, behaving in this way almost like a sentient, intelligent creature."

Starling's Services during the War.

After war broke out Starling became very unsettled. He wanted to go into the fighting line. Persuaded, if not convinced, that this was not the most suitable manner in which to satisfy his strong tribal instincts, he joined the R.A.M.C. as a captain, and was for some time a medical officer at the Herbert Hospital.

Later, as the scientific resources of the country were mobilized, he was made director of research at Millbank, and was busy experimenting with defensive methods against poison gases. In this he rendered invaluable service to his country, and no one was better able to control a research laboratory. However, at the end of 1916 he was exalted to the rank of lieutenant-colonel and sent as chemical adviser to Salonica, where he had nothing to do. Maybe his impatience of official methods embarrassed the authorities. In 1917 he resigned his commission, deeming that he could be of greater service as a civilian.

At that time food shortage seemed most likely to decide the issue, and he became chairman of the Royal Society Food Committee, and was largely responsible for the value

of the advice given by it to the Government. Subsequently he was Scientific Adviser to the Ministry of Food, and British Scientific Delegate on the Inter-Allied Food Commission.

In all these capacities he rendered yeoman service. He soon had a mastery of the necessary facts, and he was by nature and training able to marshal them comprehensively and arrive at definite conclusions. He was never "havering," and he impressed all those statesmen and officials with whom he had to deal. It is doubtful whether any other of our physiologists could have served us so well.

LATER RESEARCHES ON THE CIRCULATION.

For awhile, after the war, Starling's work was seriously curtailed owing to ill health, which finally necessitated a serious surgical operation. However, in 1920 he was back again at work, with Anrep, on the central and reflex regulation of the circulation by an ingenious cross-circulation method, built up on his heart-lung preparation. In this method, the circulation through the brain of an animal is entirely under the control of the experimenter, while the animal's own heart supplies the rest of its body.

By this dexterous device they were enabled still more to unravel the complex mechanisms of the adjustments in the vascular system. A notable discovery was that, whereas rise of aortic pressure leads to dilatation of the blood vessels as long as the depressor nerves are intact, change in the blood pressure in the supply to the brain produces the reverse change in the pressure of the rest of the body. These fundamental laws of vasomotor regulation were suspected but never before established.

STUDIES ON THE SECRETION OF URINE BY THE ISOLATED KIDNEY.

The heart-lung preparation affords a means by which any isolated organ may be fed with arterial blood of known composition at any desired pressure, rate of flow, and temperature. It is thus possible to study the functions of an organ apart from nervous influences and from the chemical influences which may arise in consequence of modifications in the blood caused by other organs of the body. After numerous attempts Starling and Verney succeeded in maintaining the isolated kidney in such a condition that it would secrete abundant urine.

By this method, which demands extraordinary experimental skill, Starling has opened a new chapter on the physiology of renal secretion. Already many new facts, and others which were previously only matters of surmise, have been discovered and established. His observations with Verney, and in collaboration with Eichholz, have shown that the glomeruli filter from the blood plasma its non-protein constituents, and that by using hydrocyanic acid to suspend tubular activity, a pure glomerular filtrate is obtained from the ureter. Also, that whilst urea and sulphate are secreted by the tubule cells, water, chloride, bicarbonate, and glucose are reabsorbed by the tubule cells from the glomerular filtrate. Pituitrin increases the amount of chloride and decreases the amount of water eliminated.

The influence of the pituitary gland upon the secretion of the kidney was particularly studied by his pupils Eichholz and Bruhl. Their experiments suggest that the inability of the isolated kidney to secrete inorganic phosphate is due to the absence of the pituitary hormone. If this be so it is another discovery of a chemical correlation of the body for which Starling is largely responsible.

These researches on the isolated kidney were in full swing in April, when he left for the holiday which was long overdue. They were affording most important results, and doubtless, had he been spared to continue them, he would, with his unrivalled experimental skill, ultimately have succeeded in clarifying our knowledge of urinary secretion, as he discovered the principles involved in the self-adjustments of the heart to physiological requirements.

STARLING AS A TEACHER.

Starling was a fine teacher. He had not a natural gift of oratory, but, by practice, he early became a good, coherent, and agreeable speaker. He had a happy way of finding telling phrases to emphasize the main points of his discourse, and sometimes, when feeling deeply, he was eloquent. His enthusiasm was infectious, and his pupils enjoyed his lectures.

His influence as a teacher was, however, not confined to those who had the privilege of sitting at his feet. His *Principles of Human Physiology* is the best textbook on the subject in the English language, and is widely used by students on both sides of the Atlantic. It has also been translated into Spanish.

As a teacher to research students he was ideal. He loved the companionship of young men. To everyone, provided only that he were a serious inquirer after truth, he was ready to extend help, encouragement, and friendship.

An account of Starling's scientific career would be incomplete without allusion to the part played in it by his wife. In 1891 he married Florence Wooldridge, the daughter of Sir Edward Sieveking, M.D. They were inseparable companions. With unselfish devotion she helped him more than will ever be known. They discussed all his projects together, and for many years she performed for him all the functions of an efficient secretary. Further, in addition to the responsibilities of bringing up their four children, she bore on her shoulders the burden of the humdrum duties of his life, thus releasing the more energy for his work.

Starling was the recipient of many academic honours. Honorary degrees were conferred upon him by the Universities of Dublin, Sheffield, Cambridge, Breslau, and Heidelberg, and he was a foreign member of several learned societies. He received the Baly Medal in 1907 and the Royal Medal of the Royal Society in 1913.

What place amongst the great discoverers in medical science should be allotted to Starling must be left to the judgement of posterity, but it will be generally conceded by his contemporaries that he was one of the foremost physiologists of our time and that no one since Harvey has so greatly advanced our knowledge of the action of the heart.

Although no man gave more devoted service to science, his interests were many-sided. He loved music, he loved beauty, he loved a fight; in fact, he loved life. The great charm of his companionship was, in part, due to his extraordinary mental alertness and boyish enthusiasm; like Peter Pan, he refused to grow old. His death means a sad loss to all of us, and will be felt not least by the generations of pupils who have been his companions during his life-long search for new knowledge by experiment.

As mentioned above, Starling was awarded a research scholarship by the British Medical Association at a critical period of his career; the subject he undertook to investigate was "Intracardiac pressure and the origin of the secondary waves on the pulse curve and the causation of morbid changes in the pulse curve." In the previous year he had received a grant in aid of a research on the reaction of degeneration, but did not use it, having been associated with Bayliss in a research on the mode of contraction of the mammalian heart, for which the former had received a grant. A report of this research was published in the BRITISH MEDICAL JOURNAL of July 25th, 1891. It is interesting to note that this grant was intended to cover also an inquiry into the nervous supply of the pancreas, and its relation to diabetes. Starling was a member of the Scientific Grants Committee from 1902 to 1906, and afterwards acted as inspector for the Science Committee of the work of the research scholars and recipients of grants for the London district. He was a member of the Research and Laboratory Workers Subcommittee of the Science Committee from 1919 to 1921. He was secretary of the Section of Physiology at the Annual Meeting in London in 1895, and president of the same Section at the Annual Meeting in Sheffield in 1908.

A memorial service was held at St. James's, Piccadilly, on May 6th. Among those present were Sir Charles Sherrington, Sir J. H. Parsons, Dr. H. H. Dale, representing the Royal Society; Sir James Fowler, representing the trustees and Advisory Board of the Beit Fellowships; Sir John Rose Bradford, vice-chairman of University College; Dr. A. M. H. Gray, Dean of University College Hospital Medical School; Professor C. A. Lovatt Evans,

nt occupant of the Jodrell chair of physiology at y College; Professor J. Barcroft, representing the ge School of Physiology and the Chemical Welfare ce of the War Office, and Dr. C. J. Martin, of the Lister Institute. Many students from y College were present.

SOME TRIBUTES.

DWARD SHARPEY-SCHAFER, F.R.S., Professor of gy in the University of Edinburgh, has responded quest by sending us the following appreciation.

became acquainted with Ernest Starling when he University College to attend my advanced course ration for the physiology of the first M.B. of the ty of London, the facilities for such instruction at lospital—where he was studying physiology under lge—not having at that time become developed. It niversity College that he made the acquaintance of Bayliss, who was working in the laboratory at the l changes in secreting glands and on the depressor nd who subsequently joined Starling in a series of ations on the electro-physiology of the heart and on hanism of secretion, which culminated in the dis- of secretin and the promulgation of the doctrine ical messengers, which has done so much for the ment of modern physiology and has had so important ng upon clinical medicine. This investigation was ed at Guy's Hospital, where Starling had succeeded dge in the teaching of physiology.

everybody else I was struck from the first by inality and force of character, and when I trans- to Edinburgh in 1899 it seemed clear that there one so well qualified to occupy the position at University College. This, at any rate, was w taken by the Committee of the Senate to the selection of my successor was entrusted, soon appeared that no better selection could have ade. Starling was not only an enthusiastic worker inspiring teacher. His influence was felt at Univer- llege far beyond the range of his own subject. He occupied the chair many years before he succeeded ing a large enough sum of money to build the institute, which is well equipped for carrying on aching and research in all branches of physiology. ok the place of the old department, which occu- he upper floor of the north wing, and which elf succeeded a laboratory of three rooms—one n a cellar—which had been placed at the dis- my predecessor, Professor Burdon-Sanderson, when ceeded Michael Foster as professor of practical gy in 1870.

since I came to know Ernest Starling we have a close touch with one another, and no one could him without appreciating his energy, loyalty, and hy. Although British physiology has sustained s losses of late years by the death of William , Augustus Waller, Frederick Mott, and John t Langley, no loss will be more felt than that of Starling; and this feeling will not be confined to n countrymen, but will certainly be shared by our ues belonging to all other nations.

CHARLES SHERRINGTON, O.M., F.R.S., Waynflete sor of Physiology in the University of Oxford, has the following:

death of Professor Starling is a grievous loss to physiology. The debt which our science owes to systematically set forth in the full notice which s of him in this issue of the JOURNAL. But even the t references to it cannot fail to remark that in n to the splendid set of researches on the circulation he gave to his science he contributed also to its nd means for further inquiry, and other and future will benefit from the conspicuous labour he gave ls securing financial support for laboratory and nel. University College, London, especially can bear s to this part of his achievement. Indeed, a leading "*motif*" throughout Starling's life was his devotion to the progress of that college, with which for so long his activity was connected.

One of my earlier personal recollections of Starling goes back to a time when we both of us were teaching physiology in London, and on the arrival of the summer vacation took our holiday together climbing in Switzerland. His enthusiasm for the hills and mountains was immense, and he was a good "goer"; he made one of the most excellent and enjoyable of companions. At that time he spoke not rarely of a desire to make his career in experimental pathology. Medicine was certainly his source of inspiration then, and I think it always remained so.

The long and intimate association with Bayliss rises to mind as one of the most fruitful and attractive of scientific collaborations of their period. Part of its strength lay in the two men being in not a few ways of complemental quality one to the other. For instance, a resolute but placid enthusiasm of the one met a high-tension and impetuous enthusiasm of the other; and again, the one without, the other with, full formal medical training. And both reinforced each other's enthusiasm, for both had the power of strikingly transmitting their enthusiasm to others. Starling's death leaves a void which those who knew him realize best cannot be filled.

Dr. H. H. DALE, Secretary of the Royal Society and Head of the Department of Biochemistry at the National Research Institute, Hampstead, has answered our request for a tribute by sending us this glowing picture:

Physiologists all over the world will mourn the loss which Starling's untimely death brings to their science, and to many it will further mean the breaking of warm personal friendship. Here, in the British circle, where many had been his pupils and co-workers, and all had found in him a loyal and generous comrade and leader, it is impossible to think of physiology in the past thirty years without Starling as a central figure of inspiration. The advance of physiology was to him the thing of supreme importance in life, worthy of the utmost that he could give of his skill and of his overflowing energy of mind and body. The war, with its diversion of normal aims, seemed for a time to have done what no threat of exhaustion could achieve, and to have dimmed the fire of this great enthusiasm of his life. It soon flamed high again, though he was threatened by physical disaster such as, for most men, would have meant the end of all but a restrained activity. Starling's courage was indomitable; his energy and his passion for knowledge flouted all restraint. When in 1923 he accepted the newly founded Foulerton Research Professorship of the Royal Society, it was hoped that freedom from the burdens of formal teaching and administration would give him a full decade of quiet and unhampered work in his own field of research. He threw himself eagerly into a series of brilliantly conceived but exacting investigations. These four years of fruitful work, with a succession of able pupils and collaborators from this and other countries, gave him the old joy of achievement, but must have imposed an increasing physical strain, such as only his wonderful courage could ignore. To have worn himself out in the service of the science which he loved, and then to go quietly from the scene, was an end, one must think, not far from his own ideal. For those who remain it is difficult to think of a future lacking the stimulus of his intense vitality and generous enthusiasm.

To Professor J. B. LEATHES, F.R.S., Professor of Physiology in the University of Sheffield, we are indebted for the following striking tribute to Starling's qualities:

Starling's love for the science to which he devoted his life was such that he regarded all who were in its service as his friends. His death is a loss they all must feel, no less deeply for what it is to them personally than for the end thus set to the extraordinary fruitfulness of his devotion to physiology. Those who had the privilege of association with him from the early days of his career one and all know this. But it remained true to the end; he did not change. In any society of men it is rare indeed

for members to identify themselves so completely with it as Starling did with the Physiological Society. For more than thirty years he was at its heart as it always was at his. Among those who knew Starling as a teacher, even in the years before he was 30, there must be many who still feel the power of his enthusiasm. The vivid light that he could concentrate on facts meet for reflection made difficulties glow with meaning. When a teacher can make his pupils feel that his whole life and being reinforces his intellect in its assault on the obstacles to understanding, he will have followers. He had many, who will to the end draw much of their best inspiration from the memory of what he was to them in the days when it all came from him. This is his legacy to physiology. His companionship, exhilarating to look forward to, will now be always exhilarating to remember, like the sun and air in the high Alps, where it was best of all. There to see the way he set about the day's work was good, partly because it was the same as the way he set about an experiment—the same eagerness and zest, the same forethought and attention to detail. When he could take a holiday it was to the Alps that his thoughts turned; from whatever was irksome in a busy life it was in his experiments that he found relief.

We have received this tribute from Professor ELLIOT SMITH, F.R.S.; it is dated from the Institute of Anatomy, University College—a building under the same roof as the Institute of Physiology—and is most appropriate, for no one better than Starling appreciated the value of the close working together of anatomy and physiology:

Others have written with fuller knowledge and competence of Starling's vast influence in the progress of physiology, of his superb skill as an experimenter, and of his happy association with Bayliss in providing new and fruitful conceptions of the essential phenomena of living processes. Every field of investigation that he cultivated was enriched, not only by additions to our information, but also with new methods of study and stimulating suggestions. Starling was not one of those who devote themselves to a select band of followers. His influence was world-wide; and it was physiologists in general and not simply a group of disciples who enjoyed the fruits of his labours and the inspiration of his help and guidance. A quarter of a century ago Starling foresaw that with the increase of specialization and the development of new departments of knowledge there was a danger of the medical sciences becoming separated and so losing that intimate correlation which is essential for real progress. Hence he set to work to design a scheme which would keep all these sciences in close touch with one another and promote the integration of all by permitting readjustments of the boundaries of the different departments to meet new circumstances and provide better co-operation. He was largely responsible for collecting the money to erect his Institute of Physiology, and later, in extending this building, to make provision for pharmacology and biochemistry. These achievements were the chief factors in attracting the attention of the Rockefeller Foundation to University College. Their gift enabled the College to complete Starling's original scheme and to create an object lesson in co-operation between the medical sciences, which is already exercising an influence throughout the world.

Although Starling regarded physiology as the chief instrument in the search for truth, and was very frank and outspoken in expressing his opinions on other departments of biology and medicine, he was an easy man to work with and a delightful colleague. He was so honest and courageous that while he bluntly said what he really thought, he was ready to accept equal frankness from his colleagues without resentment. He was intensely loyal to the College to which he gave the best years of his life, and had a firm faith in the greatness of its destiny.

UNIVERSITY COLLEGE.

At a General Assembly of the staff and students of University College and University College Hospital on May 5th, the following resolution, moved by the Dean of the Faculty of Medical Sciences, Professor G. Elliot Smith, F.R.S., and seconded by the Dean of University College Hospital Medical School, Dr. A. M. H. Gray, was unanimously adopted:

That this assembly of the staff and students of University College and University College Hospital desire to express their sorrow and deep regret at the death of Professor Ernest Henry Starling, formerly Jodrell Professor of Physiology in the College.

In doing so they wish to record their high appreciation of his loyalty and devotion to the College, and of his conspicuous services to the advancement of knowledge and scientific method.

Among his many services they recall the high distinction he conferred upon the College by researches in many departments of physiology, which were not only important additions to our knowledge, but also bold adventures that stimulated research in the widest fields of biology, and provided new and fruitful conceptions of the essential phenomena of life. They recall also his great conception for the more intimate co-operation of teaching and research in all departments of the medical sciences, which, largely as a result of his own efforts, he was able to see realized in this College. But above all his enthusiasm in the search for truth, and his courage and honesty in giving frank expression to what he believed, conferred upon him a powerful influence in the College, which he always served with conspicuous loyalty and faith in the greatness of its destiny. He endeared himself to his colleagues and students by his boldness in doing what he thought was *right.*

This assembly desires to convey to Mrs. Starling and the members of his family their respectful sympathy in the great sorrow that has fallen upon them.

Universities and Colleges.

UNIVERSITY OF LONDON.

ACQUISITION OF THE BLOOMSBURY SITE.

THE University of London has been enabled to acquire the site in Bloomsbury to the north of the British Museum originally bought for it by the Government in 1920. It may, we think, be assumed that the decision is final, for the Duke of Bedford has agreed, and the Senate of the University was unanimous in accepting the offer.

The announcement was made by the President of the Board of Education at the Presentation Day dinner on May 11th in the following terms:

During the past few months, with the promise of a limited Government grant, the University of London has been negotiating with the Duke of Bedford and his trustees for the purchase for University purposes of part or the whole of what is known as the University site in Bloomsbury. These negotiations have now ended in agreement on essentials and, though the formal contract has still to be completed, it can be stated that the Duke has agreed to sell the whole site to the University, and that the University is in a position to buy it and has decided to do so. This purchase by the University has been made possible partly by the use of a limited grant promised to the University by the Chancellor of the Exchequer last July, and partly by a munificent contribution from the Rockefeller Foundation.

Lord Eustace Percy added that the announcement marked a great and historic moment in the history of the University of London, for the selection of its home was something more than a mere question of geography. The task now was to establish a university teaching centre worthy not only of the capital city of the United Kingdom, but of the capital of the Empire. The Vice-Chancellor, Sir William Beveridge, said that the choice of the site was now finally and fortunately settled. Although the formal contract was not complete, the site would pass very shortly into the possession of the University and would be irrevocably dedicated to University purposes; it would be the headquarters of the University and the spot from which its further growth would take place; it was in the heart of the capital city of London, and in the midst of the great teaching colleges in Bloomsbury. There were now in this district seven or eight colleges, forming a university larger than Cambridge, the next largest of the universities in the British Isles. They were grouped round the British Museum and the empty space north of the Museum which the University had now acquired. The University headquarters were still to make, and on this site of 8½ acres there would, he foresaw, presently be erected a central office, a senate house, a library, a ceremonial hall, examination halls, together with the Institute of Historical Research, a faculty club for teachers, a students' union, a centre for students' activities—and, above all, for hospitality to overseas students—headquarters for the O.T.C., perhaps two or more colleges, and, finally, the beginning of residential quarters, both for teachers and

students. At present the money in hand was only sufficient to build a central office, but as money became available it would be possible to erect on that open tree-bounded space something of beauty, to be a common possession and a common pride for all. A visitor to one of the ancient universities could not fail to feel how much of their influence was due to the sheer beauty with which they surrounded the young men and women that went to them. In London it could not be possible to do quite the same, but there could be built on the site something as unique and characteristic of London and the new arts and materials of modern building as the buildings of the old universities were characteristic of their time. He hoped that the University would have the means to seek and the luck to find an inspired artist who could embody the ideal in stone and glass. It ought to be possible to bring into the heart of London a group of buildings which, with their towers and spires rising to the sky, would form a shrine of youth and learning in Bloomsbury to rank with the shrine of our history and our liberties by the Thames at Westminster.

The site covers 11½ acres, including roads; it is bounded on the south side by the British Museum, on the west by Malet Street, where the Imperial College of Hygiene and Tropical Medicine is being built; on the north by Gordon Square, and on the east by Woburn Square, Upper Montague Street, and Russell Square; it is almost within sight of the House of the British Medical Association.

Presentation Day.

The annual presentation of degrees took place on May 4 in the Albert Hall, South Kensington; 2,700 degrees were conferred, and in addition 550 diplomas, certificates, and prizes were awarded.

Annual Report of the Principal Officer.

Dr. Franklin Sibly, D.Sc., who has succeeded Sir Cooper Perry as principal officer of the University of London, states in his report on the work of the University during 1926-27 that admissions by all channels numbered 7,663, as compared with 7,407 in the previous year, and 3,852 in the last year before the matriculation examination. There were 3,967 candidates for degrees, as compared with 3,819 in 1925; the number who took degrees and diplomas was 3,173, as compared with 2,908 in 1925. The roll of internal students now comprises 9,342 there were 9,323 in the year under review. The London County Council has made a non-recurring grant of £600 in any one year, and a capital grant of £1,000 for the current triennium to £57,933; it has undertaken to meet any demands arising during the year for the provision of University extension courses in institutes up to a limit of expenditure of £15,000 to Bedford College. An application for capital grants were made by the University generally, and a capital grant of £1,000 for engineering building; other applications for capital grants were considered at a second donation of £10,000 for engineering operation. A second donation of £10,000 for engineering University College was made by Lord Cowdray before sums have been received to endow a Queen Alexandra Danish and the Crown Princess Louise lectureship in reference is made also to the gift by Lady Godlee of University College and its medical school for the establishture in memory of the late Sir Rickman Godlee. An of £10,000 has been received towards the establishair of dietetics, and £180,000 has been presented by of the Laura Spelman Rockefeller Memorial to the of Economics for general endowment and capital

Hospital has been admitted as a school of the a period of three years. The visitation of schools is being continued, and during the year reports were received with regard to University College, King's College for Women, Household and Social ment, and East London College. It is stated that prepared to consider any scheme for co-operation colleges and the University.

his report Dr. T. Franklin Sibly refers to the of the year now commencing. The problem of a dignified home for the University has been and is, he thinks, approaching complete solution.

LEGE OF PHYSICIANS OF EDINBURGH.

eeting of the Royal College of Physicians of held on May 3rd, when Dr. G. M. Robertson, the chair.

rt Lord, C.B.E., and Dr. William Bell were ook their seats as Fellows of the College. Dr. Chambers was elected a Fellow of the College. were elected members of the College: Arthur hittingham, Ram S. Gupta, James Davidson, on, William L. Kinnear, and Raymond L. A.

Dr. R. A. Fleming was nominated a representative on the Conjoint Committee of Management of the Triple Qualification.

The Parkin prize was awarded to Dr. John D. Comrie.

The Freeland Barbour Fellowship was awarded to Dr. Thomas R. R. Todd.

The Services.

ROYAL ARMY MEDICAL CORPS WAR MEMORIAL.

THE service of dedication of the stained glass window, which completes the Royal Army Medical Corps War Memorial in Westminster Abbey, will take place on Sunday, May 22nd, at 4.15 p.m., in the Nave. Tickets of admission are not required for the service, but subscribers to the Memorial Fund and others interested desiring reserved seats for the 3 o'clock evensong preceding it should apply by letter to Major-General H. B. Fawcus, C.M.G., D.S.O., Room 313, War Office, Whitehall, S.W.1. Uniform need not be worn at the service of dedication.

Medical News.

THE next session of the General Medical Council will begin on Tuesday, May 24th; the President, Sir Donald MacAlister, Bt., K.C.B., M.D., will give an address at 2 p.m.

A MEETING of the Maternity and Child Welfare Group of the Society of Medical Officers of Health will be held at the Shoreditch Model Welfare Centre, 210, Kingsland Road, on Wednesday, May 18th, at 4.30 p.m., when cases will be shown by the medical officers of the Shoreditch Maternity and Child Welfare Department, and when a paper entitled "The Newcastle-upon-Tyne caloric percentage method of dieting the premature and the sick infant" will be read by Dr. Glen Davison at 5.45 p.m. The centre is passed by buses Nos. 22, 35, and 69 from Liverpool Street.

AT a sessional meeting of the Royal Sanitary Institute to be held at the Guildhall, Bath, on Friday, May 20th, at 7.30 p.m., a discussion on cremation will be opened by Mr. H. T. Herring, M.B., B.S., honorary secretary of the Cremation Society of England, and continued by Dr. Preston King, chairman of the Bath Health Committee. On the morning of the following day (Saturday, May 21st), after a paper on sewage disposal by Mr. E. P. Sissons, engineer of Bath, a visit will be paid to the Bath City Sewage Disposal Works.

A DISCUSSION on swimming baths will take place at a meeting of the Medical Officers of Schools Association at the house of the Medical Society of London (11, Chandos Street, Cavendish Square, W.1) on Friday, May 20th, at 5 p.m. The discussion will be opened by Dr. F. Graham Forbes, Divisional Medical Officer, Public Health Department, London County Council, Dr. F. W. Alexander, late medical officer of health for Poplar, and Mr. F. E. Wilkinson, engineer and surveyor, Willesden Urban District Council.

THE bi-annual dinner of the Aberdeen University Club, London, is to be held on Thursday, May 26th, at the Piccadilly Hotel, at 7.30 p.m. The Lord Rector, Viscount Cecil of Chelwood, will be in the chair, and the guest of honour will be Mr. John Buchan, LL.D., M.P. Any Aberdeen University graduates, past or present, men or women, wishing to join the club or attend the dinner are asked to communicate with Dr. Anstruther Milligan, 11, Upper Brook Street, W.1.

THE annual medical missionary breakfast of the Medical Prayer Union will be held on Wednesday, May 18th, at the Refectory, University College, Gower Street, W.C.1, at 8 a.m., under the presidency of Dame Mary Scharlieb, D.B.E., M.D., M.S. An address will be given by Dr. Katherine Harbord of Jaunpur, India. An intimation of intention to be present will be welcomed by the honorary secretary, Dr. Tom Jays, Livingstone College, Leyton, E.10.

MR. WALTER G. SPENCER has been elected to the Senate of the University of London.

THE annual Nettleship prize has this year been awarded by the Ophthalmological Society of the United Kingdom to Mr. Charles H. Usher, M.B., B.Ch.Camb., F.R.C.S.Edin., ophthalmic surgeon to the Royal Infirmary, Aberdeen.

THE practice of the National Hospital for Diseases of the Heart is now open to students who have completed four years of medical study, and short courses of instruction in cardiology will be held immediately preceding the final examinations. Particulars may be obtained from the Secretary of the Hospital, Westmoreland Street, London, W.1.

THE trustees of the Carnegie Hero Fund have awarded an annual grant of £120 to Dr. G. C. W. Williams, who was engaged in *x*-ray treatment from 1895 to 1926. Dr. Williams contracted dermatitis as a result of his work, and after eight operations, which included the amputation of the right hand and the loss of two fingers of the left, has been rendered almost helpless.

THE Fellowship of Medicine announces that demonstrations will be given by Dr. B. T. Parsons-Smith at the National Hospital for Diseases of the Heart, on May 17th, at 10 a.m.; by Mr. Maurice Whiting, at the Royal London Ophthalmic Hospital, on May 19th, at 1 p.m.; by Mr. Maynard Smith, at St. Mary's Hospital, on May 20th, at 2 p.m. These demonstrations are free to medical practitioners. From May 16th to 28th a special course will be held at the Infants Hospital, and there will be a late afternoon course at the Hampstead General Hospital for two weeks from May 16th. A ten weeks' course in neurology began on May 9th at the National Hospital, Queen Square. The Fellowship of Medicine can arrange for practical courses in anaesthetics and obstetrics, and for clinical assistantships in gynaecology. During June special courses will be held in diseases of the chest at the Victoria Park Hospital, in diseases of children at the Children's Clinic, in gynaecology at the Chelsea Hospital, and in ophthalmology at the Central London Ophthalmic Hospital. The Fellowship provides also a general course of instruction at the associated hospitals. Copies of all syllabuses and of the *Post-Graduate Medical Journal* may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

A SERIES of lectures and counter-lectures in aid of King Edward's Hospital Fund for London is being held during May and June in the Great Hall of the London School of Economics, Houghton Street, Aldwych, on Tuesdays, at 5.30 p.m. Tickets may be obtained from the British Charities Association, 103, Kingsway, W.C.2. The subjects are varied, but their irresponsible character may be gathered if we mention that the last debate of the series, on Tuesday, June 21st, will be between Mr. G. K. Chesterton and Mr. Mitchell Banks, K.C., M.P., with Miss Rose Macaulay in the chair, the subject being "Is the House of Commons any use?"

A COURSE of four consecutive week-end demonstrations will be given at St. Bartholomew's Hospital during June and July, commencing at 5 p.m., on Friday afternoons, and terminating on Saturday evenings. On June 17th and 18th the subject will be modern methods in the diagnosis and treatment of chronic diseases of the lungs, and the following week-end will be devoted to the treatment of the common fractures of general practice. The diagnosis and treatment of chronic renal disease will be considered on July 1st and 2nd, and ante-natal methods will be dealt with on July 8th and 9th. The fee for each week-end is one guinea, or four guineas for the course. Further information may be obtained from the Dean, St. Bartholomew's Hospital, E.C.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

A BRITISH medical man, aged 62, resident abroad, has a blood pressure of 170 to 200, and suffers from daily attacks of pain, beginning over the centre of the sternum, spreading to both sides of the neck and head, and down both arms. It is worse after food or any little excitement. He asks for advice.

FACIAL SPASM IN A CHILD.

"A. G." asks for suggestions in regard to treatment and prognosis in the following case: A boy, aged 5 years, has developed a facial habit-spasm. He frequently draws up his nose and winks the eye at the same time on the side affected. Adenoids were removed some time ago, and his teeth were damaged at the time of the operation. He has been troubled with enuresis, which is practically cured. Otherwise he is healthy and is very quick at learning.

ASPIRIN AND POTASSIUM CITRATE.

DR. BRODRIBB (Penmaenmawr), having observed that aspirin dissolves freely when prescribed together with potassium citrate, inquires whether the dissolution implies a chemical change in the drug and consequent modification of its therapeutic value.

*** The solution of aspirin by potassium citrate is unaccompanied by any chemical reaction, and there is accordingly no change in the nature of its physiological action. But although its chemical identity is preserved, there may be a notable difference in the therapeutic effects, for apart from the independent action of the potassium citrate, the speed and even the locus of absorption may be altered. It is said that aspirin passes through the stomach unchanged, but is slowly decomposed by the alkali of the duodenum, with liberation of salicylic acid. It would accordingly seem that its dissolution in potassium citrate would result in a larger absorption by the stomach and less being carried forward to the duodenum.

INCOME TAX.

Partnership Assessments.

A and B were equal partners in a practice until June 1st, 1926, when A's share was transferred to C. In whose names should the returns be made and how should the assessment be divided?

*** The return should be made by "A and B and successors B and C." In dividing the liability it should be borne in mind that it is the *gross* assessment—that is, the amount assessed before any personal allowances are deducted—that serves as the basis of the division. The shares of the gross assessment attributable to each partner will be as follows—A ½, B ½, and C ⅓; from these shares the full amount of the personal allowances due to each partner should be deducted. Thus if the amount of the assessable earnings less professional expenses is £3,200, A will be liable to tax on £400 less the £225 personal allowance and any others to which he may be entitled.

LETTERS, NOTES, ETC.

VITAL-STATISTICAL FACTS NOT GENERALLY RECOGNIZED.

DR. B. DUNLOP (London, S.W.) writes: It is stated in your issue of May 7th (p. 850) that "although some seventy thousand more babies were born in France than in England and Wales in 1926, the excess is reduced to little more than [illegible] thousand if account is taken of the higher rate of [illegible] Channel." The French rate was [illegible] 765,226 *minus* $\frac{1}{33}$ of 766,226 exceeds 694,897 *minus* $\frac{1}{33}$ of 694,897 by more than twice "twenty-six thousand." The slip or misprint is unfortunate, because people should know that the French death rate is only slightly excessive among the infants, but is slightly excessive also among the rest of the population. This suggests that the population is still pressing on its food supply and that there will be no further decline of the birth rate.

EARLY PARENTHOOD.

DR. A. R. RENDLE (Godalming) writes: Docteur Cabanès, in his book *Le sixième Sens*, quotes the case of childbirth in a girl aged 13, of another case in which the mother was aged 12, and of another case, occurring in Paris in 1756, in which the mother was 9½ years old.

FOREIGN BODY IN RECTUM.

"R. B. G." writes: I can add a third case to the two recent notes. An old friend (of my college days), who sent for me while on a visit to the neighbourhood many years ago, complained of a constant desire to defaecate, with slight melaena. On examination I felt a hard, longish, thin substance lying across the exit, which, on removal, not without difficulty and pain, turned out to be a codfish bone. On informing him he said that he had partaken of a fish supper two nights previously.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 42, 43, 46, and 47 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 44 and 45.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement at page 203.*

An Address on BIOLOGY AND MEDICINE.*

BY

J. S. HALDANE, M.D., F.R.S.,

OXFORD.

THE aim of Medicine is the maintenance or restoration of that we call health. It is thus our conception of what ealth means that is at the root of our conception of edicine. We recognize that health is a normal condition ich tends to be maintained apart from any conscious ort to maintain it. Health is just the normal uncon- us life of an individual, and knowledge of what, in ail, this normal life and departures from it consist in hus essential when by conscious effort, as in practical icine, we seek to safeguard or restore health.

The Distinctive Features of Life.

e phenomena observed in connexion with life are so ent from those observed in what we call inorganic e that we give the name Biology to the science or of sciences dealing with unconscious life, and we uish Biology from the Physical Sciences, which deal he inorganic aspect of Nature. Let us consider is difference consists in.

living organism we find structure, arrangement of nd movements of them, just as in phenomena which prot as inorganic. But in the case of life the , including its mass and composition, is actively ed or developed in the particular manner which al," and the activity of the structure is of such that the normal structure is maintained or Normal structure and normal activity are thus rmal or specific. If, moreover, we consider the e: the structure is alive, and alive in a manner ctions between an organism and its environment these reactions are so co-ordinated or directed d this co-ordination is what we call organic inorganic phenomena, on the other hand, we no co-ordination of activity with structure. uctures hold together, it is true; but their not regarded as being so directed that the maintained. This is what we mean when norganic structures and activities have no ificance, while organic activities have. The red for the moment in an inorganic sub- ture seems to us to be a mere matter of this reason can be described as chaotic, eferred to in the sequel.

ena of life, therefore, there is an element ot observe in connexion with inorganic is specific co-ordination in the relation and activity. Details of both structure the manifestation of something which velops itself in a specific manner as a hing is what we denominate and easily nd the science of Biology is the science ns of life.

of an organism we can also recognize not, in much or most of their detail, from inorganic phenomena. Thus we ng body what seem to be ordinary gases, behaving in every way like ids, or gases, except that a greater rganic co-ordination or control is , volume, and composition, and in hey exercise on the organism. In ntrol we interpret their presence as normal" limits. In the environ- r is present to what at first sight extent, and the physical sciences ho organic control shown in the organism and environment. By d reaction are referred to as

ester Medical Society, April, 1927.

stimulus and response, and in the relation between stimulus and response—for instance, in responses to stimuli by light —characteristic biological co-ordination or control is evident, while definite physical or chemical connexion between stimulus and response cannot be traced. This control is, moreover, the distinguishing feature for Biology. Hence organic co-ordination, though no account is taken of it by the physical sciences, does not cease when we pass outside the bodies of living organisms, but extends indefinitely into their environment, since the characteristic mutual relations between organism and environment are those of stimulus and response. The relationship, for instance, between Sirius and a photographic plate which receives its spectrum is different from that between Sirius and an organism which responds to its presence. To take another instance, the relationship between stimulus and response in so-called "reflex action" is different from that between physical cause and effect, as modern investigations of reflex action are progressively showing. In other words, the conception of life applies over the environment no less than over the bodies of organisms. Between life and its environment there is no line of demarcation; and even when we attempt to draw a definite line of demarcation between living structure and its environment we never succeed. Living structure and the "plasma" which we endeavour to picture as surrounding it melt into one another.

Thus the distinctive science of Biology is not a science which applies merely to the living bodies of organisms. It represents the interpretation of one aspect of what we observe, not merely in the living bodies of organisms, but also in what surrounds them. Biological interpretation, is, in fact, a method of interpreting part of our perceived experience, just as is physical interpretation and physical interpretation between biological interpretation over the whole tion is a logical difference. If we ask what necessity there is for extending biological interpretation over the whole of our perceived experience, the answer is that we can distinguish the same co-ordination between specific structure and activity in the relations between organism and environment as in the relations between the parts of an organism, so that organic wholeness is just as manifest in the relations between organism and environment as in the relations between the parts of an organism. From its very nature ordinary physical interpretation cannot express this wholeness, since structure and activity are regarded as independent of one another.

The Hippocratic Conception of Life as a Struggle in Nature against Chaos.

It is evident that we can see far more in both organism and environment than what we can describe in terms of life. We have to content ourselves with physical interpretation of these phenomena. Life, with its essential co-ordination, therefore appears to us as a constant, and under normal conditions successful, struggle with the essential chaos of what we interpret as a physical and chemical world, both within the body and in the environment. It is in this struggle that life manifests itself; and practical Medicine is simply the help we can give by conscious interference in the natural struggle for normal life or health. Were it not for the actual existence of this struggle therapeutic Medicine or Surgery would be helpless in face of the endless delicacy of living structure and its normal activities. We cannot repair the living body as we repair a machine: we can only assist the natural process of repair. Similarly, in preventive Medicine we can do no more than see that the struggle is not too hard for Nature to succeed in it.

The struggle of life is a natural phenomenon. We do not interpret it as conscious behaviour, but as a blind or unconscious manifestation of Nature. Another conception is needed for the interpretation of conscious behaviour. The fact that in studying life it is simply Nature that we are studying, and that it is the nature of life to maintain, restore, and reproduce itself, was first pointed out clearly by Hippocrates, who at the same time objected to the intrusion into medical theory of philosophical atomism, the early Greek form of the modern physico-chemical interpretation which reached its full development during

last century. The word Physiology, derived from φύσις, nature, and taking us back to the Hippocratic conception, is a reminder that in studying life we are simply studying a natural phenomenon.

Physiology, Anatomy, and Biochemistry.

In modern times the word Biology has been substituted for the word Physiology, to indicate the whole science of life, while Physiology is regarded as dealing solely with the activities of life, and is distinguished from Anatomy or Morphology, which deals with the structure of organisms, and Biochemistry, which deals with their chemistry. In so far as we make sharp distinctions of this kind we are losing sight of the essential unity of biological phenomena. Normal structure and chemical composition are only the expression of normal activity; and apart from the structure and composition which are the expression of normal activity, this activity is without biological significance. Whatever methods of investigation we may mainly be employing, it is active life itself that we are studying, since we cannot separate living structure and composition from living activity. It is impossible for investigators to be experts in every method of investigation, or be familiar with all forms of life. Hence it is necessary to divide biological investigation into different branches. But if, in doing so, we forget that every branch of biology is concerned with the essential wholeness of the phenomena of life for each individual organism, the result can only be confusion, since we lose ourselves in endless unconnected matters of detail. Functional significance is what biology is always searching for, and its discovery is for a biologist the understanding or power of predicting phenomena. Explanation in biology is simply the demonstration that a detail of structure or activity expresses the organic wholeness of life.

The Vitalistic and Mechanistic Theories of Life.

The view just presented is essentially the Hippocratic view of biology and Medicine, but is not the view which is at present commonly regarded as orthodox in the teaching of physiology and anatomy, and which is to a considerable extent reflected in the teaching of Medicine. If we go back to the commonly accepted biological conceptions of the early part of last century we find that instead of regarding the distinctive feature of life as corresponding to a conception applying to the whole of the relations between organism and environment, biologists generally believed that the behaviour of the whole environment and much of what is observed within the living body can be interpreted as nothing but physico-chemical behaviour, and that only within the intimate structure of the living body does such interference occur as to impart to the behaviour of living organisms its distinctive character. The interfering influence was called the "vital principle" or "vital force," and the corresponding general biological conception was known as vitalism.

The middle of last century saw a general uprising against vitalism, and a determined attempt to substitute for vitalism the conception that biology is simply one part, though a difficult one, of ordinary physical science. There can be no doubt that this attempt has not brought us, in appearance, any nearer to a physico-chemical conception of life. The distinctive features, already referred to, which stand out now far more clearly and in far greater detail than they did at the middle of last century. This is the result of detailed investigation by ever-improving physical and chemical methods. When the results obtained by these methods are put together, what they reveal is not mere physical and chemical mechanism, but the distinctive and specific co-ordination of structure and activity which is characteristic of life. With every experimental advance this co-ordination appears in greater and greater detail, and the assumed mechanism of life recedes further and further into the background.

To see this we have only to compare our present knowledge of nutrition, secretion, circulation, respiration, nervous activity, cell structure, or hereditary transmission with the knowledge of the middle of last century. There is, it is true, a popular and singularly confused idea that because the increased knowledge has been obtained with the help of physical and chemical methods the interpretation of the results must also be physical and chemical interpretation. The actual interpretation is, however, obtained, not from isolated observations, but from putting together a mass of physical and chemical data, and noting the co-ordination of structure, chemical composition, and activity. As isolated physical and chemical facts these data are unconnected and unintelligible; but they become logically coherent, and therefore intelligible or predictable, when they are interpreted as phenomena of life; in other words, as functionally significant—as manifestations of the struggle for normal life.

Vitalism gave apparent recognition to the characteristic co-ordination in the phenomena of life; but though vitalism is not dead there is no general tendency among biologists to return to it. In present-day theoretical Medicine this position is to a large extent reflected. In the actual practice of Medicine, however, the characteristic co-ordination between structure and activity—the so-called *vis medicatrix naturae*—becomes such a prominent feature that in the absence of a more adequate conception many, if not most, medical men are, I think, still at heart vitalists.

Why is it that biologists cannot return to vitalism? Instead of regarding the conception of life as a conception which applies to the environment as well as to the intimate structure of living organisms, the vitalists applied it only to the intimate structure, and accepted the idea that outside the intimate structure there is nothing but the essential chaos which, as already pointed out, appears to exist in the environment as interpreted on Newtonian lines by the physical sciences. Only inside the living structure is, according to vitalism, this chaos guided into biological order by the influence of the vital principle. Now it is easy to prove by actual experiment that all which the vitalists attributed to the interference of the vital principle within the body is dependent on conditions in the environment, or consists in responses to conditions in the environment. To deny this would not merely be to deny evident facts, but would tend to fetter or discourage experimental research. Vitalism is not the Hippocratic conception of life which I tried to place before you, and which embraces the environment in the conception of life. Whether from the standpoint of this latter conception or from that of experimental biology, vitalism is totally unsatisfactory; and in so far as the mechanistic movement among biologists was a throwing off of the shackles of vitalism I think it was a great step forward.

I have sometimes been called a neo-vitalist. Let me assure you that I am neither a neo-vitalist nor a paleo-vitalist. On the other hand, I am quite unable to accept the conception that biology can be regarded as a branch of ordinary physics and chemistry. My reason is that, as already pointed out, we find, as a matter of fact, that in the phenomena of life there is inseparable co-ordination of structure and activity, in such a way that the specific structure of each centre of life is maintained through its activity, and the activity is of such a nature as to maintain the structure. This fundamental fact distinguishes biology from the physical sciences, or at any rate from the physical sciences as interpreted on ordinary Newtonian lines, since structure and activity in the physically interpreted world are not regarded as connected with one another to form a specific and persistent whole. To make biological phenomena intelligible or predictable the distinctive conception of life is essential. If a label were required for this teaching one might call it neo-Hippocratism.

The Logical Separation of Biology from the Physical Sciences.

Biology is distinct from the physical sciences. It is an independent science with a fundamental conception of its own. The distinction is not one which, as the vitalists thought, we can localize in space within the organism. Nor can we, by tracing the course of evolution backwards, localize it in time. The theory of organic evolution requires the assumption of specific hereditary transmission, and hereditary transmission itself assumes the distinctive character of life. The idea that by a process of natural

selection life could be evolved out of, or "emerge" out of, physico-chemical mechanism is not a coherent idea. The distinction between biological and physical phenomena is a logical distinction, or a distinction in the general conception which we must employ in order to represent the distinctive character of the phenomena observed and be able to predict them. When we are considering what we call inorganic phenomena we deliberately neglect the biological aspect of our actual observations, setting this aspect aside as belonging only to what Locke quite inadequately designated as the "secondary qualities" of objects. But when we are considering living organisms themselves, or their environment in so far as it influences them, the biological aspect becomes of overwhelming importance, so that a biologist cannot neglect it without rendering his observations unintelligible as well as disconnected. The existence of biology is an assertion of the fundamental fact that Nature is no mere physical chaos.

The physico-chemical or mechanistic conception of life was doomed from its outset to failure. It attributed the characteristic behaviour of living organisms in regulating the influence on them of environment to peculiarities of their physico-chemical structure; but in so doing it overlooked the fact that the specific structure of a living organism can itself be shown by experiment to be dependent on the influence of its environment. The mechanistic theory was thus in reality constantly reasoning in a vicious circle. It separated anatomy or morphology, as dealing with structure, from physiology as dealing with activity, whereas any such fundamental separation is impossible, since living structure is merely the expression of living activity. Structure and activity are inseparable aspects of a co-ordinated whole which is specific or normal for each species of organism, and indeed for each individual organism.

The mechanistic theory, as represented in the *De Homine* of Descartes, or in writings of the mechanistic biologists of the latter half of the last century or of to-day, does not hang together, any more than the vitalistic theory. We have all been brought up on the mechanistic theory, as represented in the writings of such men as Huxley, and embodied in present-day popular literature. It is thus an intellectual wrench to abandon this theory; but, though it may survive as a widespread form of belief for many years, abandon it we must. When we abandon it, without returning to vitalism, we can form a satisfactory conception of biology, as being a branch of science which is progressively revealing to us, not the mechanism of life, but a more and more detailed knowledge of the structures and activities which express life as such—as a whole which in the case of each organism exists as specifically or normally co-ordinated structure and activity.

Biology and the New Physics.

This conception of life is, of course, in itself a direct challenge to the ordinary Newtonian interpretation of the visible and tangible world, as represented in traditional physics and chemistry, and amounting to the treatment of Nature as essentially chaotic in the sense already defined. A few years ago that challenge would, apart from the challenge of the eighteenth-century philosophers and their successors, and of ancient Greek writers, have stood alone. But physicists and mathematicians have now themselves joined in the challenge, and have come to regard the traditional Newtonian physical conceptions as no better than preliminary or provisional modes of interpretation. So far as I am able to judge, the new physical conceptions of the last few years are so closely allied in certain fundamental respects to the biological conception which I have tried to explain that the latter conception is no longer a direct challenge to them, but furnishes hints for their further development, while conversely the new physical conceptions furnish hints to biologists. In other words, physics and biology are coming together, not on the lines of reducing biology to the status of a branch of the old physics and chemistry, but on the lines of so fundamentally modifying the conceptions of physics and chemistry that a meeting-point between biology and the physical sciences can be anticipated. Even if that meeting-point were reached, however, individual life would still appear struggle against chaos, since the warring units of a universe of life would still be chaotic.

Importance of Human Biology.

It is in the lives of the most highly organized orga when they are physiologically intact, that we can most sharply and easily the wholeness of life. It is fore with their study that biology naturally begins. far as human life is accessible to observation, biology tells us more, and tells it more clearly, tha the biology of lower organisms. The human subj observation can himself tell us what animals cann It is also easy, with a human subject, to control the conditions of an experiment. To observations m the course of medical and surgical work, and under v conditions of human activity and environment, we very great part of biological advance. With every moreover, the human subject becomes more and more sible to experimental investigation. It is not merely, fore, because human physiology and anatomy are pensable in practical medicine that they are of importance, but because they afford so much a scientific insight into the phenomena of life. Wi mechanistic physiology, which aimed at referrin characteristic features of physiological activity to peculiarities in the structures of different organ tissues, both human experimental physiology an physiology of intact organisms of every kind tende thrust into the background.

I can speak from personal experience on this My own experimental work as a physiologist ha mainly in human physiology; but I had for long to ac myself to its being regarded as of little real sc importance, since it was done on an intact and ver plex organism. As a matter of fact the work engaged on was of great scientific significance, and the case of much other physiological work, it wa on normal and intact human subjects that it co carried out.

The scientific, as well as practical, significance of experimental physiology is now far more widely rec than it was a few years ago; but I think that a goo remains to be done in the way of getting rid practical and theoretical teaching based on the mech idea of life. It is not merely because of its irrelev practical medicine, but because of its scientific that this teaching seems to me very unsatisfactory. the study of an isolated organ or tissue we can co learn much; but we learn only a little about h organ or tissue behaves under normally occurring tions. This is because we have violently altered normal limits the conditions of environment which maintains in the intact organism, and have thus m responses of the organ or tissue abnormal, so that not discover how it behaves in the intact organism. an anaesthetized, though otherwise intact, animal in a normal state. We are thus apt to miss kno which we should gain at once from experiments intact or nearly intact organism. The search for ima "mechanisms" diverts us from the search for wh be found.

From the behaviour of an isolated perfused kid lung we gain little or no knowledge of the a delicacy with which the kidneys and lungs in an man or animal regulate the composition of the i body fluids. Attention is, in fact, directed away fr regulation, whereas when the living body is intact ments which are easily carried out on man reve regulation in the most striking manner. Reg or co-ordination means nothing fundamental f mechanistic physiology, and thus receives very little tion, or is twisted round so as to be made to appea it were nothing but a sort of mechanical balance, dent on innate peculiarities of structure or compo It is common, for instance, to speak of the regula reaction in the living body as if this were an equilibr acid and base, maintained approximately steady presence in the body of buffering substances, instea

physiological activity. Language of this sort is imagined to be scientific: it seems to me only evidence of lack of scientific insight. A similar remark applies to such expressions as the "mechanism" of heredity, or of secretion or respiration. In actual fact the structure is bound up with the regulation, so that co-ordinated or regulated activity is a primary feature in life. In other words, the functional significance of biological structure and activity is of its very essence. The application of the word "mechanism" to life amounts to the assertion that this is not true.

Not only practical Medicine, but also Biology itself as a science, is dealing with the essentially and specifically co-ordinated structure and activity which we call life. In laying no primary stress on the co-ordination or regulation the mechanistic physiology has not only tended to divorce itself from practical Medicine in the manner we are all painfully aware of, but is radically unsound in a scientific sense. It is life as an essentially co-ordinated whole that physiology, no less than practical Medicine, has to keep in view. Practical teaching which consists mainly in experiments on isolated fragments of frogs or other animals, and in isolated chemical experiments on substances occurring in the body, is no satisfactory instruction in Physiology as a science.

The Hippocratic Foundation of Medicine.

I have already remarked that life appears to us as a constant struggle for organic order in an otherwise chaotic world, and that the function of Medicine is to give assistance in that struggle where assistance is called for. In order to give this assistance effectively we must know in detail how the struggle is normally conducted successfully during health. We must thus know normal anatomy and physiology, and this implies also a knowledge of physics and chemistry, without which we should be ignorant of what life is struggling against, or of the very existence of a struggle. Normal anatomy and physiology would include all the knowledge that can be obtained of the local conditions on which normal local structure depends, and of how attacks by foreign organisms are normally repelled. From such knowledge we can already see to some extent where failure in the struggle for normal life is liable to occur, and how such failure can be guarded against.

For the purposes of practical Medicine we must, however, push our investigations far outside the limits of normal physiology and anatomy, and study the consequences of quite unusual or not yet understood disturbances in environment, including, for instance, more or less successful attacks by foreign organisms. For Medicine the symptoms, such as pain, depression, wasting, failure of function, or abnormal behaviour, are all signs of a disturbance in normal environment. In such cases the struggle for life has been at least partially or temporarily unsuccessful; but the Hippocratic conception implies that there always is a struggle. Usually the struggle is more or less successful in the end, so that health is re-established. Sometimes, however, the struggle is more or less unsuccessful, and results in permanently impaired health or death unless conscious intervention in the struggle is effective.

It is on this struggle against abnormal disturbances, and the means of helping in it, that medical science must centre its attention, as Hippocrates first pointed out. For mechanistic biology there is no real struggle, and if the mechanistic biology represented truth we might despair of anything further than preventive Medicine of a very restricted kind. But on this point I am heart and soul with Hippocrates, and with the traditional faith which he inspired in the ranks of our profession. I have already explained why, as it seems to me, the mechanistic conception of life is inadequate in physiology and morphology. For the same fundamental reasons it is inadequate in Medicine, and in pathology, pharmacology, and therapeutics.

To assist Nature in her struggle we must understand the struggle as fully as we can. To realize the disturbances which are confronting her we need all the physics and chemistry which are essential in normal biology, as well as what can be applied to the abnormal conditions causing disease or injury. We also need to know the biology of invading organisms if the disturbance is due to them. On the other hand, we must understand how, in detail, the struggle against the disturbance is being carried on, and we must not mistake, as we are very apt to do, the evidences of this struggle for the primary disturbance itself. It is only by patient observation, thought, and experiment, recorded, or communicated by example and orally, in the spirit of the Hippocratic oath, and continued from generation to generation, that we make progress in Medicine; but assuredly the evidences of that progress were never so striking as in our own times, or the prospects of further advance more encouraging.

Medicine has progressed along the Hippocratic pathway regardless of the mechanistic theory of life; but I think that with a more adequate biology, including proper regard for human physiology, and the definite establishment of anatomy or morphology as an experimental science just as much as physiology is, the progress will be still more rapid. I have tried in this address to give reasons for the conclusion that the mechanistic theory of life is an insufficient foundation for Medicine, and that the Hippocratic foundation is the only secure one. I well know how many, particularly outside our own profession, will be inclined to disagree with me, and I wish this address had been a less controversial one. But I am convinced that specifically biological knowledge is the scientific basis of Medicine, and that it is of very great importance to Medicine, as well as to biology itself, to be clear as to the fundamental conceptions on which biology is based. In the process of clearing our minds controversy is unavoidable, and this must be my excuse for being controversial.

EXCESSIVE AND IRREGULAR UTERINE BLEEDING IN MIDDLE-AGED WOMEN.*

BY

S. GORDON LUKER, M.D.CAMB., F.R.C.S.ED.,

OBSTETRICAL SURGEON, LONDON HOSPITAL.

THE causes of uterine haemorrhage fall into two main groups—those which are and those which are not connected with recent pregnancy. This paper is concerned with middle-aged women between the ages of 40 and 50, who have passed the child-bearing age and are therefore free from the causes of bleeding connected with pregnancy. They are subject some time during this period to the changes of the menopause, which usually consist in a diminution of the amount of the menstrual bleeding and its duration. Sometimes a period or two are missed, and a small period occurs every two or three months or at increasing intervals; occasionally, after an interval of two or three months, the next period is rather severe, amounting to a flooding; but anything in the nature of irregular or excessive bleeding is abnormal, and must be regarded with suspicion.

For clinical purposes cases of uterine haemorrhage fall into the following three groups:

1. The menstrual periods are regular, but prolonged or excessive in amount—commonly called menorrhagia. This is found most commonly in the case of fibroids, hypertrophy of the endometrium, chronic metritis, and chronic subinvolution.

2. The bleeding is excessive and irregular, or there is bleeding at times other than the menstrual periods—commonly called metrorrhagia. This suggests malignant disease—for instance, carcinoma of the cervix, or, less commonly, the body of the uterus; sometimes it is due to one of the conditions mentioned in the previous heading which has gone on for some time.

3. Bleeding occurs at some interval after the menopause and may be only slight in amount, even just a show. This always suggests malignant disease, but is occasionally due to some non-malignant cause.

1. REGULAR BUT EXCESSIVE BLEEDING.

If the bleeding is excessive and regular (menorrhagia) the most likely cause is some innocent condition—namely, (*a*) uterine fibroids, or (*b*) a group including hypertrophy

* A paper read to the Bournemouth Medical Society.

of the endometrium, chronic metritis and endometritis, and chronic subinvolution, which can conveniently be discussed together.

(a) *Uterine Fibroids.*

It has been stated that nearly 20 per cent. of all women get a fibroid tumour of the uterus. In many instances the tumours are small and cause no symptoms; nevertheless operations for fibroids form a large proportion of all gynaecological operations. The diagnosis generally rests on a history of menorrhagia with an irregular enlargement of the uterus. If, however, there be only one small fibroid polyp in the uterus the increase in the size of the organ may not be sufficient to be detected by bimanual examination, and the diagnosis must be tentative until confirmed after dilatation of the cervix and exploration of the uterine cavity with the finger. For fibroids operative treatment is nearly always the best so soon as advice is sought for bleeding, or a lump, or for pain. Pain is a rare symptom, but may be caused by pressure effects or by red degeneration. After the age of 40 removal of the fibroid by vaginal or abdominal myomectomy, which is the operation of choice in younger women, is less often indicated than hysterectomy, which is a straightforward and safe operation and removes from the woman, who has finished with child-bearing, an organ which may otherwise give rise at any time to discharge or bleeding, or may become affected by malignant disease. Fibroids do not cease to cause symptoms after the menopause, but often delay or prevent it.

The treatment of fibroids by radium or x rays is not to be advised unless there is some reason—such as real obesity with fatty heart, or severe diseases of some other system—why the patient should not have an anaesthetic and an abdominal operation. Though neither radium nor x rays can "disperse" the tumour, they may cause degeneration and subsequent sepsis; and there is always the chance that the tumour may be associated with carcinoma of the body of the uterus, or, more rarely, may be a sarcoma. Radium acts by destroying the endometrium, but has no effect on the fibroid, which may degenerate and become infected after the radium treatment; and it is not a certain cure for the bleeding. The use of x rays, which act entirely or mainly on the ovaries, producing an artificial menopause, is contraindicated. It is a modern method equivalent to the old operation of oöphorectomy for fibroids, which has been abandoned for years. The tumour of the uterus remains and may undergo acute septic degeneration requiring operation. The treatment by x rays is prolonged and tedious, and its only justification is where fear of an operation cannot be overcome. There are, however, some ill effects, such as burns and general anaemia, which may follow the application of x rays.

(b) *Hypertrophy of the Endometrium, etc.*

In this class are those who have excessive bleeding of the menorrhagic type, but have not got fibroids or malignant disease; the uterus is a little enlarged and its walls thickened, though this change is not always sufficiently marked to be detected by bimanual examination. The uterine walls are thicker and firmer than those of a normal uterus, and contain a greater proportion of fibrous tissue; there are changes in the vessels such as occur during involution after parturition—namely, the formation of new vessels inside the old—but these are not complete, as shown by the presence of a new layer of elastic tissue in the vessel; there is a condition of subinvolution, and round-celled infiltration is present, indicating that the change is of an inflammatory nature. According to the predominant change the condition may be called "fibrosis uteri," chronic metritis, or chronic subinvolution. The old clinical term "heavy fibroid uterus" is reasonably correct. Changes in the endometrium are present also—sometimes a hypertrophy with formation of polypi, sometimes a thickening with an increased amount of glandular or interstitial tissue (endometritis).

The treatment of this condition is far from easy. Drugs such as iron and ergot have been used very extensively, but in many cases their action is far from satisfactory. The most useful drugs are calcium and pi is best given as fresh calcium lactate, n bining lactic acid with precipitated ca 60 grains should be taken every day for a should be given by intramuscular injec 0.5 c.cm. If this treatment is not su investigation should be carried out under A laminaria tent is inserted into the c night, and next day the cervix is dilat 19 or 20, so that the finger may be passed which is then investigated bimanually s mucous fibroid or polyp may be felt and re will then show whether the endometriu a microscopic section should always be p to ascertain the nature of the endometriu the presence of malignant disease. The cluded by swabbing out with tincture of i a hot intrauterine douche. After such number of patients—those who have hy endometrium—will be improved and som others, however, will be no better than b be treated with radium or by hysterectom

Radium therapy is most useful in these a complete cessation of bleeding in thr cases, and relapses of severe bleeding ar action is on the endometrium; it causes the hypertrophied and congested uterine m which is afterwards replaced by healthy ce perivascular fibrosis and proliferation o cells of the enlarged uterine blood vessels progresses to a condition of endarteritis

The dosage required is 100 mg. of radiu duced into the uterine cavity for twen 50 mg. for thirty-six hours. The radium tained in a small tube of platinum 1/2 mm platinum acting as a screen for the h rays. This is placed in an outer tube o thickness, with a long silver wire attac tube acts as a useful container and an ex secondary rays. As the dosage of radi alluded to in terms of element, it is use radium bromide contains, roughly, 50 pe element.

The method of application consists in tube of radium into the uterine cavity thetic. The patient is prepared as for a tion. The cervix is dilated and the u plored with the finger or a curette, accor of dilatation. By following this method confirm the diagnosis that there is no the uterus and to exclude the presence of endometrium of the body of the uter safest, even if nothing abnormal is found scopical section made of the endometri curettage, as in a small percentage o show unsuspected malignant changes. A uterine cavity is douched and swabbed ou spirit, and the tube containing the ra attached, is introduced into the uteri vagina is plugged in order to prevent the tube by the uterus. After twenty-four is pulled out of the uterus by traction o this is easily done, and there is no risk closing down and preventing removal of usual result is complete cessation of bleed instances one or two slight periods occur ing ceases; occasionally there is one exces amenorrhoea is established. In the sm cases which are not completely cured the for from six months to a year, and then to return. Such cases are sometimes c application of radium, but hysterectomy cated. Second applications of radium a as the first.

Contraindications to the use of rad cervicitis and laceration of the cervix erosion and much discharge, and any salpingitis. In the latter, acute salpingi by the radium application; in the forme be suspect for carcinoma.

Treatment by extracts of endocrine glands is disappointing. When signs of thyroid deficiency are obvious the administration of thyroid gland will cause a general improvement in health, and with this an improvement in symptoms of menorrhagia; but it is quite unusual to find these signs in a woman who is suffering from excessive bleeding about the time of the menopause. Pituitary extract is certainly useful for its immediate effect on the uterus, but its effect is not prolonged. In slight cases a series of injections of pituitary extract are useful in tiding a patient over a prolonged or excessive period. These are the only two extracts which can be relied upon in the treatment of bleeding at the menopause. The various forms of ovarian extract, corpus luteum extract, and combinations of these with other extracts, have no action which can be relied upon. It is probable that the preparation of the extracts destroys the active principle. Occasionally good results will be obtained, but these are so rare and uncertain that use of these extracts cannot be considered therapeutically scientific. The excessive bleeding results from retrogressive changes in the uterus which cannot be controlled or affected by ovarian medication.

2. IRREGULAR AND EXCESSIVE BLEEDING.

Carcinoma of the cervix uteri is very common; some irregularity in bleeding, or blood-stained discharge, or bleeding, it may be slight, or blood-stained discharge, or is usually present, but the onset may be very insidious, and the first unmistakable sign may appear only when the disease is well advanced; this is especially true when the growth has originated in the cervical canal. It has thus become the accepted rule that any, and every, woman who complains of any excessive or irregular bleeding or blood-stained discharge, particularly about the time of the menopause, must be examined with the greatest care; if there is no palpable or visible sign of carcinoma of the cervix there still remains the possibility of carcinoma of the cervical canal or body of the uterus. This may necessitate careful examination under an anaesthetic; the cervical canal and uterine cavity must be thoroughly dilated and examined, and the scraping or curettage sent for microscopic section. The importance of diagnosis and treatment at the very earliest moment may be emphasized if it is realized that in the out-patient departments of hospitals two cases of carcinoma too advanced for operation are seen for every one that is operable.

The best treatment of carcinoma of the cervix is by an operation removing the whole uterus and appendages with a cuff of vagina, as freely as possible, with the cellular tissue round the cervix and the iliac glands. The results of this operation, when performed by those who have made themselves familiar with it, are surprisingly good; roughly 40 per cent. of the cases are cured and free from recurrence after five years, according to the latest expert figures available. The primary mortality is quite small; patients who suffer a recurrence have a period of from one to five years of freedom from pain, even from discomfort, and the terminal stages are characterized more by a general debility than by the awful bleeding and foul discharge which is present when no operation has been done. This radical operation is undoubtedly the best treatment so long as the condition is operable. The treatment by radium cannot compare with this, and as a curative agent it must take second place. Its effect is to cause improvement in the local condition for from six to twelve months. As an adjuvant, or in the treatment of inoperable cases or for early recurrences after operation, its palliative effects may be beneficial.

3. BLEEDING AND BLOOD-STAINED DISCHARGE OCCURRING AFTER THE MENOPAUSE.

This always suggests malignant disease; but whereas before the menopause and the age of 45 cancer of the cervix is twenty times more probable than cancer of the body of the uterus in women who have borne children, as the age of 50 is approached the probability of carcinoma of the body of the uterus becomes equal to that of carcinoma of the cervix.

Cancer of the body of the uterus starts in the epithelium or glands of the endometrium and is less rapid in its growth, remaining local for a much longer time; except in its advanced stages it can only be diagnosed by exploratory curettage or digital examination of the uterine cavity. The large majority of cases are operable when first seen, and the operation of pan-hysterectomy is followed by very good results. Patients in this class must generally be given an anaesthetic to confirm the suspicion of cance of the body; if cancer of the body is not present, senil endometritis will be found, and this will be cured l curettage.

When cancer of the body of the uterus has becor inoperable palliative treatment alone is left; the grow extends to the surrounding structures and the intestir and neither radium nor x rays can be used with safety.

THE EPIGLOTTIS IN RESPIRATORY OBSTRUCTION UNDER ANAESTHESIA.

BY

H. MORTIMER WHARRY, F.R.C.S.,

ASSISTANT SURGEON TO THE THROAT AND EAR DEPARTMENT OF THE BOLINGBROKE HOSPITAL.

RESPIRATORY obstruction under anaesthesia is a matter of considerable importance to every anaesthetist, but of vital interest to the throat surgeon. I do not propose to deal with the minor crises which arise during the course of an anaesthetic, and are overcome by such simple but all-important manipulations as forcing apart the clenched teeth, gagging open the mouth, holding the jaw forward, pulling out the tongue, swabbing mucus or blood out of the throat, and performing artificial respiration. My object is to push a step further in the knowledge of causes of dyspnoea in the normal air passages. The emergencies I have in mind are rare, but when they do occur, usually result either in the performance of a tracheotomy or in the death of the patient, or sometimes both.

Having had the opportunity of dealing satisfactorily with a number of these cases, and of making certain definite observations in the course of treating them, I fee justified in making some suggestions as to a routin method of procedure to be followed during the very sho interval of time which elapses between unrelieved respir tory obstruction, subsequent cardiac failure, and t patient's death.

There can never be any doubt as to the identity of t clinical picture, which must be diagnosed from cardiac respiratory failure due to shock, chloroform poisoning depression or poisoning of the respiratory or car centres in the central nervous system.

The patient's colour affords the first indication all is not well. The cyanosis is often concurrent with difficult or poor respiratory movements. This change of hue gradually becomes intensified and is soon dark blue with a blackish tinge. Respiration ceases altogether, and the pulse becomes rapid and feeble. The mouth is gagged open, the tongue pulled out, and artificial respiration is performed, but without effect. The pharynx is swabbed clear of mucus and an oxygen tube introduced in vain.

There is clearly some laryngeal obstruction, and if this is relieved at once the situation is saved, but if not the heart finally ceases to beat, the colour turns from blue-black to white, the skin surface turns cold, and the flesh when cut no longer bleeds. At this point the patient is technically dead, but may be resuscitated within two minutes.

I propose to deal with this type of crisis in two stages: (1) When respiration ceases, and efforts to restore it have failed owing to an obstructed airway, but the circulation is still maintained. (2) When respiration has ceased for so long that the circulation fails also. The treatment of stage 1 is so closely concerned with the epiglottis that I cannot do better than discuss this structure from the point of view of anaesthesia.

ere there is no laryngeal disease the epiglottis is the
o the lower air passages. Although the laryngeal
cter, consisting of the arytenoid, thyro-arytenoid, and
-aryepiglottidean muscles, may be thrown into spasm,
only occurs when anaesthesia is so light that the
geal reflex is present. The spasm passes off of its
accord in a short time and does not occur under
anaesthesia.

Anatomical Varieties of Epiglottis.

The epiglottis may be of the "overhanging" variety.
is to say, that when observed with a laryngeal mirror
larynx cannot be seen, but only the anterior surface
he free part of the epiglottis. The upper end is
ly approximated to the posterior pharyngeal wall,
when the tongue is pulled forward, as is usual during
ect laryngoscopy. It is easy to understand that if
tongue falls back under anaesthesia, such an epiglottis
lie right over the laryngeal and oesophageal openings.
) The epiglottis may be of the "dead leaf" type.
is to say, it is curled laterally upon itself, the two
being bent backwards and approximating to the
re. This type also hides the glottis to a certain
nt, and may overlap it under anaesthesia.
) The epiglottis may be quite normal in appearance
yet have the following slight variations: It may be
paratively long, short, thick, thin, broad, narrow,
l, soft, rigid, or pliable. And yet if it was to be
mined during an autopsy it would not attract any
ntion. I have known an epiglottis (which was a little
, thin, soft, and pliable) nearly cause a patient's
th by becoming impacted over the larynx. But when
mined *in vivo* afterwards by the indirect method it
ed the same as any other epiglottis, with the exception
the slight divergencies mentioned.
When I refer to the length of the epiglottis I mean its
jection above the base of the tongue. This will be
nd to vary in different individuals.

The Physiological Functions of the Epiglottis.

The epiglottis serves two important purposes, apart from
influence in modulating the voice:
a) It acts as a protection to the larynx from the normal
retions in the mouth. If it were not for its position and
mation saliva which now collects either in the valleculae
pyriform fossae would drip into the trachea and cause
stant coughing.
b) Opinions differ as to its exact function in swallow-
. It was held at one time that during deglutition the
glottis was folded over the laryngeal aperture like a
ering, but more recently other observers, notably Pro-
sor Anderson Stuart, have shown that the larynx is
it off by the sphincteric action of the thyro-arytenoid
d arytenoid muscles, and that the epiglottis is only
ed backwards by the thyro-aryepiglottidean muscles so
to form a slight cowl-like protection.
But bearing in mind the various anatomical and physio-
ical details of this region, the projection of the epi-
ttis above the tongue, and the powerful muscular action
swallowing, it seems impossible to avoid the conclusion
at so flexible a structure, even if not pulled over the
yngeal aperture by muscular action, could hardly avoid
ing swept down on to it by the passage of a bolus which
s accurately against the whole circumference of the
arynx. In fact, although it is not possible to bring
rward any definite proof, it seems extremely likely that
swallow our epiglottis as far as it will go at every act
deglutition, and it would probably cause us to choke if
were not for the normal interval of reflex respiratory
ssation after swallowing which allows it to recover its
rmal position.
Seeing that the coughing reflex is abolished before that
swallowing, it follows that there is an interval of
me when the epiglottis may be drawn over the larynx
a swallowing movement while the protective cough
flex is absent.

I have not entered into these anatomical and physiological details in order to prove or support any particular theory, but to try to find some explanation for a clinical fact which I have repeatedly experienced—that is, complete obstruction to respiration under anaesthesia caused by the epiglottis alone. It is most often to be found when the patient is in the tonsil position with a sandbag under the shoulders, but may occur in other circumstances also. In these cases I have made the following observations by digital examination.

1. A long epiglottis is sometimes found tightly impacted over the laryngeal aperture, with its extreme end curved up and closely applied to the posterior pharyngeal wall (see diagram). This type is difficult to disimpact owing to the awkwardness of passing a finger between the opposite surfaces of epiglottis and pharynx. But as soon as the epiglottis is pulled forward and pressed against the base of the tongue with the finger a free airway is instantaneously restored. An epiglottis so impacted acts as a valve allowing air to escape from the chest, but none to re-enter, and affords an obvious explanation why artificial respiration in such a case is foredoomed to failure until the airway is cleared.

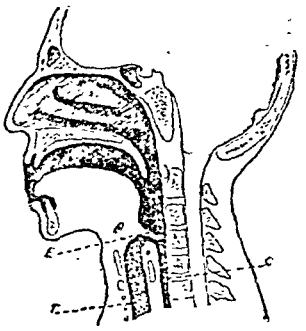

Diagram showing how a long and flexible epiglottis sometimes lies over the laryngeal aperture under anaesthesia. T, Trachea. E, Epiglottis. O, Oesophagus. The author has seen three cases of complete, and many cases of partial, obstruction to respiration from this cause. Its pernicious valve-like action is also seen. Air is able to leave the chest, but inspiration is prevented by the epiglottis being drawn on to the larynx by suction. Artificial respiration is of no avail until it has been raised by the finger and pressed into its normal position against the base of the tongue, where it is held until danger is past.

2. An epiglottis which, although not tightly impacted, is nevertheless lying in contact with the posterior pharyngeal wall. It is possible that this type is an early stage of the first, and only requires a vigorous inspiratory effort to draw it on to the larynx by suction. It is common to find this clinical feature in many cases of respiratory difficulty, from the mildest to the more severe. To raise the epiglottis, and press it against the base of the tongue with the finger, again affords instantaneous relief, and artificial respiration can then be applied with confidence and success. If for any reason this fails to secure a free airway, a laryngotomy can, of course, be performed. But I have never failed to secure a free airway by these methods, and such a case has never got worse progressively until the heart ceased to function, except in cases where there was obstruction due to actual laryngeal disease.

If, however, the condition has progressed to stage 2 before it is relieved further measures must be taken.

Treatment of Failure of Respiration and Circulation due to Respiratory Obstruction.

A. "*No Man's Land.*"

There is a certain region which lies between the domains of "life" and "death." All the signs of death are present: there is no breath, no visible, audible, or palpable sign of a heart beat or pulse, the surface of the skin is cold, the colour is a bluish-white, and when the flesh is cut the wound does not bleed but yields only a few drops of dark fluid. No one knows definitely how long a man may stay in this region and still climb back to life. The most optimistic would not put it at more than three minutes or the most pessimistic at less than two. So that when a patient under anaesthesia loses both respiration and circulation, the surgeon, anaesthetist, and theatre staff have only a short time at disposal, and they must use this time to the greatest possible advantage in restoring him to life.

B. *Minimum Requirements for Resuscitation.*

These are mainly physiological, and consist of (*a*) a free airway; (*b*) the presence of sufficient oxygen in the lungs to oxygenate the blood in the alveolar capillaries to the fullest extent possible; (*c*) the passage of that blood into the left auricle; and (*d*) sufficient movement of the heart to force some oxygenated blood through the aortic valve so as to enable it to circulate through the coronary arteries, and supply the heart muscle with enough oxygen to allow it to contract automatically. I make no mention of the respiratory and circulatory centres in the central nervous system, because our knowledge of them is theoretical rather than practical, we cannot exert clinical influence upon them in the time at our disposal, and we know that local treatment of the lungs and heart will produce the desired effect if accomplished in time.

To elaborate these requirements in terms of practical performance is a simple matter.

1. As soon as the emergency arises one individual must start doing artificial respiration and maintain it continuously and without ceasing for any reason, being relieved by another at any necessary intervals. Artificial respiration should be regular and unhurried, but very forcible; and should compress both lungs and heart.

2. Simultaneously another gags open the mouth, and introduces the finger as far as the larynx, raises the epiglottis and presses it forwards against the back of the tongue. If the airway is now quite free the fact will be obvious because the breath will be heard coming and going easily under the force of artificial respiration. If not, a laryngotomy or tracheotomy should be performed immediately and without hesitation, a laryngotomy being quicker and easier than a tracheotomy.

3. While this is going on a third person has brought forward the oxygen cylinder and turned on the oxygen with propulsive (but not explosive) force, and holds the tube ready to the operator's hand when he calls for it, which he does the moment the airway is free.

As soon as the operator has established the airway and holds the oxygen tube in his hand, he first tests the power of the stream of oxygen and then introduces it into the laryngeal aperture or directly into the trachea in the case of a laryngotomy or tracheotomy. The lungs are thus, in the shortest time possible, flooded and washed out with oxygen aided by powerful artificial respiration.

If these three people know what to do beforehand and act simultaneously the utmost relief is supplied within a few seconds, which is an all-important factor in treatment. The necessary movements of the heart to induce the initial automatic contractions can be brought about in the majority of patients by the vigorous passive movements of the chest wall which I have already described. Special attention must be paid to compressing the cardiac area, and this can always be done, with the possible exception of certain individuals with unusually rigid chest walls. As soon as this is accomplished and the alveolar air has been flooded with oxygen, the heart, which has been stimulated and supplied with oxygenated blood, starts to beat and the crisis is relieved.

C. *The Opening of the Abdomen below the left Costal Margin and Massage of the Heart through the Diaphragm.*

I mention this procedure because it has received a certain notoriety, but I doubt its applicability to the obstructive type of case, whatever its merits may be in primary cardiac failure when the airway is free. It is obviously useless to compel the heart to circulate fresh quantities of the venous blood which in the first place brought it to a standstill. Such an action is bound to have a deleterious effect upon the heart muscle, and possibly accounts for the occasional failures of this operation. But if the lungs have previously been flooded with oxygen in the way I have described, and fresh supplies of arterial blood laden with oxygen are occupying the pulmonary veins and left auricle and merely awaiting a beat or two of the heart to put them into circulation, then such an operation may possibly be justified. The only thing against it is that it is then usually unnecessary. The heart in most cases is readily susceptible of stimulation through the chest walls except in those whose ribs are unusually rigid, and I think this abdominal incision of problematical efficacy should be reserved for such cases. When it is employed, artificial respiration should be interrupted for as short a time as possible while the operation is actually taking place.

The Use of Drugs.

While the usual cardiac and respiratory stimulants may be of some avail when once the circulation is restored, it must be obvious that no medicines can supply oxygenated blood to the left side of the heart and so to the coronary arteries, which is the fundamental requirement at these critical moments. Nor can they reach the structures they are intended to influence until the restored circulation will carry them to their objective.

Equipment.

When there is so short a time in which to act, it is obvious that unless the necessary instruments are ready to hand the surgeon and anaesthetist will be seriously handicapped in their efforts at resuscitation. I would therefore suggest that the following instruments should be added to the usual list and kept under cover on the anaesthetist's table instead of on a shelf or in a cupboard in the operating theatre or instrument room.

1. A spatula with a blade long enough to reach the epiglottis. People with short fingers find great difficulty in holding up the epiglottis for any length of time because of the weight and power of the tongue. If such a spatula cannot be obtained, a closed sponge-holder will sometimes suffice, using the teeth of the upper jaw as a fulcrum. But the best instrument is the forefinger.
2. A scalpel.
3. A laryngotomy tube with introducer.
4. A "bi-valve" tracheotomy tube. This needs no introducer, and is the easiest type to insert.
5. A tracheal catheter.

In addition to these a properly mounted oxygen cylinder is of great use. It should either be full or have a reserve cylinder alongside. The cylinder in use should have a coarse and fine adjustment. The oxygen outlet should be ready fitted with a long rubber tube to give to the operator without delay. If it is necessary to deliver oxygen directly into the trachea, the tube can be fitted over the tracheal catheter.

CONCLUSION.

Never having heard of the part played by the epiglottis in respiratory obstruction until I discovered it for myself in making a digital examination of the larynx in a patient who was *in extremis*, I have since found this knowledge of great value on several occasions. It enables a tracheotomy or laryngotomy to be avoided, it makes it possible to complete an operation which might otherwise have to be abandoned, and it may save life where instruments for tracheotomy or laryngotomy are not available.

My suggestions as to resuscitation are the result of observations on two successful cases where both respiration and circulation had entirely ceased, and where cardiac massage through an abdominal wound was found to be unnecessary. While there is nothing new in clearing an airway, performing a laryngotomy, flooding the lungs with oxygen, performing artificial respiration, or stimulating the heart through the chest wall, I was nevertheless impressed with the advantages afforded by simultaneous team work in providing thorough treatment at the earliest possible moment. I was further influenced by the reflection made at the time, that to have interrupted this work in order to perform an abdominal operation, however short, would probably have resulted in the patient's death, since, as it was, there appeared to be hardly a moment to spare from the task of getting oxygen into the alveolar air.

ALBUMINURIC RETINITIS IN ONE EYE, EMBOLISM OF THE CENTRAL RETINAL ARTERY IN THE OTHER.

BY

W. M. BEAUMONT,

BATH.

CASES of monocular albuminuric retinitis, with no sign of involvement of the other eye up to the time of death, have not been very frequently reported, and we are indebted almost entirely to American, French, and German sources for literature on the subject. But nowhere can I find any reference to the effect of a pre-existing disease of the retina in the case of a patient suffering from nephritis. For this reason the following fragmentary notes, however incomplete, seem to be of sufficient interest to record.

T. H., aged 37, consulted me on November 19th, 1918, because, twelve days previously, he had suddenly become blind in the right eye. He had had a transient attack of dimness in that eye a month earlier. He could just count fingers, but with the other eye he read 6/6. The right pupil hardly reacted to light, but responded consensually. Ophthalmoscopically the picture was that significant of embolism of the central artery of the retina. The external half of the retina was very anaemic, and the vessels were reduced in calibre and appeared as mere threads through the gloomy media. In the macular region a "cherry-red" spot was dimly visible.

On November 27th there was less haze, and between the cherry-red spot and the disc there were four small haemorrhages. He had no perception of light in the eye. On December 18th the cherry-red spot was smaller, and between it and the very white disc were a number of glistening white spots.

On January 14th, 1919, there was advanced atrophy of the disc and the glistening spots had disappeared. On March 25th there was pigmentation around the disc, and the contrast with the white nerve head was very noticeable. The report of his doctor that there was no evidence of cardiac or renal disease was confirmed. His Wassermann reaction was negative.

I did not see him again for six years, when he came to me on March 10th, 1925, with a diagnosis of Bright's disease associated with right total and left partial loss of sight. In the latter eye the dimness had been coming on for several months. On examining the right eye the disc was found to be absolutely white and there were only to be seen a few threads which had once been arteries. The condition of the eye was consistent with the history. There was no retinitis. The left eye showed an intense neuro-retinitis with white patches of exudation covering the retina, and there were two haemorrhages below the disc. The vessels were small when they could be seen, but they were mostly hidden by the exudation. There was no stellate figure. He was very restless and had other signs of an approaching collapse. The urine showed albumin and casts, and the specific gravity varied daily between 1016 and 1020. Towards the end of his life it dropped to 1010, and there was only a trace of albumin and no casts. He had very little oedema of the body or limbs, and it was not more marked on one side than on the other. Death occurred on May 1st without any sign of retinitis in the right eye, the last examination having been made the day previous to his death.

I am much indebted to Colonel J. Cowan for the report of the *post-mortem* examination and for his help with the pathology.

The heart weighed 571 grams (about 20 ounces). On the right side there was marked hypertrophy of the ventricle. There was stenosis of the mitral valve (it admitted the forefinger up to the first *joint only*). The cusps were thickened and rigid; no recent vegetations. No atheroma in the aorta. Coronary arteries patent, but probably somewhat sclerosed. Both kidneys were present and were equally affected. Each weighed 107 grams (about two-thirds of the normal)—chronic granular contracted (small red) kidneys. There was profuse cystic degeneration of the cortex of each kidney. The cause of death was returned as (1) chronic nephritis, (2) uraemia and failure of the right heart.

Post-mortem examinations of patients who have had monocular albuminuric retinitis at the time of death have not often been reported, and it seems probable that such cases are extremely rare. Nevertheless there is divergence of opinion regarding the binary frequency of albuminuric retinitis, as the following selection of authorities will show:

Parsons: "The condition is almost always bilateral."[1]

Knies: "Usually bilateral, though it does not always begin at the same time. Unilateral cases are not very rare."[2]

Sym: "Always bilateral."[3]

Meyer: "The disease generally affects both eyes, but in different degrees."[4]

Noyes: "It is highly exceptional to have but one eye involved; frequently one eye is more involved than the other."[5]

Berry: "Almost invariably both eyes are affected at or about the same time."[6]

de Schweinitz: "Almost invariably both eyes are involved, but in rare instances the affection has been monocular." This author has observed one such case.[7]

de Wecker: "While in simple apoplectiform retini were not infrequent in which the affection was limited to or did not attack the second until late, nephritic retinitis commences simultaneously or within a short interval in bot

Swanzy: "Both eyes are as a rule affected, though equally so. A few cases are recorded in which only one attacked, and in several of them it was found that but or was present."[9]

Yvert: "Has seen it once affecting one eye only out o one cases."[10]

Juler: "Both eyes are always affected."[11]

The first monocular case appears to have been p by Kirsch in 1870,[12] and since then others ha reported. In Yvert's case[13] the *post-mortem* exa showed that the patient had only one kidney and missing one was from the same side as that on w eye was unaffected. The absence of the kidn apparently saved the sight.

Influenced by this case Yvert advanced the the an irritation is capable of reacting by means sympathetic nervous ganglia upon the whole system of the corresponding side, thus causing dis of the circulation, both in the retina and in t on the corresponding side. This view, he cor was supported by the cases published by Pota which a blow on the loins was followed by limited to, or more pronounced on, the injured s a case of Eales's[15] an alcoholic man fell and inj left loin. The next day he was found to have sight in the left eye. Three weeks later a retinal rhage and retinitis were discovered in that e There was a slight quantity of albumin in the u specific gravity of which was 1014. Eventually the cleared up, but some atrophied patches remain man appears to have recovered his health but vision. The case is recorded as one of "supposed u albuminuric retinitis," but the non-fatal end t grave doubt on the albuminuric cause of the for had it been of that nature death would almost have followed.

In a case reported by Brunnet[16] there was ret the right eye only and marked oedema in the and arm.

With the exception of Yvert's, I cannot find oth in which there was reported to be only one kidn until further support is forthcoming I think theory of irritation of the sympathetic cannot be

The following is a list of other reporters of u albuminuric retinitis, but it is probably inc Leber,[17] Magnus (two cases),[18] Plenk,[19] Che Moore,[21] Weeks,[22] Bull,[23] Marple,[24] Pyle,[25] and Cowan.[26] My patient controverts the necessity absent kidney, and also negatives the interve trauma of the sympathetic. The premisses were tional, different incomparably from all the others the retina was immunized by the pre-existing A retina which has been to some extent conver fibrous tissue is not likely to take on the orthodox ance of albuminuric retinitis.

As the central is a terminal artery the part by it will be completely cut off from nourishme will therefore undergo necrosis when embolism artery occurs. The condition will be eventually a to infarction of the brain. Owing to the situatio retina sloughing of the necrosed tissue will not oc assuming that there is no infection, an attempt at tion will follow. Leucocytes from the adjacent will form a zone around and migrate into the dea New vessels will penetrate the necrosed part, t tissue being more or less absorbed and replaced b tissue. It would therefore be possible for such a area to become inflamed when this healing process h place. Nevertheless it is to be expected that a modification would take place in the eye which viously suffered from embolism. The inflammatory if it occurred at all, would probably show a very picture from that seen in an eye which had been pr the seat of an embolism.

That one cannot generalize from a single case which applies equally to Yvert's and to mine; in suggestion is the absence of a kidney, in mine the of a retinal atrophy.

Embolism of the retina is not a very rare misfortune, and, by the unvarying law of chance, a certain percentage of cases end later by Bright's disease. Examination of a number of these might throw light on the etiology of monocular retinitis.

THE ANTIGEN TREATMENT OF PNEUMONIA IN INFANCY AND CHILDHOOD.

BY

R. AIDIN, M.B., B.CH.,

ALDER HEY CHILDREN'S HOSPITAL, LIVERPOOL.

ECTO-ANTIGENS or immunogens have recently been introduced into biological therapy; the theoretical basis and experimental work on which their manufacture is based have been described by Sir Thomas Horder,[1] and by Ferry and Fisher.[2,3] This type of vaccine is probably less toxic than the older types, so permitting much larger quantities of the specific antigen to be administered without deleterious effects. In the autumn of 1926 I began using immunogen as a routine treatment in all cases of pneumonia and bronchopneumonia, and have compared the results obtained with those of the previous nine months.

All the patients were under 14 years of age, many of the infants suffered to some degree from rickets, a few from severe malnutrition, and in a few the pneumonia was terminal or complicated by severe enteritis. Cases of lobar pneumonia and bronchopneumonia are included, the majority being of the latter type. I have attempted to keep the standard of diagnosis uniform; all patients who showed evidence of pulmonary consolidation and symptoms of toxaemia were diagnosed as cases of lobar pneumonia or broncho-pneumonia, even though the disease was of brief duration. Some of these cases would doubtless have been regarded by others as capillary bronchitis or pulmonary congestion.

It is difficult to estimate the value of any specific therapy in the pneumonias of childhood. In the present series of cases some of the patients who had been ill only a few days, and who on admission showed signs and symptoms of bronchopneumonia, recovered in a few days after one injection of immunogen; but others with similar histories, signs, and symptoms recovered as rapidly without it. The combined pneumococcus immunogen of Parke, Davis and Co. was used; it is an extract of types 1, 2, and 3 of the *Diplococcus pneumoniae* together with an extract of haemolytic and non-haemolytic streptococci. Immunogen was injected as soon as a patient was admitted or as soon as the disease was diagnosed in a patient already in hospital. The dose varied from an initial injection of 5 minims in infants to 10 minims in older children. The injections were usually repeated on alternate days in increasing doses; six injections was the maximum number given in any one case; all were given subcutaneously by nurses; in no case did an abscess form, nor were any ill effects noticed.

From December, 1925, to September, 1926, fifty-five cases of lobar pneumonia and bronchopneumonia were treated without immunogen. From September, 1926, to February, 1927, fifty-six cases were given immunogen, but otherwise were treated in a manner similar to the earlier group.

Cases Treated without Immunogen.

Age.	No. of Cases.	Recovered.		Died.	
		Cases.	Per Cent.	Cases.	Per Cent.
Under 2 years ...	18	7	38.8	11	61.2
Over 2 years ...	37	30	81.0	7	19.0
Totals	55	37	67.2	18	32.7

Cases Treated with Immunogen.

Age.	No. of Cases.	Recovered.		Died.	
		Cases.	Per Cent.	Cases.	Per Cent.
Under 2 years ..	16	10	62.5	6	37.5
Over 2 years ...	40	40	100.0	0	—
Totals	56	50	89.3	6	10.7

The favourable results in the group of cases treated with immunogen were so marked that the records were examined again and cases in which the pneumonia was a terminal condition or had been complicated by some other disease were excluded; but the resulting figures were even more strongly in favour of immunogen, for three of the deaths occurring in infants under 2 years of age who had been treated with immunogen occurred respectively in a marasmic infant, in an infant already moribund at the time of injection, and in an infant who recovered from the pneumonia but who died a few days later from enteritis.

The number of cases is too small to warrant any dogmatic statement, but it would seem that the immunogen had a favourable effect; the duration of the disease did not appear to be shortened, but the mortality rate was reduced.

I wish to thank Lieut.-Colonel P. Macdiarmid, O.B.E., M.D., the medical superintendent of Alder Hey Hospital, for permitting me to publish this note.

ZINC IONIZATION IN THE TREATMENT OF SUPPURATIVE OTITIS MEDIA.

BY

W. E. CROSBIE, M.B., CH.B., D.P.H.,

SENIOR RESIDENT MEDICAL OFFICER, ALDER HEY HOSPITAL, LIVERPOOL.

THE results of the treatment by ionization of chronic suppurative otitis media at Alder Hey Children's Hospital have been so successful that it has been adopted as a routine. Over 300 children have been treated in two years, and nearly all these have been discharged. They ranged in age from 1 to 16 years. In some there was a history of long-standing otorrhoea, and in others the condition developed whilst the patient was in hospital, frequently as a sequel to bronchopneumonia. Otitis is a frequent complication of pneumonia in infants, and explains the cerebral symptoms observed in many cases.

On the occasion of first attendance at the ear clinic a thorough examination is made in order to find out the exact conditions present, with a view to establishing the cause of the chronicity, and Friel's method of classification is followed.

Where otorrhoea is combined with infection of the nose and throat, these complications are first dealt with; if granulations are present an attempt is made to destroy them by electrolysis; if, on the other hand, the case is one of simple tympanic sepsis zinc ionization is instituted.

Method of Treatment.

The object of ionization is to render the tympanic cavity sterile, the method adopted being the passage of an electric current through a solution of zinc, utilizing the coagulation

to detail is absolutely

In order to ensure that the zinc solution comes into immediate contact with the infected walls of the cavity the ear must be thoroughly cleansed, and this is best done by syringing twice daily for a week with a solution of equal parts of potassium chloride, sodium bicarbonate, sodium chloride, and borax. At the end of this period the ear is syringed with sterile water, anaesthetized by a solution of cocaine, as recommended by Dr. F. P. M. Clarke (British Medical Journal, November 20th, 1926, p. 938), and the ionization proceeded with.

The tympanic cavity is filled with the solution zinc sulphate (2 per cent.) and a zinc electrode placed in the meatus and connected to the positive pole. The negative electrode is placed on the leg over a pad of lint soaked in saline. A continuous current, very gradually increased to 3 milliamperes as gauged by the galvanometer, is passed through and controlled by a rheostat.

The average length of treatment is from ten to fifteen minutes, at the end of which period the current is very slowly decreased to zero. The ear is then carefully dried and a little boric powder insufflated.

Applications of the Treatment.

In the treatment of granulations a bipolar electrode composed of zinc is applied directly to them and the current, as described above, passed through. For attic sepsis the cavity is thoroughly syringed, filled with the standard zinc solution, a fine zinc wire electrode is introduced through the perforated tympanic membrane into the attic, and the current passed.

Conclusions.

Zinc ionization has given excellent results, as will be seen from the following table.

Results of Treatment of Chronic Suppurative Otitis Media by Zinc Ionization.

Causes of Suppuration.	Total.	Cured.	Left Hospital.	Referred for Operation	Still under Treatment.

s can frequently be obtained, as their turgidity
ed.

ss to advocate zinc ionization as a cure-all, and
futile to ionize a tympanic cavity if septic foci
he nose, mouth, or throat; in the presence of
e mastoid, ionization is of little service except
rative measure.

r I have classified as cured (as judged by the
tion of the discharge from the ear) may appear
ger than the figures quoted by some other
is influenced by the fact that all patients are

treated as in-patients, and are, consequently, under the best conditions for the prevention of any reinfection.

Careful records of each case are taken, and every endeavour is made to keep in touch with discharged children. Seven have been readmitted with a recurrence of the ear condition, but in each of these it has been evident that after-care has been insufficient.

The best results have been obtained in those cases which have developed otorrhoea whilst in hospital, so that treatment could be commenced within a few days of the onset of the discharge. This would seem to suggest that ionization might be of service in fever hospitals for patients suffering from post-scarlatinal middle-ear infection.

I am indebted to the medical superintendent of Alder Hey Hospital (Dr. P. Macdiarmid) for permission to make use of the statistics obtained in the hospital.

Memoranda;

MEDICAL, SURGICAL, OBSTETRICAL.

A PAROXYSM OF AURICULAR FIBRILLATION CAUSED BY ELECTRIC SHOCK.

THE paper by Professor John Hay and Dr. Wallace Jones on "Trauma as a cause of auricular fibrillation," published in the JOURNAL of March 26th (p. 559), prompts me to put on record the following case.

A man, aged 35, came to consult me in the evening of November 14th, 1926. He stated that during that afternoon, while working in a tunnel, he took hold of a large portable electric lamp which had been temporarily connected with the switch of a motor. He immediately received a shock and was unable to release his hold of the lamp. When the current was cut off by one of his fellow-workmen he fell backwards, but did not apparently lose consciousness. He felt dazed and was conscious of a strange fluttering sensation in his chest. After a rest, however, he was able to resume his job and continued at work for the rest of the afternoon. He walked about a mile and a half to my house, and when I saw him he was not obviously distressed though he complained of feeling shaken, and still felt the fluttering in his chest. There was a small burn on the right thumb. The pulse was quick and irregular, and showed a tendency to a regular recurrence of the irregular beats, which could be spaced, in the manner shown by Lewis, to occur in the irregular pulse which is sometimes associated with auricular flutter. It is possible, therefore, that this was a paroxysm of auricular flutter rather than fibrillation.

Twenty-grain doses of potassium bromide were prescribed and he was advised to go home and stay in bed. When he was seen next morning the pulse was regular and a polygraph curve showed that sinus rhythm was restored at a rate of 66 per minute. No disease of the heart could be detected. The apex beat was in the normal position and the sounds were free from murmur.

I have known this man for many years. He has never had rheumatism. Like at least two others of his family, he has suffered for many years from partial deafness associated with nasal obstruction, but apart from this he enjoys good health.

Hull. E. E. LASLETT, M.D.Vict.

RUPTURE OF THE RECTUS ABDOMINIS MUSCLE.

IN the JOURNAL for April 30th Mr. P. J. Moir and Mr. C. R. McCash describe interesting cases of rupture of the rectus abdominis muscle occurring in healthy persons during severe physical effort. The following case furnishes still another example, and may also be of some interest.

On July 22nd, 1917, an ambulance attendant was, with one assistant, carrying a very heavy patient on a stretcher up a difficult staircase in a nursing home, when he felt a tearing pain in the right side of his abdomen. He struggled through his work during the next two days, but was then forced by increasing discomfort to enter the Glasgow Western Infirmary.

Examination revealed a slight swelling over the right rectus muscle, and this area was exquisitely tender. There was no ecchymosis. On operating I found that the sheath of the right rectus was intact, but on opening this I saw at once that the muscle, except at its medial and lateral borders, was torn across. The gap between the retracted torn fibres was filled with blood clot. The level of the injury was about two inches below the umbilicus. Muscle and sheath were sutured, and the wound closed. The patient has been at work continuously since his dismissal from hospital.

Glasgow. CHARLES BENNETT, M.B.

LOCAL ANAESTHESIA IN SUBMUCOUS RESECTION OF THE NASAL SEPTUM.

THAT a local anaesthetic method, such as that of McKenzie, ought to be more widely known is evident from the fact that the operation is still performed under general anaesthesia in certain centres. General anaesthesia causes more haemorrhage, makes the operation more difficult, and is more dangerous.

The following points may be added to Dr. Sturm's excellent account of Dr. Dan McKenzie's local anaesthetic method.[1]

1. Anaesthesia is improved if particular care is taken to apply the cocaine and adrenaline to the mucosa overlying the spheno-palatine ganglion, an area situated just behind and above the posterior end of the middle turbinal.

2. In cases where the anterior edge of the quadrilateral cartilage is dislocated the usual application of cocaine and adrenaline to the mucosa of the nose should be supplemented by an injection of novocain and adrenaline into the skin covering the anterior edge of the displaced cartilage.

3. The quantity of cocaine (3 grains) advocated by Dr. Sturm may be largely exceeded without any ill effects.

4. Hospital patients may go home the same day, to return the following morning; the packing is then removed and is not replaced.

Manchester. B. McKELVIE, M.B., F.R.C.S.Ed.

PEDUNCULATED SUBMUCOUS FIBROMYOMA OF THE STOMACH.

THE following details of a case of submucous gastric fibromyoma, which at first was thought to be gastric ulcer, seems to be worthy of record.

An unmarried woman, aged 32, well developed, of mixed European, African, and Burman descent, had had good health until November 27th, 1924, when she felt tired and giddy and passed tarry stools. The family history was good, with the exception that her mother had died at the age of 48 from cancer of the stomach. There was no vomiting or abdominal discomfort of any kind. By the beginning of June, 1925, she had recovered entirely and remained well until the beginning of February, 1926, when she again felt tired and ill and passed dark stools. On February 13th, the abdomen was heavily kneaded, which is the Burmese panacea for all abdominal troubles; soon after this the patient vomited a considerable quantity of blood. When admitted to hospital on February 17th, 1926, her condition was bad. She was intensely anaemic, the face and ankles were oedematous, the temperature 101°, pulse 150 and feeble, and respirations 26. The case was diagnosed as bleeding gastric ulcer, and medical treatment was given, the temperature continuing to range between 100° and 101°. Three days later she developed parotitis which cleared up with fomentations, and on February 23rd her blood gave a positive Widal reaction in a dilution of 1 in 80. She was then treated as a case of enteric fever complicated by gastric ulcer. The temperature returned to normal on March 3rd, the anaemia slowly disappeared, and the patient was discharged from hospital on April 6th, 1926.

Five months later the patient was again suffering from haemoptysis and passing tarry stools; she stated that the trouble had returned on August 20th. On admission to hospital her condition was good, the temperature normal, the pulse 84, there was no pain or tenderness of any kind, but she was very anaemic. One morning a small movable tumour was felt in the epigastric region, which disappeared suddenly, and was not detected again. She continued to pass blood in the stools, and on September 9th a test meal showed that the free and total acids were normal; *x*-ray photographs indicated a distinct tumour at the upper end of the lesser curvature.

On the following day she was given scopolamine, morphine, and spinal anaesthesia with stovaine, local anaesthesia with novocain, and a few whiffs of A.C.E mixture. The abdomen was opened by an incision extending from the ensiform cartilage to the umbilicus, and a freely movable pedunculated tumour was found high up, attached to the lesser curvature of the stomach. As it was difficult to reach the attachment of the tumour from outside the stomach an opening was made over the lower part of the tumour and the pedicle was separated from the stomach wall on the inside. Several bleeding vessels were tied, and, since the haemorrhage continued, a silk purse-string suture was tied round the raw areas. The size of the tumour was 6 by 4½ by 4 cm., and the area of its attachment was about 3 by 2½ cm.

Lieut.-Colonel J. Taylor, director of the Pasteur Institute, Rangoon, reported that the tumour was a fibromyoma. The patient made an uninterrupted recovery.

Reports of Societies.

THE USE OF FASCIAL GRAFTS IN HERNIA.

AT a meeting of the Devon and Exeter Medico-Chirurgical Society on April 21st, with Dr. R. EAGER in the chair, the President, Mr. A. L. CANDLER, read a short explanatory paper on the subject of the use of fascial grafts in the repair of ventral and inguinal hernia.

Mr. Candler quoted extracts from the paper by Gallie and Le Mesurier in the *British Journal of Surgery*, October, 1924, and lantern slides of the illustrations in this article were also exhibited. Mr. Candler showed four patients who had been so treated. The first was a man, aged 47, who for eight years had had a ventral hernia as big as a football, following gangrene of the abdominal wall after appendicectomy and drainage. A graft composed of three strands of fascia had been inserted in 1926 with good results. A lad aged 17 had been operated on in 1923 for a left obturator hernia, the pelvis being full of pus and adhesions. After drainage of the cavity the abdominal wall had become gangrenous, and there had resulted a large ventral hernia, with a gap four inches wide, in the aponeurosis. In 1925 this gap was closed with fascial sutures, the peritoneum being repaired with catgut. The patient had been able to work as a farm labourer since this operation. A man, aged 40, had been operated upon two months previously for the repair of the posterior wall of the inguinal canal by fascial sutures. There had been a recurrence of the hernia for which the ordinary radical cure operation had been performed in 1921. The last patient was a man who had received a bayonet wound in the left iliac region during the war with a resulting large ventral hernia, which had recurred at varying intervals after three operations for repair. A fourth operation had been performed in December, 1926, for repair by fascial sutures, but suppuration in the wound had led to an unsatisfactory result.

Dr. SHAW showed a woman, aged 35, who had had an operation for appendix abscess in 1913. A ventral hernia resulted, for which repair was attempted in 1916, and again in 1919. After a further recurrence the gap was once more closed in December, 1926, four strips of fascia lata being grafted for this purpose. At the present time the wound appeared to be quite sound and the result of the operation was most satisfactory. Dr. Shaw remarked that the case was a good illustration of the value of "living suture repair." At the operation a definite gap was found which was surrounded by a hard scar, and bridged over by the thinnest areolar tissue. Fascial grafts were used to make a "darn" filling in the space, the sutures being carried through the hard edges.

Mr. WAYLAND SMITH showed a man, aged 46, who had had a left inguinal hernia for over thirty years. When first seen there was a scrotal hernia "the size of a pint mug," and an inguinal ring admitting three fingers. He came to hospital because the hernia was increasing in size and becoming painful. In May, 1926, the hernia was operated upon, and the inguinal canal repaired with four strips of fascia lata. The patient had restarted work as a gardener two months after the operation, although advised further rest. There had, however, been no recurrence. Mr. Wayland Smith also showed a woman, aged 46, who had developed a ventral hernia and wide separation of the recti after childbirth five years previously. Excision of the hernal sac and the stretched linea alba was performed in August, 1926. A new linea alba had been constructed by suturing the cut edge of the sheath of the anterior rectus muscle with five strips of fascia lata.

Clinical Cases.

Dr. R. N. CRAIG showed a woman, aged 54, whose condition had been diagnosed as Charcot's disease. During the past six years a gradual deformity of the left knee and right ankle had developed. The pupils were equal but did not react to light; the reaction to accommodation was,

...disturbance of sensation. The ...reactions of the blood and the cerebro-spinal fluid were negative. The luetic reaction of the cerebro-spinal fluid with colloidal gold was positive. A radiogram showed subluxation and complete disorganization of the left knee-joint with massive proliferation of bone. An unusual feature was the presence of pain in the left knee; this had diminished under a full course of salvarsan.

Dr. Craig also showed a boy, aged 2½, born with hydrocephalus which had slowly progressed. Double optic neuritis had developed, sufficiently intense to cause apparently complete blindness. He had been under treatment from October, 1925, and for a year and three months lumbar puncture had been employed every week. After this it had been performed in alternate weeks, and it was now only necessary once in three weeks. Twelve months ago the head circumference had been 22 inches; it was now 22½ inches, and the child was able to talk intelligibly. The eyesight had improved sufficiently for him to pick up twelve pins from off the floor on one occasion—which he proceeded to swallow one by one! The diminution in the head circumference, Dr. Craig said, had been carefully checked, and the most interesting feature in the case was the undoubted improvement in mentality since the lumbar punctures had been started. It had been found that the child on each occasion stood well the withdrawal of 40 c.cm. of cerebro-spinal fluid, after which vomiting of the cerebral type would begin, lasting for six or seven minutes. In his opinion the repeated withdrawal of cerebro-spinal fluid encouraged atrophic changes in the choroid plexus, and so led to cessation of a hypersecretion. The possibilty of free withdrawal of this fluid clearly showed that the hydrocephalus was not of the obstructive type; a total of two and a half pints had been removed.

Dr. R. Eager described some cases of hydrocephalus with very large increase in head circumference seen in mental hospital practice.

Dr. Gordon showed a man, aged 62, suffering from lead palsy; he had been a painter all his life. For a month before admission to hospital he had had intense colic and vomiting, with progressive tremor weakness of the hands, anorexia, and anaemia. A blue line was noted on the gums and wrist-drop on the right side. The blood pressure was ow 170/110. There was weakness and slight wrist-drop th inability to extend the third and fourth fingers. The e line had disappeared from the gums and the pallor s less marked than formerly. Treatment had consisted giving magnesium sulphate and potassium iodide daily the mouth; seven teeth had been extracted on account ral sepsis.

. Craig showed a middle-aged woman with dysphagia, ght to be functional in origin. Some fullness of the below the chin had recently shown itself, but no te tumour could, however, be felt. The patient had o pounds in weight each week for the past three

Mr. Worthington said he had made a laryngo-examination of Dr. Craig's patient and could find no ality except that the larynx appeared to be somehed forward. He recommended oesophagoscopy in exclude the possibility of a post-cricoid growth.

ock showed a child, aged 6 months, with a cystic th, and had increased in size more rapidly in the under the left lower jaw which had been present weeks. It was thought probably to be a cystic He said that an operation would probably be n in the near future, and agreed that it was icroscopic section that a definite diagnosis could

Mr. Worthington described the difficulty of on similar tumours, which had proved to be ysts. Dr. Solly drew attention to the modern in relation to endotheliomata, and said that these ere epithelial and not endothelial in origin. owed also a series of pathological specimens: a endothelioma of the submaxillary gland; a cystic adenoma of the uterine mucosa; a section of the breast secondary to chronic lobular onic cystic mastitis; and a glandular celled the ovary.

Reviews.

FUNDAMENTALS OF THE ART OF SURGERY.

Surgical literature nowadays consists in the main o... didactic textbooks, of articles in journals varying muc... in originality and purpose, and of highly technical mono... graphs, which seem to be growing in popularity, especially... in America. It is, therefore, rather a pleasant relief to come across a book of less stereotyped character, such as the *Fundamentals of the Art of Surgery*,[1] by Mr. John H. Watson of Burnley. The author is an idealist, and has much to say which is of interest to the younger practitioners in the larger provincial towns, who are desirous of entering upon a surgical career. He would impose on them a very high standard "in the pursuit of an adventurous and exacting craft," and supports his opinion by a quotation from Abernethy, who said that "the hospital is the only proper college in which to rear a true disciple of Aesculapius." He lays stress on the fact that surgical operations, when performed by competent surgeons, seem so simple that anyone with a dexterous pair of hands is tempted to undertake them. Important as it is to be equipped with the necessary operative and technical skill, it is still more important to have the foresight to know when and under what conditions an operation is best performed, and the experience and ability to conduct the case safely through the post-operative period. In his preface the author says "the more one sees of practical surgery the more one is impressed by the relative frequency of unforeseen complications, and when one carefully thinks out the cause of these troubles it is only to find that most of them could be prevented. Unfortunate accidents occur to every surgeon—and they are less likely to happen in the practice of the surgeon who has judgement, skill, and experience."

Mr. Watson emphasizes the importance of the part the general practitioner must play if surgical work is to be successful. Upon him devolves the responsibility of making first examinations, of sounding the note of warning, of advising operative intervention, and seeing that no important detail of preparation or treatment is neglected, the omission of which might prejudice the recovery of the patient. The contents of this book deal with the problems, both in thought and action, that are ever presenting themselves to the busy operating surgeon. It pays graceful tribute to the masters of the art, and each chapter is introduced by an apt quotation from their legacies in literature. The first chapter rejects the notion that the good surgeon is born, not made, holding that he is produced by work, study, and conscience. Mr. Watson, indeed, expresses an instinctive fear of the "clever manipulator" or so-called "brilliant surgeon"; the majority of the textbooks, he thinks, are misleading, in that they are written in simple style for examination purposes, and do not describe the varied and numerous complications met with in the operations of importance and the dangers thus involved. Surgery, he says, "is made easy for the sons of Aesculapius to take too much on them." On surgical efficiency he expresses strong views, and asserts that to become a useful surgeon a man ought to spend, after qualifying, at least twelve to eighteen months as a resident, and three years as an assistant to a surgeon, and publish the work he has done; only when this method is adopted, as it is by the American College of Surgeons, will it be possible to prevent a great deal of promiscuous and harmful surgery. Young surgeons in this country, he asserts, are at a great disadvantage compared with American and Continental surgeons, who possess much greater facilities for doing research on animals. The chapter on surgical judgement is full of sound advice. The surgeon requires a long time to develop his reasoning powers and mental habits, and no written instructions can educate him; he must be master of the ancillary sciences, and realize his own limitations. The rest of the book is of more routine

[1] *Fundamentals of the Art of Surgery.* By John H. Watson, M.B., B.S.Lond., F.R.C.S.Eng. London: W. Heinemann (Medical Books), Ltd. 1926. (Demy 8vo, pp. x + 369; 65 figures. 17s. 6d. net.)

character, containing chapters on case-taking, preparation of the patient, anaesthesia, sepsis and antisepsis, technique, incisions, shock, wounds, post-operative treatment, and complications. The chapters on prognosis and complications would have been improved by the quotation of individual cases.

The book is an excellent piece of work, and is to be recommended to all who are interested in and practise surgery. It deals with the whole subject in an idealistic and humane way. It sets a high standard, which, however, can be achieved, but leaves the impression that all is not well with surgery, outside the bigger hospitals at any rate. It owes much of its value to the fact that it is written by a surgeon practising in a town of moderate size. His opinions may not be palatable to all surgeons, but he deserves all the more praise for having the courage to express them so frankly.

CANCER FROM THE CLINICAL POINT OF VIEW.

THERE is no doubt that the busy practitioner is as keenly interested in the "cancer problem" as the pure pathologist; but it is with cancer itself, rather than with the problem, that he is more immediately concerned. He will, therefore, probably approve of two books on cancer published recently in France, in which the cancer problem is not mentioned—one by MAURICE RENAUD,[2] the other by HENRI HARTMANN.[3]

Renaud defines the position of the practitioner very clearly: Cancer can be studied from a number of different standpoints; biologists, histologists, therapeutists, sociologists have their special doctrinal conceptions, the interest of which is theoretical and leads to more or less brilliant, but useless, hypotheses. What a doctor requires in practice is a precise knowledge of what is actually known about cancer. Renaud has brought together essential and well established facts relating to cancerous new growths, the stages of their development, the mechanism of the accidents and complications to which they give rise, and the clinical pictures they exhibit; he has omitted everything that does not come within this purview. His study is not of cancer in the abstract, but of cancer in the patient. Cancerous new growths have their own characteristic features and natural history, but from the point of view of the practitioner there is little that is specific in their manifestation, and their clinical history reduces itself in the main to that of the complications which they provoke. After giving a general account of the anatomical characters of cancer and its modes of extension, Renaud describes the local complications due to pressure, ulceration, and infection, and the effect on the function of the affected organ resulting from its partial destruction. An interesting instance of the tolerance exhibited by the lungs to the presence of cancerous growths is mentioned. A soldier, aged 22, in full health and activity, was suddenly seized with symptoms of mediastinal compression, and died in a few days with compression of the superior vena cava. The right lung was a solid mass of primary carcinoma, which had remained latent to within a few days of death. The greater part of the book is devoted to the distant complications of cancer, the several functional systems being considered, with separate chapters on the reactions of the fluids of the body and on infection. For instance, the question of nephritis in cancer is discussed. Renaud considers that in the more advanced stages of the disease the renal function is often affected and that an insidious uraemia develops, which is an essential factor in the production of the cancerous cachexia.

Hartmann's book, which is written in collaboration with a number of specialists on cancer of particular organs, deals with diagnosis. Its object is to give a concise statement of the early signs of cancer, for the use of practitioners. The old complaint reappears in the preface, that frequently cases are sent for surgical treatment too late to give any hope of cure. There is no doubt of the correctness of the diagnosis in such cases, only it should have been made earlier to have been of practical value. It may be hoped that Hartmann's concise notes on the characteristic signs of early cancer in the different organs may assist in reaching earlier diagnoses. It is not merely a question of diagnosis, however. Under the heading of cancer of the rectum, for instance, we find this statement: Many patients who complain of a discharge of blood from the anus, with repeated liquid stools, are treated for months for haemorrhoids or colitis, when a simple rectal examination would have immediately established the diagnosis of cancer. It has been said that more errors arise from lack of examination than from lack of skill in diagnosis.

TUBERCULOSIS OF THE LUNGS.

IN spite of the mixed praise and blame recently meted out so copiously to the general practitioner, there is still no dearth of writers concerned with his intellectual welfare. DRS. HYSLOP THOMSON and A. P. FORD with their *Tuberculosis of the Lungs*[4] have added yet another to the numerous manuals already existing on the diagnosis and treatment of pulmonary tuberculosis. Apart from Chapters III and IV, to which exception can be taken on a number of grounds, the book seems to differ very little from many of its predecessors. As an example of the inexact type of statement in these chapters the following sentences may be quoted:

> "In children root tuberculosis is usually associated with infection of the cervical lymphatic glands, which is frequently due to the bovine type of bacillus. In Mitchell's series of 72 cases of tuberculosis of the cervical glands, the bovine tubercle bacillus was present in 90 per cent. It is probable, therefore, that in most types of root tuberculosis in children the infection is of bovine origin."

This last inference appears to be wholly unjustifiable. If the writers had been acquainted with the conclusions of the Royal Commission on Tuberculosis they would have known that one of the strongest arguments in favour of the respiratory route of infection in pulmonary tuberculosis is the fact that though the bovine bacillus is found in a large proportion of cases of cervical and mesenteric glandular tuberculosis, tuberculous lesions of the bronchial glands are almost invariably due to the human type of bacillus, indicating that the bronchial glands are infected; not from the alimentary, but from the respiratory tract. Apart, however, from the discussion on the causes and the morbid anatomy of tuberculosis, the book appears to be quite sound, and should appeal to those who are desirous of a dogmatic, rather than a scientific, presentation of our knowledge of pulmonary tuberculosis.

IN *Compression of the Lung in the Treatment of Pulmonary Lesions*[5] Dr. STUART TIDEY reiterates the views he has several times expressed on the value of external compression of the chest wall in the treatment of tuberculous and other diseases of the lungs. His main contention is that relaxation of the peripheral pull on diseased areas is the essential element in the healing of pulmonary lesions. To effect this he advocates strapping the chest from below upwards so as to crowd the lung into the upper and narrower portion of the thoracic cavity, where it will be correspondingly constricted. The application of apical splints is, he considers, bound to be unsatisfactory, since the lung, instead of being constricted, will be forced downwards into a wider part of the thoracic cavity and will therefore be free to expand more than before. On mechanical principles this argument appears satisfactory, but whether the actual results are the same as those theoretically assumed it does not seem possible to say. The point could be decided no doubt by x-ray examination of the chest; unfortunately Dr. Tidey does not appear to have controlled his procedure by this method. Several of the arguments that he advances in favour of external compression as opposed to internal compression by the introduction of gas or oil into the thoracic cavity are unsound.

[4] *Tuberculosis of the Lungs.* By H. Hyslop Thomson, M.D., D.P.H., and A. P. Ford, M.R.C.S., L.R.C.P., D.P.H. London: Baillière, Tindall and Cox. 1927. (Demy 8vo, pp. x + 179; 20 figures. 10s. 6d. net.)

[5] *Compression of the Lung in the Treatment of Pulmonary Lesions.* By Stuart Tidey, M.D.Lond., M.R.C.P.Lond. Oxford Medical Publications. London: Milford, Oxford University Press. 1927. (Extra post 8vo, pp. xiv + 86. 3s. 6d. net.)

He states, for example, that artificial pneumothorax cannot be applied when both lungs are diseased, or when fibrous adhesions to the chest wall are present. Further, he appears to be unacquainted with the selective effect of internal compression on locally diseased areas of the lung. There is little doubt, however, that the method he advocates is well worth adopting in early cases of tuberculosis before recourse is made, if necessary, to the more radical method of treatment introduced by Forlanini.

The first volume of BLÜMEL'S book on the control of tuberculosis was reviewed on July 10th, 1926 (p. 65). The second volume,[6] which has now appeared, is of equal interest and should appeal to a wide circle of readers. In all it contains forty-three articles by different authors on the prophylaxis and treatment of tuberculosis. Most of these deal, not with the management of individual cases, but with the measures used in practice for the eradication of the disease as a social scourge. Thus the relationship between occupation, social status, housing conditions, and tuberculosis; the planning, erection, and conduct of sanatoriums; propaganda in the schools; education of the medical student and of the general practitioner; courses for those engaged in the tuberculosis service; and the general organization and administration of diagnostic and treatment centres are all taken into consideration. Statistics are given of the results obtained by different workers in the use of artificial pneumothorax, showing how even unpromising cases of the exudative type may receive great benefit and may live useful lives for some years. Finally, there are a number of contributions describing the organization of the tuberculosis campaign in different countries. The whole work is of a high standard, and compiled with that attention to care and thoroughness which is characteristic of the better kind of German book.

PNEUMOCONIOSIS.

In spite of their engagingly modest method of expressing their claims, the two radiologists Professor H. K. PANCOAST and Dr. E. P. PENDERGRASS of the University of Pennsylvania are more than justified in bringing out their well illustrated work on *Pneumoconiosis (Silicosis): A Roentgenological Study, with Notes on Pathology*,[7] for they have had extensive experience of examining cases in America, and have made a critical survey of the literature. Although silicosis is the important factor in the production of serious lung lesions in pneumoconiosis, and is responsible for the damage in the occupational diseases spoken of as anthracosis, siderosis, and chalicosis, and though the authors were at one time inclined to substitute silicosis as an inclusive title, they decided to retain pneumoconiosis, as there may be other agents besides silica that produce the morbid changes of pneumoconiosis.

The importance of skiagraphy in arriving at a diagnosis, on which Dr. Watkins-Pitchford, chairman of the South African Miners' Phthisis Bureau, insisted, is endorsed, and a feature of the authors' book is the series of well selected skiagrams of the chest in the three stages of the disease. The detailed descriptions of these stages, as revealed by x-ray examination, are correlated with the pathological changes, of which a good summary is given in a separate section with full acknowledgements to Dr. A. Mavrogordato. The nature of the "dust cells" which give rise to the fibrosis, the blocking of the lymphatics, and the complication of tuberculous infection are described. In a special chapter the various occupations, such as in the different kinds of mines, granite cutting, pottery, metal grinding, cement, brick, and asbestos workers, are passed in review.

There is a short section on prevention, but, as already suggested, the most valuable part of the book, which only incidentally deals with the ordinary clinical signs and symptoms, is the diagnosis by skiagraphy.

ORTHOPAEDIC NURSING.

THE spread of the movement for the care near the places where they dwell, and the of many local clinics, which can be visited by surgeons only at considerable intervals, ha responsibilities upon specially trained sisters It is therefore well that a small handbook[8] sh duced for the guidance of probationers, nurses It is described as a textbook, but we are gla to say that it has the merits of simplicity so that its size excludes it from the ranks pretentious textbooks.

It may be thought that a handbook of whi are vouched for by such distinguished authc Robert Jones and Dame Agnes Hunt need mendation by us, but nevertheless some note o may be useful.

Miss EVELYN C. PEARCE is well fitted to a guide by a long course of training in t Liverpool and Oswestry, and by the tenure of teacher of medical gymnastics at Oswestry Hospital; she may therefore be trusted to mature views of her distinguished sponsors a results of her own experience.

A short "foreword" is contributed by Sir and the introductory chapter is written by Hunt; in it, with characteristic vigour and c urges her readers not to be satisfied with hacks, but to strive to be apostles of the gosp in its widest sense and to go forth and inc methods of care of children, whether crip upon parents and the world at large, thu prevent as well as to cure.

It is obvious that such work requires fre paedic nurse the exercise of great tact if are to follow and if mothers are not to resent of the nurse into what they regard as thei of discipline and training. The book is eight chapters, in which the subjects of anato deformities, flat-foot and claw-foot, paral tubercle, and deformities of the spinal colu dealt with, and the making and application Paris and of other splints are described. It great practical use to those for whom it has b

NOTES ON BOOKS.

We have so recently had occasion to refer Heath's *Minor Surgery and Bandaging*,[9] edited b WILLIAMS, that the appearance of a new edit opportunity for further comment. That the b its nineteenth edition is sufficient evidence that it has had on its readers during the last sixty-s no sign of abating. What those of us who ha of knowing and listening to Christopher Hea the editorship of his book is that it shall be a than is necessary to bring the subject-matter u that incongruities shall be avoided. In these Gwynne Williams has shown himself to be a g is not often that a book can boast of exhibit vitality in the third generation: the explanation instance doubtless is that *Minor Surgery* dates f of great teachers, among whom Christopher He the most distinguished.

MUIR'S *Bacteriological Atlas*[10] is a small, beautifully got up, and should prove a use companion to the student in his bacteriologica plates were originally drawn to illu features of the various pathogenic in class-teaching, and as they were assistance it was suggested that they should be so made available to a wider circle of students. to the various textbooks on bacteriology. Th doubt that they will serve this purpose a

coloured plates, sixty in number, are well reproduced from Dr. Muir's own excellent paintings, and they therefore bring out the particular features of the various micro-organisms with great clearness, accuracy, and completeness. A few short paragraphs of text are placed beside each plate by way of description and to draw attention to special points. We have no doubt the book will be well received.

Little Mothers and Big Sisters[11] is the title of an elementary textbook for senior schoolgirls written by Dr. HILDA HALLIDAY. Its aim is to arouse in the "big sisters" a sense of the importance of the mind in their younger brothers and sisters. Not only, they are told, is it sufficient to know how to dress, bathe, and generally take care of the bodies of the young ones, but their minds must early be taught self-discipline, and they must be helped to cultivate the habit of enjoying all good things. The little manual is warmly commended by Professor Kenwood in an introductory note. It is clearly and simply written, the print is good, and it is aptly illustrated by reproductions of five well known masterpieces. It deserves to be widely read.

[11] *Little Mothers and Big Sisters.* By Hilda Halliday, M.R.C.S., L.R.C.P., D.P.H. With an introduction by Henry R. Kenwood, C.M.G., M.B., F.R.S.E. London: Milford, Oxford University Press. 1926. (Cr. 8vo, pp. xvi + 79; 5 illustrations. 1s. 3d. net.)

PREPARATIONS AND APPLIANCES.

A Simple Spreader for Making Blood Films.

DR. W. E. COOKE (Wigan) has designed a simple spreader for blood slides, by means of which the preparation of blood films can be undertaken successfully even by novices. The spreader is a piece of glass measuring 5 cm. by 19 mm., the edges of which are very finely ground and square. A drop of blood the size of a large pinhead is placed at the end of a glass slide; the spreader is held at an angle of approximately forty-five degrees to the slide and moved backwards until it touches the drop; the motion is then reversed, the spreader drawing the blood behind it and distributing it evenly in the centre of the slide. The great advantage is that the blood does not spread to the edges of the slide, causing most of the leucocytes to be lost. The spreader is made by Messrs. Watson and Son, 313, High Holborn, W.C.2.

Ephedrine Hydrochloride.

In addition to "tabloid" *ephedrine hydrochloride 1/2 grain*, Messrs. Burroughs Wellcome and Co. are now supplying "hypoloid" ephedrine hydrochloride 0.03 gram (1/2 grain approximately) for hypodermic injection. It is issued in boxes of ten 1 c.cm. phials.

SIXTH BRITISH CONGRESS OF OBSTETRICS AND GYNAECOLOGY.

(Concluded from p. 884.)

RECURRENT PREGNANCY TOXAEMIA.

DR. JAMES YOUNG (Edinburgh) read a communication on recurrent pregnancy toxaemia. He believed that patients with this condition afforded evidence in support of the view which he had advanced in 1914 that the eclamptic toxaemia was caused by massive degeneration of the placenta. In 47 successive cases of eclampsia at the Royal Maternity Hospital, Edinburgh, toxaemia occurred in previous or subsequent pregnancies in 15 or 31.9 per cent., while in 21, or 44.7 per cent., there was recurrent toxaemia or an unbroken sequence of abortion, premature birth, stillbirth, or accidental haemorrhage. It had been discovered that in cases of abortion or accidental haemorrhage occurring in the sequence of vitiated pregnancies there might be no toxaemia. In 118 cases of "albuminuria" there was recurrence of toxaemia or of abortion in 42, or 35.6 per cent., and here again in some of the abortions there might be no toxaemia. The same observations were made in the case of accidental haemorrhage. Dr. Young stated that in all the cases, whether toxaemic or non-toxaemic, there was clear evidence that the cause of the pregnancy morbidity was degenerative change in the placenta. This must, therefore, be looked upon as a condition precedent to the toxaemia and not, as had commonly been thought, as a condition which occurred in consequence of the toxic process. These findings indicated that attention must be directed to the factors which tended to produce damage of the placenta in order to discover the causes of late pregnancy toxaemia. The toxic process which might develop in such cases was to be looked upon as an incidental occurrence. It was more likely to supervene if the damage, while involving a large area of tissue, was yet insufficient to cause immediate ending of pregnancy, and a large mass of degenerating tissue was retained in the uterus in intimate relation with the maternal circulation. Dr. Young added that these discoveries suggested the need for a revision of the classification of the late pregnancy toxaemias. They tended to show that the cases of recurrent eclampsia and recurrent "albuminuria" had a similar origin.

RADIUM TREATMENT OF CARCINOMA OF THE CERVIX.

Dr. G. I. STRACHAN (Cardiff) read a paper on further experience with radium in the treatment of carcinoma of the cervix. He stated that radium had been used in Cardiff since 1922, and that all the cases where it had been used were inoperable; 150 to 170 mg. of radium had been placed in and around the cervix for twenty-four hours, and no additional benefit had followed its application for longer periods. He advocated vaginal douching for some time before and after the use of radium, exploration of the uterine cavity to ensure the absence of pyometra, and an *x*-ray examination after insertion of the tubes to ascertain whether they were in good position. He emphasized the importance of not curetting the growth before insertion of the tubes. As contraindications to radium, he mentioned severe anaemia, foul sloughing carcinoma, pyometra, inflamed appendages, and fistulae. He stated that 97 patients had been treated. Of these, 33 were still alive, one after five years, 39 had died, and 25 could not be traced. Even in cases where there had not been cure, the amelioration in the patients' condition had been very great, and he thought that with improved technique the proportion of cures might be increased.

Mr. COMYNS BERKELEY (London) said he had first used radium treatment for carcinoma of the cervix in 1912. He had only had two cures in twelve to fourteen years. He was now using Voiselle's method, but had completely failed to obtain such brilliant results, though his technique had been exactly the same.

PATHOLOGICAL FORMS OF THE CORPUS LUTEUM.

Sir EWAN J. MACLEAN presided over the session on April 29th, which Dr. WILFRED SHAW (London) opened with a paper on some pathological forms of the corpus luteum.

Dr. Shaw referred to the classification of abnormal forms of the corpus luteum by Novák and De Linde as being too complicated, and omitting the most interesting pathological group—namely, the tarry cysts. As regards inflammatory forms of the corpus luteum he found haematomata common; in these patients there was always an increase in size in the lutein cells which might account for the menorrhagia common in these cases. He drew attention to certain tarry cysts of the Graafian follicle which superficially resembled endometriomata. These cysts could not be distinguished macroscopically from Sampson's cysts, but they arose from Graafian follicles and contained lutein cells in their walls, though these lutein cells were always abnormal. There were three closely allied types with a common origin, and he thought the reason for this was that the stimulus producing them attacked the follicle at various phases of its life-history. A characteristic feature was that they had an epithelial lining, which was derived from the endothelial lining of the capillaries. Rupture of these cysts led to implantation of lutein cells on to other sites in the peritoneal cavity. He had found lutein cells in these cases on the surface of the ovary, in the utero-vesical pouch, and even on the appendix.

Dr. J. W. A. HUNTER (Manchester) asked whether it was implied that all tarry ovarian cysts arose in this way from the corpus luteum, and that there was no endometrial origin in certain cases, as had been suggested by Sampson. Dr. WILFRED SHAW, in reply, said that he still doubted the soundness of Sampson's theory. He had not been able to demonstrate an endometrial origin in these cysts, but had been able to account for them in the way described.

CARDIAC DISEASE IN PREGNANCY.

Dr. R. A. LENNIE (Glasgow), in a paper on cardiac disease in pregnancy, considered the relation between various cardiac lesions, the parity of the patients, and the stage of pregnancy at which compensation broke down. He had collected eighty-six cases treated during the past

primiparae than in multiparae, and that such loss in compensation was most liable to occur after mid-term in primiparae and before it in other cases. From analysis of his figures he found the best results had been obtained by Caesarean section and sterilization at term, or during pregnancy, or by hysterectomy. Chloroform had been the anaesthetic in all cases, and had proved perfectly safe.

Dr. GEDDES advocated Caesarean section under spinal anaesthesia as the quickest and safest method of delivery; it might be supplemented by gas and oxygen. He emphasized the danger of fatal bronchitis after respiratory anaesthetics. Professor LOWRY (Belfast) urged the importance of co-operation with the physician in these cases, and of having a cardiac clinic in the ante-natal department. He thought chloroform anaesthesia or any such patients. Dr. SOLOMONS (Dublin) preferred scopolaform of vaginal Caesarean section with spinal anaesthesia. mine-morphine narcosis combined with spinal anaesthesia. He had seen cases where there had been no relief after Caesarean section and where death had occurred several days later. Dr. HENDRY (Glasgow) protested against indiscriminate Caesarean section and thought that the danger of normal delivery had been exaggerated.

THE CARE OF NEW-BORN CHILDREN.

Dr. NORMAN CAPON (Liverpool), in a paper on the relation of the obstetrician to the pediatrician, suggested ways in which the health of the new-born child might be improved by co-operation between obstetricians and pediatricians. He lamented the fact that the care of new-born children was in most hospitals relegated to nurses. During the early weeks of life nurses were usually found to be self-appointed baby specialists. He pointed out that a medical opinion could only be based on anatomy, physiology, and pathology, and as regards the new-born this was only just beginning to be realized by the obstetrician. He hoped that the future would see the obstetrician and pediatrician working more closely together.

Dr. W. FLETCHER SHAW said that since 1904 a pediatrician had been a member of the staff of St. Mary's Hospitals, Manchester, and also lecturer in diseases of children. The care of the new-born and the teaching of nurses and students in the care of the new-born was in his hands. Dr. SOLOMONS (Dublin) agreed with Dr. Capon, and thought that the Manchester school was far ahead of that in regard to co-operation between obstetrician and pediatrician.

DIPHTHERIA AND ITS PREVENTION.

REPORT TO THE MEDICAL RESEARCH COUNCIL.

FORMATION on the Schick test and active immunization employed in the control of diphtheria, on the incidence mortality of the disease in Great Britain, and on the active work which has been done in this country, the United States and elsewhere, is contained in the report J. Graham Forbes, originally written for the London Council, and published now as one of its series of reports by the Medical Research Council.

rapid decline of the case mortality rate of diphtheria on, which fell during the years immediately succeed- introduction of antitoxin treatment from 30 to 10 , is shown by figures quoted in the report to have slow down. Side by side with this retarded rate , which is not confined to London, there has been a tendency in London and some of the great an increase alike in the general attack rate of and its death rate per 1,000. For the metroroughs, arranged in five classes, a coincidence ed between density of population per acre, g in rooms, and the diphtheria attack rate. e lowest in these respects, which comprises the ich, and Lewisham, has 24.9 persons per acre, overcrowding of 6.4, and a diphtheria attack For Group E, which is the highest and which rpney, Shoreditch, Southwark, and Bethnal rresponding figures are 161.7, 28, and 35.8. greater liability

IMMUNIZATION.

warning, however, is entered against the assumption th this coincidence necessarily implies causation. Diphther prevalence among close-quartered families may be held i check by the "herd" immunity, induced by minima doses of infection, or, on the other hand, increased in shifting population by the influx of newcomers, who not only lower numerically the resistance of the "herd," but raise the virulence of the infective organism.

The survey of Schick-testing and active immunization, as carried on in Great Britain from 1921 to 1926, is informative in a high degree. Excepting in fever hospitals, where the Schick test was applied to a number of patients for what may be described as administrative reasons, Schick-testing and immunization appear, with some other exceptions, to have proceeded collaterally. The immunization figures will be quoted.

In England and Wales there was in London community immunization in Holborn, Westminster, and Camberwell, and in the provinces, in eight areas, including Birmingham, Cardiff, Cumberland, and Surrey. The total number of children immunized was 3,008. For residential institutions, in the metropolitan area and outer ring the immunizations were 1,952, and in the provinces 3,861. For fever hospital staffs, in both London and the provinces, the figure was 1,235, and for patients 221. In Scotland community immunization was carried out in Aberdeen burgh and county, Dundee, St. Andrews, and Edinburgh up to a total of 16,324 persons. Aberdeen burgh enjoys the distinction of being the scene of concurrent immunization by means of a combined prophylactic against both diphtheria and scarlet fever. For residential institutions the Scottish figure was 75, for fever staffs 486, and for patients 875. The total immunizations for Great Britain were, on a community basis, 19,332, and for all purposes, including community immunizations, 26,085.

It appears from the figures that community immunizations in Scotland were five times as numerous as in England and Wales together, and over forty times as numerous in proportion to population. The city of Edinburgh and Aberdeen burgh and county were the main contributors to this eminence.

In the United States immunization has been practised on an impressive scale. In New York City, for example, 400,000 children have been immunized since 1918, and the diphtheria death rate is reported to have fallen from 22.7 to 7.9 per 100,000. Chicago has immunized 179,453. Boston 57,699, and Rochester, Syracuse, and Utica in New York State have dealt with smaller numbers. The work is in progress also on the continent of Europe, in India and the Australian Commonwealth, and in Uruguay.

The report presents a comprehensive survey of the methods and results of immunization against diphtheria. It collates facts and figures derived from a variety of sources regarding enterprises undertaken or in prospect in this and other lands, and shows that in the matter of community immunization England does not occupy the same dominant position as in some other departments of hygiene.

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the Committee thirty-four cases were considered and £571 10s. voted to thirty applicants. The following is a summary of the new cases relieved.

Daughter, aged 62, of M.R.C.S. who died in 1876. Her only income is derived from a pension of £50, as her sister, with whom she was living, died recently and her pension died with her. At present applicant is living with an invalid niece. Voted £55, payable in monthly instalments.

Widow, aged 64, of M.R.C.S. who died in 1892. She has been advised to give up, owing to ill health and age, her nursing, with which she supported herself. Daughter, aged 25, is married, with two children, and is unable to assist the applicant; £75 was received from nursing in the past twelve months. Voted £36 in twelve monthly instalments.

Wife, aged 41, of M.B. who was helped by the Fund in February and August last year, as he is trying to build up a practice in a small way. The applicant is working in a small post on commission and has not made sufficient to cover expenses. Voted £12 towards some debts which had been incurred.

Widow, aged 69, of M.R.C.S. who died last year. She has two sons who are married, and is staying at present with the elder, but neither son is in a position to give financial assistance. Voted £35, payable in twelve monthly instalments.

Daughter, aged 60, of M.R.C.S. who died in 1913. She lives in Paris and has supported herself by teaching and making translations. Owing to illness has not been able to meet expenses. Voted £26.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos Street, Cavendish Square, London, W.1.

MEDICAL EDUCATION AT UNIVERSITY COLLEGE, LONDON.

ADDRESS BY SIR JOHN ROSE BRADFORD.

ONE of the centenary addresses at University College, London, was delivered, on May 13th, by Sir JOHN ROSE BRADFORD, K.C.M.G., M.D., President of the Royal College of Physicians of London, who took for his subject the history of medical education at the College.

Sir GEORGE THANE, who presided, said that one hundred years ago this country had no organized or authorized system of medical education; there was no Medical Act, Council, or *Register*. During the 16th, 17th, and 18th centuries in most countries of Western Europe, notably France, Italy, Germany, Switzerland, and Holland, medical education was provided and fostered in the universities in the same way, though not to the same extent, as the sister faculties of theology and law; in this country alone was practically nothing done. The great English physicians, Linacre, Harvey, Sydenham, and others, generally went abroad for their education and degrees. In Scotland and Ireland medical schools or faculties were set up in the universities and flourished more or less vigorously—Edinburgh being the most prominent—but in England no such action was taken by the old universities until the establishment of a university in London had already produced great results in developing medical education. Medical education was at that time controlled only by the regulations of medical corporations —the College of Surgeons and the Apothecaries' Hall—for the College of Physicians took no account of the great bulk of medical practitioners. These regulations imposed a certain number of years of study, mostly spent in apprenticeship, certain courses of lectures, and hospital practice. No curriculum was devised, and the lectures and hospital practice were attended in an indiscriminate, almost haphazard way. In a calendar of medical schools in London in 1828 Sir George Thane had found, besides the new University College, four hospitals with medical schools, three hospitals without medical schools, and seventeen schools teaching various subjects, anatomy generally the chief, and bearing such names as "The Theatre of Anatomy." There were also seven teachers who announced individual courses on various subjects, as well as half a dozen dispensaries, where it was a common thing at that time for instruction to be given. Such were the conditions when University College was founded.

Sir JOHN ROSE BRADFORD began with a reference to the late Professor Starling, who had delivered the first of the series of centenary orations. Starling, he said, was not a student of the College; he came there after a distinguished career in another great school, but he was as loyal and distinguished a servant of the College as any of the great men who had made its reputation.

The orator said that the distinction between the science and the art of medicine was not meaningless nor fanciful. The practitioner of medicine who did not regulate his art by his science often escaped criticism by reason of the common supposition that medicine was only an art and not a science, and that there was something mysterious about disease that left an opportunity for the action of chance. In other words, it was not realized that failure or uncertainty was due to want of knowledge or possibly to its misapplication. Whereas the art of medicine was very ancient, the science was of comparatively recent origin. Hippocrates was a great exponent of the art, but the science might be said to date from Harvey, a matter of some three hundred years; the application of the science to the art was of still more recent date, and it was here that University College had played a distinguished part. It was not a question so much of any particular discovery having been made within those walls, although there had been many discoveries, some of them great; but rather that there had been explored and encouraged there the broader relation of the science of medicine to other sciences and to the art of medicine, and, most important of all, the development of scientific methods and of the scientific type of mind in pursuit of the art of medicine. It might be said that in the science of medicine the disease was the focus of attention, and in the pursuit of the art of medicine that the patient was the first consideration. Yet little or no success was likely to be achieved if the art was pursued by unscientific methods or in an attitude of mind which ignored the law that like causes produced like results, and that the numerous seeming contradictions were not really exceptions, but were due to the conditions being not really the same, although appearing to be so. The great medical clinicians of the past were men who observed by the scientific method; hence the value of their results, which left their successors wondering at their skill despite the limitations of their knowledge. It was scarcely an exaggeration to say that the teaching of medicine in England had not advanced very much beyond this stage at the time of the foundation of the College.

The student of one hundred years ago had no opportunity of widening his outlook on life or of coming into contact with other branches of learning. It was true that the ancient seats of learning had small numbers of men who, having studied in the humanities, subsequently turned to medicine, but those universities did not afford facilities for the development of medical study; the later developments in the older universities in this direction were subsequent to the founding of University College, and not unconnected with what took place there. In 1828 medical education was practically limited to the provision of the instruction required by the licensing bodies, and this was not of a very extensive character. The London hospitals which had schools attached to them at this period were St. Bartholomew's, St. Thomas's, Guy's, and the London; they included on their staffs not only physicians and surgeons distinguished for their knowledge, but men who were capable exponents of some of the sciences ancillary to medicine. But the position was unsatisfactory—not only inadequate and imperfect, but lacking organization and systematization; the educational problem was considered from too narrow a point of view.

The founders of University College regarded medicine not only as a practical art of great importance, but also as a branch of learning which should take its place with other study in any university that deemed itself worthy of the name. There was one other university in Great Britain where these views prevailed; the debt of University College, London, to the University of Edinburgh was very great, and Edinburgh derived its inspiration largely from the University of Leyden. University College Hospital, like the Royal Infirmary, Edinburgh, was founded thanks to the young Faculty of Medicine. But in 1828, when the teaching began in University College, there was no hospital attached. A dispensary was opened, and certain arrangements were made with the Middlesex Hospital, but at this period regular systematic clinical teaching was *not* in vogue at any London hospital, the students doing no more than "walk" the hospital. The founders instituted two clinical chairs, one in medicine and the other in surgery, and as soon as University College Hospital was opened two clinical professors were appointed with the special object of training students in the observation and study of disease. The greatest thing the founders did was to place the teaching of each subject in the medical curriculum in charge of an expert in that branch, and this ensured that they should be viewed from a broad and not from a utilitarian point of view.

Among other developments he referred to the institution of practical classes in chemistry and in histology. University College did not follow the requirements of the licensing bodies and institute practical classes when these were made compulsory, but it had already established the practical classes to render the teaching more efficient and to ensure that the student's knowledge was obtained first-hand; the examining bodies followed suit. Another far-reaching development was the foundation of a chair of pathological anatomy in 1828; not until 1872, he thought, was this subject compulsory in the medical curriculum. At University College in season and out of season the teaching of medicine had been correlated with the teaching of morbid anatomy. A hundred years ago the student was largely the appanage of some individual member of a hospital staff whose paying pupil he had to become to obtain the advantage of following the practice in the wards. All

College, and said Sir John Rose Bradford in conclusion, was no light task, but so long as the teachers were inspired by the same ideals which spurred on the founders there was every reason to hope that, with the enormously improved equipment of the present, the successes of the future might be even greater than those of the past.

Sir GEORGE THANE, in expressing the thanks of the distinguished gathering, mentioned that it was forty-eight years since he himself spoke on the development of the medical school, and he regarded it as astonishing that he should be there on that occasion to add a postscript. He had declared as far back as the seventies that "the reputation of our College was made first by its teachers. It must now and in the future be maintained by its pupils. When the time arrives for the celebration of its centenary may it be said of us—and we need wish for no higher praise —that we proved ourselves worthy of our distinguished men who had served the College practically through the last half century—Thomas Barlow and Rickman John Godlee; to these he would add a third name, equally typical, but the name of a man still in the fullness of his service, that of John Rose Bradford.

Sir JOHN ROSE BRADFORD, replying, remarked on the pleasure with which they saw Sir George Thane once more in their midst, and said that whatever success he had himself attained it was due to the College and its teachers; among the teachers there was not one to whom he was more indebted than to Sir George Thane.

Nova et Vetera.

EARLY BOOKS ON SYPHILIS.

E ten tractates printed in the most recent volume we e received of Monumenta Medica1 all deal with syphilis, are believed to be not only the earliest printed matter the subject, but also the first examples of separate ted treatises on a single disease. They are reproduced csimile—black-letter type and illustrations. The introion by Professor Sudhoff has been translated and anged by Dr. Charles Singer, who has given a recension glish which has been revised by the author.

was printing which made possible the diffusion of dge of an ancient evil, and its recognition as a t venereal disease. Further, the common use of established the existence of the disease in Italy, France, and Germany. However great the imperof the tracts, the aim of their writers was to make contributions, not to repeat ancient texts and ions; experiences gained in practice were published novel in the disease they described, only a special he lifetime of the authors, who, it is clear, saw f pestilence which had recently undergone a great both in the number of cases and in their severity. nations of this increase were, however, in accord- traditional views—theological, astrological, and Whatever the popular opinion, medical tradition ed to the idea of contagion; though it was that the disease attacked the privy members, it nsidered venereal. Mercurial inunctions had stablished remedy, but irrelevant considerations importance.

ing is a brief summary of the contents of the

CHELLIG: *In pustulas malas. Consilium.* Heidelberg, ig, who was body physician to Philip, Elector panied him in 1495 to the Diet at Worms, which ct against blasphemy; among the pestilences it as sent in punishment of the vain use of me was included the pest termed in German

edica. Under the general editorship of Henry E. *The Earliest Printed Literature on Syphilis, being the years 1495-1498.* In Complete Facsimile, with an ther Accessory Material by Karl Sudhoff; adapted by rence; R. Lier and Co.; London: D. Stanton. 1925. 352; illustrated. 42 6s.; a special discount of 15 per by Messrs. D. Stanton.)

bösen Blattern, in Latin "Malum Francicum." Its recent diffusion seemed a new scourge of God; hence the Elector ordered Schellig to draw up a regimen to protect against the prevalent disease, but Schellig exhibits very slight acquaintance with the malady, and his prophylaxis was merely that current against pestilence in general, for which in the Middle Ages mercury was one of the drugs employed.

2 and 3. JOSEPH GRÜNPECK: *Tractatus de pestilentiali Scorra sive mala de Franzos.* Augsburg, 1496. Joseph Grünpeck of Burckhausen, a layman in physic, issued his tractate as a commentary upon Sebastian Brandt's verses on the *Mala de Franzos*, which had as a frontispiece a woodcut depicting the Virgin and Child; from the Child's hands streamed out barbed shafts that struck mankind, but changed the avenging arrows into healing rays. He gave an astrological explanation of the disease, a sinister conjunction of Saturn and Jupiter, in the sign of the Scorpion, the sign of the zodiac which dominated the genital sphere. Grünpeck, in a second tract, at the age of 30, noted that he had himself contracted the disease. In discussing treatment he mentioned mercurial inunction.

4. NICOLÒ LEONICENO of Vicenza: *Libellus de Epidemia, quam vulgo morbum Gallicum vocant.* Venice, 1497. After a long preliminary digression Leoniceno in the later pages of his pamphlet dealt with the morbus Gallicus, which he held not to be a novel disease. The Hippocratic Aphorism (III, 21) had mentioned together ulcerations of the mouth and mortification of the privy members as among diseases occurring in summer. He opposed the indiscriminate resort to mercury, because its use repressed the eruption, which, according to the prevailing pathology, indicated the elimination of the materies morbi. Moreover, he said, mercurial inunctions did not benefit every case.

5. CASPARE TORRELLA of Valencia: *Tractatus cum Consiliis contra pudendagram seu morbum Gallicum.* Rome, 1497. Torrella, a Spaniard, became physician to Pope Alexander VI, and although his clientèle was restricted to the family of Borgia and the papal court, nevertheless, in the two months September and October, 1497, he claimed to have treated successfully seventeen cases, the Pope's son, Cesare Borgia, among them. He distinguished five types of the disease. At first he attributed it to the *flagellum Dei*, but subsequently believed it had a French origin. It would seem that as early as the fourteenth century in Southern France a distinction began to be established between syphilis, leprosy, eczema, and other chronic diseases of the skin. This may explain the origin of the name "Mal. Franzoso"; it was treated successfully by mercury.

6. JOHANNES WIDMANN: *De pustulis et morbo qui vulgo mal de franzos appelatur.* Rome, 1497. Widmann was a physician at Tübingen, where he was an inspector of lepers. His experience caused men to distinguish the morbus Gallicus from leprosy; in both alike he deemed the breath a source of contagion. Among the factors producing the disease he refused to admit either the Divine anger or the influence of the stars; his theory of its nature was based upon the doctrine of the four humours. For prevention he recommended the same measures which had long been in vogue for the prevention of leprosy. He employed two forms of mercurial ointment.

7. CORRADINO GILINO: *De morbo quem Gallicum nuncupant.* Ferrara, 1497. Gilino followed Galen and Avicenna; for treatment he used metallic mercury ointments to which some sublimate was added. Later the sublimate was restricted to washes and fomentations, but this practice was attacked by Paracelsus, who had learnt about the disease for the first time in 1496. He identified it with the *ignis persicus* of the ancients, and applied the actual cautery to the scalp over the coronal suture in order to stimulate the downflow of *pituita* from the under aspect of the brain into the nasopharynx, and so to eliminate the materies morbi.

8. BARTHOLOMAEUS STEBER of Vienna: *A Malafranzos, morbo Gallorum praeservatio ac cura.* Vienna, 1498. Steber gave an illustration of two patients, a woman with the physician at her bedside viewing her urine, and a man to whom a second practitioner is applying ointment on a spatula. Steber sought to differentiate syphilis by means of the rash, the *bosen Blattern*; other signs and symptoms he almost ignored. As to causation he discussed the influences of the humours and of the stars; for prophylaxis he repeated the general prescriptions given by Galen. Treatment by mercury he mentioned incidentally as though he had no great faith in it.

9. NATALE MONTESAURO of Verona: *De dispositionibus quas vulgares mal franzoso appellant.* 1498. Montesauro had a much better acquaintance with the disease, including the polymorphic character of the eruption; he was the first to mention the osteocopic pains, but he was sceptical as to the value of mercury, and knew of cases without primary affection of the genitalia.

10. ANTONIO SCANAROLI of Modena: *Disputatio de morbo Gallico.* Bologna, 1498. Scanaroli supported his teacher Leoniceno in opposition to Montesauro. He held that the disease was not passed by sexual intercourse, but arose in the sexual organs *de novo*; his evidence was its occurrence in virgins and in aged men past sexual life.

British Medical Journal.

SATURDAY, MAY 21ST, 1927.

BIOLOGY AND MEDICINE.

THE current issue of the JOURNAL includes a contribution by Dr. J. S. Haldane on the relationship between biology and medicine, which is of both practical and theoretical interest to the medical practitioner. "Health," he says, in his introduction, "is a normal condition which tends to be maintained apart from any conscious effort to maintain it," and a more concise and adequate definition, and one more rich in meaning, it would be difficult to formulate. The use of the term "maintain" is significant; it conveys the suggestion that health is the expression of an active process taking place within the organism, of a fundamental conative tendency, and thus gives it that dynamic quality which is the essence of Dr. Haldane's conception of unconscious life. He reiterates in this article the view which has been more fully developed in his other writings, that a mechanistic hypothesis is inadequate to account for the distinctive phenomena of life. He points out that in the case of life the structure, including its mass and composition, is actively maintained in a particular manner which we call "normal"; that the activity of the structure is of such a nature that the normal structure is maintained and developed; and that normal structure and normal activity are thus inseparable. Briefly, the living organism has to *do* in order to *be*. Furthermore, the organism must be continuously active if it is to maintain its existence, and thus the definition of sleep as "the resting time of consciousness" more or less accurately describes what happens in that state, for the organism itself can never sleep.

Another distinctive feature of the living organism, emphasized in the address, is that it functions as a whole. Modern medicine increasingly reveals the inadequacy of the idea of independent functions. The activities of organisms are no more sharply divisible into "functions" than are mental activities into "faculties." The body cannot be regarded as a series of isolated systems. From the behaviour of an isolated perfused kidney or lung, as Dr. Haldane observes, we gain little knowledge of the amazing delicacy with which the kidneys and lungs in an intact man or animal regulate the composition of the internal functions. Attention is, in fact, directed away from this regulation, whereas when the living body is intact experiments which are easily carried out in man reveal the regulation in the most striking manner. Thus no system has an independent function, and no organ or function is directly dependent upon any other organ or function, but, on the contrary, all reaction results from the collaboration of all organs. Furthermore, as is pointed out, the relation of the living organism to its environment is no less peculiar and specific than the relationship of the internal parts and activities of the organism itself. Between organism and environment a constant active exchange is going on. But this exchange is always determined in relation to the rest of the living activity of the organism. Whether material is to be taken up or given off, whether and to what extent the organism is to respond to any stimulus, all this is determined in relation to the life of the organism as a whole. The living body and its physiological environment form an organic whole, the parts of which cannot be fully understood in separation from one another. The activity of the living organism is necessarily affected by every physical agency which impinges upon it—atmospheric conditions, pressure, temperature, moisture, electrical states and disturbances, all these have an inevitable influence upon all the reactions and functions of the organism.

Thus since the living organism functions as a whole, Dr. Haldane insists that we should endeavour to study its reactions in the intact organism. This principle has an important bearing upon the problems of practical medicine, and that this is so becomes particularly evident when we endeavour to solve the obscure problems of psychiatry. We here refer to this branch of medicine because Dr. Haldane has recently expressed a view, which has been the subject of much discussion, that the real causes of illness in nervous disorders are physiological, and that these causes, when discovered, will give us an adequate theory of the so-called functional nervous disorders.[1] He suggests that these disorders only appear of a different nature from the ordinarily recognized organic nervous disorders because an inadequate and too mechanical view of physiology, especially that of the nervous system, is held; and that we should make our physiological explanations more general in terms of the entire organism, passing beyond the abstractions of the reflex arc. The validity of this view would seem to be strikingly exemplified in an investigation on the psycho-galvanic reaction in the subjects of hysteria by Dr. F. L. Golla.[2] This reaction is a reliable and exquisitely delicate method of demonstrating the existence of the physiological disturbances which are associated with affective or emotional states. In normal persons it is invariably elicited in response to nocuous stimuli, either physical or psychical. In hysterical subjects, however, Dr. Golla found that the galvanic response to similar stimuli was absent or sub-normal. Such patients would start or tremble and exhibit the external manifestations of fear at a loud noise or painful stimulus when a normal man would hardly budge, yet their galvanic response revealed an undisturbed state of the organism. Even when the hysteric was engaged in the exhibition of a severe crisis his organism remained in a state of perfect tranquillity. Thus a study of the physiological behaviour in these patients revealed the existence of an organic disability which does much to explain the clinical manifestations of the hysterical syndrome. It is therefore evident, as Dr. Haldane suggests, that if we are to gain an adequate knowledge of the cause of psychoneurotic illnesses, we must not confine our investigations to the activities of the patient himself, but we must also extend them to those of his organism.

Dr. Haldane describes life, with its essential co-ordination, as a constant, and under normal conditions successful, struggle with the essential chaos of what we interpret as a chemical and physical world, both within the organism and in the environment. That this is descriptive of the facts becomes evident when we consider the nature of the events which take place when life has departed from the organism. It ceases to maintain the erect posture and becomes subject to the law of gravity; it disintegrates into the inorganic, and how quickly this happens depends on purely fortuitous circumstances—the state of the

[1] Psychology and Biology. *Psychology and the Sciences.* London, 1925.
[2] *Proc. Roy. Soc. Med.*, vol. xvi, No. 4, February, 1923.

organism at the time of death, the temperature or humidity of the air, and the nature of the soil in which it is placed. The organism now exhibits a state of inertia instead of one of activity; and organic order is replaced by physical chaos. It is evident that the living organism must necessarily be engaged in a ceaseless struggle in order to maintain its existence in the face of conditions which, apart from the life within it, would reduce it to dust. A purely biological view of life thus tends to provoke a somewhat pessimistic attitude, because physics and chemistry must inevitably assume control of events sooner or later. Dr. Haldane has shown elsewhere,[5] however, that when we examine conscious activity or personality we find ourselves in the presence of an order of observations differing greatly from those with which biology deals, and it is only by so doing that we gain an adequate appreciation of the symptoms and meaning of life as a whole.

THE COMMUNITY CONTROL OF DIPHTHERIA.

It was known long ago to the fathers of medicine that the appearance of membrane on the throat was ominous. "A web on the tonsil is not good" was the view expressed by Hippocrates, and Aretaeus refers to the exudate followed by dyspnoea from which the chief sufferers were children. The Arabs are mainly silent on the subject, but in the eleventh century, as Cedrenus narrates, a suffocative disease so raged in themes of the Empire that the living could not bury the dead. Baronius about the same period comments with pity on a similar outbreak in Rome. In the great Spanish epidemic, which culminated in 1613, called *año de los garrotillos*, Villa Real, who saw thousands of cases, observed with acuteness the signs of the malady, but had no sure way to relieve it. And modern physicians, however distinguished, up to near the close of last century, could do little to mitigate and nothing to stay the course of the diphtherial infection till, in 1890, the diphtheria antitoxin was introduced and medicine thus dowered with a specific remedy against the dreaded disease. The beneficent results of the new cure were not long in becoming manifest. The case mortality of diphtheria, which, prior to 1894, when antitoxin came into effective service, had stood at 30 per cent., fell in a few years to 10, and the hope was not unreasonably cherished by many that with the extended use of so apt a reagent the fall might continue unbroken and diphtheria in a few more years be relegated to the group of mild and little-regarded diseases which seldom terminate fatally.

Experience, however, has not wholly confirmed these sanguine anticipations. The case mortality, it is true, has continued to fall, but its rate of decline has slackened. In London, for example, over three seven-year periods between 1904 and 1924, as quoted in the report by Dr. J. Graham Forbes, analysed elsewhere in this issue (p. 925), the retarded rate of decline is represented by the unsubstantial difference between 8.88 per cent. for the first of the periods and 6.98 per cent. for the last. That an early fall should be followed by retardation was perhaps inevitable in the circumstances. In the earlier stages enlightened parents who were prompt to seek medical aid for their children, and well informed practitioners who, suspecting diphtheria, either administered antitoxin on suspicion or secured the immediate removal of the patient to hospital in order that antitoxin might be given, combined to produce the best condition for the remedial efficacy of antitoxin—that is to say, its application early in the course of illness. The competent medical staffs of isolation hospitals also, giving antitoxin in heroic doses and by the intravenous method where necessary, were able to save patients in an advanced and even desperate state whose lives would otherwise have been lost. Thus the knowledge of the new remedy spread most quickly among those who were best fitted to turn it to account, and the spectacular fall in the case mortality of diphtheria during the early years of antitoxin treatment is referred to its probable cause. There remains, however, an unhappy residue of shiftless or indifferent parents who do not notice when their children are ailing, and of dilatory practitioners who, before giving antitoxin, will await the fiat of a bacteriologist. These fail at the critical moment. Death still may strike through their feeble defence at neglected or mismanaged cases, and their lagging methods are in great measure responsible for the retarded rate of the decline of case mortality so notable at this juncture. Even in the possible presence of a recent increase in the actual virulence of diphtheria this statement appears to hold good.

Except for the discredit which naturally attaches to the occurrence of any death from diphtheria in a well governed modern city with a public health service, motor ambulance transport, and good isolation hospitals, it may be urged that a refractory remnant of case mortality is, after all, no great matter, that things are undoubtedly better than they were, and that, given time, the sluggards in the field may be brought into line at last. Time, however, cannot be given, for time fails. Both the attack rate and the death rate from diphtheria, as distinguished from the fall in its case mortality, have begun to display an upward tendency. The movement, as shown in Dr. Forbes's report, is most manifest among the greater cities, in a number of which either the attack rate or the death rate or both have risen in the last few years. Their relative weight varies as between city and city, but over the period of fifteen years ended 1925 London, Edinburgh, Portsmouth, and Bristol head the lists for both rates, although in different order. Diphtheria in Britain appears to be entering on a new and disquieting phase, and the cure of the sick by antitoxin treatment, under the limitations above described, may not suffice to control the mortality.

An appropriate instrument to avert the menace is fortunately ready to hand. The toxin-antitoxin prophylactic against diphtheria, first applied to children in New York City in 1914, has attained wide vogue in the United States, where the number immunized is now well over half a million. In Scotland, between 1921 and 1926, 16,324 children were immunized on a community basis, with or without a previous Schick test according to their age. For England and Wales the corresponding figure is 3,008. Of the Scottish people 1 in 175 has received active protection; of the English 1 in 4,560. In recent procedure the original toxin has been replaced by toxoid.

The community immunizations effected in this country are still too recent for harvest, but towns in the United States which have immunized their children, from New York and Chicago to Auburn and Utica, claim a definite fall in the diphtheria incidence. In British hospitals where the nurses have been

[5] *Mechanism, Life and Personality.* London, 1921.

treated their diphtheria attack rate has been reduced or abolished. The method must be regarded as fully accredited, and in the face of an apparent rising prevalence of diphtheria the time has come for its wide adoption in England on a community basis. Two hundred children can be immunized at the cost of one case of diphtheria. It is needless to enlarge on the relief of suffering and the escape from death. "A web on the tonsil" is no better now than it was in the days of Hippocrates.

THE JUBILEE OF THE PHYSIOLOGICAL SOCIETY.

THE Physiological Society, at the end of last week, celebrated its jubilee by a dinner in London and a meeting in Cambridge. The selection of places was appropriate, for it was the physiologists of these two seats of learning and some of their friends who brought the Society into existence a little over fifty years ago. At the dinner, which was attended by a large number of members and a few guests, Sir Edward Sharpey-Shafer, who was in the chair, in responding to the toast of the Society, which had been given by Dr. Walter Elliot, M.P., related the circumstances that induced the physiologists fifty years ago to band themselves together. They were feeble in number, their laboratories small and imperfectly equipped, and their science hardly recognized as an independent department; but they were strong in faith, and strong in the support of a few among the leaders of science of the day, who, though not themselves engaged in physiology, were wide-minded enough to foresee that the study of the mechanism of life was an essential element in the advance of science as a whole; also at this time physiology was being attacked on the ground that its methods of research involved cruelty to animals; a Royal Commission had sat, and its report, it was known, would lead to legislation. It was felt, therefore, to be very necessary that any bill which might be introduced should be carefully examined. In March, 1876, an informal meeting was held at the house of Dr. (afterwards Sir) John Burdon-Sanderson, in London, to consider the situation. It was attended by nineteen persons, and it was there and then decided to form a physiological society, which should be limited in number and should be a sort of dining club. Invitations were issued to forty persons, and four of them survive—Sir David Ferrier, Sir W. Thiselton-Dyer, Sir E. Ray Lankester, and Sir E. Sharpey-Schafer himself. The first dinner was held at the Criterion Restaurant in London, when Sir Michael Foster was in the chair, and among those present was Sir William Bowman, showing that even at that early stage the Society welcomed the support of the physiologist turned clinician. The restriction of the number of members was shortly relaxed, and was for a time fixed at sixty, but later on it was very much extended, and the Society now contains over 400 members. At the jubilee dinner Sir Charles Sherrington gave the toast of the Society, coupling it with the names of Sir Ernest Rutherford, who had come to honour this offshoot of the Royal Society over which he now presides, Professor Fano of Rome, Professor Gley of Paris, and Viscount Knutsford, who had not only devoted his energies to the maintenance and extension of the London Hospital and its school, but had helped experimental physiology through the Research Defence Society. Sir Charles Sherrington mentioned also the help that had been given by the British Medical Association through its JOURNAL and in other ways, by the *Lancet*, by *Nature*, and by the Royal Society of Medicine, whose president, Sir James Berry, was present. Sir Ernest Rutherford, in a short speech, dwelt on the relation of physiology to physics, giving several instances, in particular, Einthoven's string galvanometer, in which a physical apparatus had been developed by a physiologist for a highly specialized purpose, but had afterwards been adopted in physical laboratories as a delicate recording device. Professor Fano and Professor Gley also replied; Lord Knutsford, in the course of his remarks, appealed to all physiologists to join the Research Defence Society, and to help it by supplying it with accurate information and by speaking for it when necessary in vindication of the importance of experiments on animals to medicine. The toast of "The chairman" was given by Dr. Leonard Hill, who recalled that he had himself worked as Sharpey scholar under Professor Schafer, and went on to make complimentary references to the physiologists trained by Professor Schafer, who had gone out to many schools in Great Britain, in Ireland, in Canada, South Africa, New Zealand, and Australia. On the following day a very largely attended meeting of the Society was held in Cambridge. Among the papers read was one by Professor A. N. Richards of Philadelphia on the elimination of phenolsulphonephthalein by the kidney, another by Professor J. G. Dusser de Barenne of Utrecht, on respiratory exchange during static and phasic work, and another, which was followed with deepest interest, in which Sir E. Sharpey-Schafer related the results of certain experiments made on his own person to investigate the recovery of sensation after severance of cutaneous nerves in man. On Sunday afternoon Professor and Mrs. Barcroft gave an afternoon party in the hall and Fellows' garden of King's College. We understand that Sir E. Sharpey-Schafer has prepared a history of the Society, which will shortly be published in the *Journal of Physiology*.

THE UNIVERSITY OF LONDON SITE.

IN the north-west corner of the excellent plan in Dobie's *History* of the United Parishes of St. Giles-in-the-Fields and St. George, Bloomsbury, published in 1829, we find the words, "The London University." This referred to the ground on which University College now stands, and it is only a furlong from the site on which the headquarters of the University of London are to be built, so that the prophecy implied by this plan may almost be fulfilled. That part of Bloomsbury which lies to the north of the British Museum and Bloomsbury Square is so modern that tradition and local history have hardly had time to form. When Dobie's plan was made Torrington Square was new. "Torrington Square," he said, "is also on the Duke of Bedford's estate, and is lately in a state of completion. It contains seventy houses of moderate size, and is so pleasantly situate on an elevated healthy spot, as to have been filled with occupants, as fast as it progressed in building." Woburn Square was then "a new square now forming, to be called Rothsay Square." Until the beginning of the last century open fields lay between the British Museum and what was then and long after the "New Road," and now Euston Road. These "fields behind Montagu House" were long notorious for duels. Smollett in *Roderick Random* and Thackeray in *Catherine* took some of their characters there to engage in single combat. At a part of the fields situated near the north-eastern corner of Torrington Square were the famous forty footsteps. The story runs that in the year 1685 two brothers quarrelled, fought, and both died at this spot. In the desperate struggle they made forty deep impressions of their feet in the soft ground, on which no grass or other thing would thereafter grow. Hence that field was called "The Field of the Forty Footsteps." For at least a century afterwards it was visited by curious persons, who generally came away well convinced of the truth of the story and of the genuine effects of the curse which had fallen on the scene of fratricide. The footsteps persisted until the ground was covered by buildings, but their exact situation is doubtful. J. T. Smith of the British

Museum, who died in 1833, in his *Book for a Rainy Day* wrote:

"The whole of the ground north from Capper's farm, at the back of the British Museum, so often mentioned as being frequented by duellists, was in irregular patches, many fields with turnstiles. The pipes of the New River Company were propped up in several parts to the height of six and eight feet, so that persons walked under them to gather watercresses, which grew in great abundance and perfection, or to visit the 'Brothers' Steps,' well known to the Londoners. Of these steps there are many traditionary stories; the one generally believed is, that two brothers were in love with a lady, who would not declare a preference for either, but coolly sat upon a bank to witness the termination of a duel, which proved fatal to both. The bank, it is said, on which she sat, and the footmarks of the brothers when pacing the ground, never produced grass again. The fact is that these steps were so often trodden that it was impossible for the grass to grow."

Smith's explanation was not generally accepted, and even the poet Southey supported the opinion of a writer in the *Gentleman's Magazine* in 1804 that "the Almighty has ordered it as a standing monument of his great displeasure of the horrid sin of duelling." In 1828 the then celebrated authoresses, Anna Maria and Jane Porter, made the story the theme of their novel *The Field of the Forty Footsteps*. A much older superstition connected with these fields is recorded by Aubrey in his *Miscellanies:*

"The last summer, on the day of St. John Baptist (1694), I accidentally was walking in the pasture behind Montague House; it was twelve o'clock. I saw there about two-and-twenty young women, most of them well habited, on their knees very busie, as if they had been weeding. I could not presently learn what the matter was; at last a young man told me that they were looking for a coal under the root of a plantain to put under their heads that night, and they should dream who would be their husbands. It was to be found that day and hour."

This was evidently a variant of one of the widespread superstitions of pre-Christian origin connected with Midsummer Day. Between what is now Torrington Square and Gower Street was the ground of the Royal Toxophilite Society, founded by Sir Ashton Lever in 1781, of which the Prince of Wales, afterwards George IV, was patron. Their earlier practice ground had been the lawn at the back of Leicester House. There is some medical interest in the story of the origin of Sir Ashton Lever's interest in archery. A friend, a Mr. Waring, who had acquired an affection of the chest which the doctors could not relieve, resolved to try the effect of archery. He was cured, and attributed his cure to the bow. This led to others taking up the exercise and to the foundation of the society. A number of well-to-do people were members, and dinners and suppers seem to have played an important part in their proceedings. The society removed in 1821 to a piece of ground of four acres in Bayswater, nearly opposite the present Victoria Gate, and later to the Regent's Park, whence it has only recently departed. Torrington Square is distinguished only by the antiquaries who lived there. The Rev. Joseph Hunter, a presbyterian divine, died at No. 30. He was an indefatigable archaeologist who began his inquiries into ecclesiastical monuments and such-like while a boy at school near Sheffield, and continued them throughout a long life, during which he produced a vast number of publications on various subjects; he died in 1861. No. 55 was the last English residence of Sir Nicholas Harris Nicolas, the editor of Nelson's dispatches and author of a *Chronology of History*. He had served in the Royal Navy for some years during the Napoleonic wars and carried into civil life some of the breeziness said to characterize that service. He did much to reform the Society of Antiquaries and the methods of the Keepers of the Records, but that malady of the purse, once described by Theodore Hook as "a tightness of the chest," drove him to seek refuge at Boulogne, where he died in 1848. Keppel Street, Keppel Mews, and most of Montague Place have been swept away in the improvements at the north of the Mu formation of the grand avenue of approach in particular to the doors which are never No. 1, in which Constable, the painter, lived gone with the rest of Keppel Street. The versity is now to have a local habitation worthy of it. If the traditions of the site great nor many, the future will doubtless mal deficiency in past history of this part of Bloo

THE LISTER INSTITUTE.

THE governing body of the Lister Institute Medicine presented its thirty-third annual members at the general meeting held on Ma report furnishes abundant evidence of grea all branches of research, but it is only po place to refer to a few of the more impo recorded in the several departments. Dr. A studied the properties of the two main kin in the coli group of bacteria—namely, the h the heat-stable types. Of the four variants *typhosis* A studied, two, which grew as "smo and afforded heat-stable antigen, have been the more virulent and to make good prote for guinea-pigs. The two "rough" variant this antigen, are only feebly virulent and m inefficient vaccine. The virulence and the vaccine are, therefore, both related to the heat-stable antigen. The results with *B. typ* were in the same direction but less distinct. tance of securing a "smooth" virulent cultu vaccine has not hitherto been realized. Dr has continued his studies on the phosphoric blood and the enzymes by which they are sy hydrolysed. The synthetic power of the enz demonstrated, using inorganic phosphate of glycerol; and the hydrolysis of phosphor been shown to increase rapidly with increasi Experiments in calcification were made by p stream of solution containing calcium, inorgani and a small quantity of phosphoric ester rickety bone. A deposition of calcium ph place, which is roughly proportional to the of the phosphoric ester in the solution; in of the ester, calcification does not occu Korenchevsky has investigated the influenc ectomy on the heat-regulating mechanism. ectomy, cooling causes a much more pronou warming a much smaller increase of temp in normal animals. The normal adjustm mechanism may be restored by thyroid fe the feeding is excessive the animal is severely when exposed to temperatures previously we and the body temperature may rise to 43 concluded that the thyroid plays an importan regulation of the body temperature. In th of protozoology Dr. Muriel Robertson has in the study of the para-basal body of fla Dr. H. M. Woodcock on encephalitis in rabb cystic disease of the mouse. In the depart study and preparation of antitoxic serums, F. and Hedley Wright investigated an interes pneumococcal endocarditis in the horse. Th being actively immunized against a Type pneumococcus which was highly virulent fo and its serum was strongly protective for this virulent strain. It developed fatal endocarditis and septicaemia after a series o injections with living cultures. The strain re the blood proved to be non-virulent for regarded as a variant of the original virulent

factors involved in the genesis of this variety of endocarditis are not wholly understood, and their elucidation is likely to throw a good deal of light on the pathogeny of acute and chronic endocarditis in man. Dr. Maitland and Mrs. Burbury have continued to devote themselves to the work for the Foot and Mouth Research Committee of the Ministry of Agriculture; this has been carried on under the supervision of Dr. Arkwright on the same conditions as in 1925-26. Results of considerable importance have been obtained in the following directions: (1) it has been found possible to give a considerable degree of protection to guinea-pigs by a vaccine consisting of foot-and-mouth virus killed by formalin; (2) the influence of a variety of conditions upon the survival of the virus has been studied; (3) the virus has been found to remain active for many days in the bodies of dead guinea-pigs; (4) the rate of destruction by heating to different temperatures has been ascertained; (5) and the behaviour of the infection in rats and rabbits has been further studied. The disease was not found to pass naturally by contact, so that the significance of these animals as possible carriers seems to be small. Acting on a request from the Empire Marketing Board for advice as to the best means of preserving fruits, vegetables, and dairy products in order to retain their vitamins, the Institute has agreed to undertake an investigation on the subject. This will occupy five years, and it is to be carried out in the biochemical department under the supervision of Professor Harden. The National Collection of Type Cultures has been maintained, and the number of cultures distributed to applicants during the year remained at the previous high level of something over 4,000.

SUMMER DRINKS.

In warm weather, when we have it in this country, many people resort to refreshing drinks flavoured with orange, lemon, and lime juice, and there are some houses where it is the practice to serve all the year round, last thing at night, a lemon drink, usually made with barley water. Moreover, there is at least one famous club in London where lemon barley water is always on tap. But all these are made at home. We have been asked by Dr. Harries of Aberystwyth for an analysis of such drinks, in order that medical men who prescribe them may know what they are recommending. All these fruits yield juices of one generic character, containing acids, sugars, and volatile oil or flavouring principle, together with mucilaginous and nitrogenous substances. The chief acid is citric, but malic acid may be present in smaller proportions. The sugars are cane sugar and invert sugar. The mucilaginous and nitrogenous substances have no individual qualities of a distinctive nature; they are related to the groups of which pectine and asparagine are types. The proportions of acid and sugar may vary in different specimens of the fruits, particularly in the orange; analytical tables do not, therefore, give a reliable indication of the composition of an untried fruit. For practical needs the fruits used may be classed as sour or sweet. The lemon, with about 8 per cent. of citric acid, 1.5 per cent. of invert sugar, and 0.5 per cent. of cane sugar, represents the extreme of the sour kind, while the orange, with about 1.5 per cent. of citric acid, 4 per cent. of invert sugar, and 5 per cent. of cane sugar, serves as a good example of the sweeter. Intermediate proportions of these constituents produce corresponding degrees of sweetness or sourness, but in their domestic preparation cane sugar is often added. Fruit juices keep badly, for they have a tendency to grow prolific crops of moulds, and with the exception of lime juice are therefore not usually prepared for storage. They are usually made fresh in the domestic kitchen. Lemon drink can be prepared by paring two lemons into a jug, adding the juice (and a little sugar if desired), and pouring on a pint of boiling water. Most of the refreshing drinks sold in shops and booths are not described by the vendors as simple fruit juices. Lime juice is, however, prepared for sale, and for it there is a considerable popular demand. Formerly it was usually preserved by the addition of salicylic acid, but the only preservatives now permitted are benzoic acid (600 parts per million) or sulphur dioxide (350 parts per million). By a regulation of the Board of Trade, lime juice must be carried for the crews of vessels making long voyages, to prevent scurvy. Valuable as these fruit juices are for the vitamins they contain, it hardly follows that they should be used by invalids on every occasion when a refreshing drink is desired; the orange, for instance, is believed to contain a principle, not hitherto isolated, which, it is said, tends to cause "biliousness."

DEATHS UNDER ANAESTHETICS.

DR. F. J. WALDO, coroner for the City of London and Southwark, has issued a supplement to his report for the year 1926, in which, among other matters, he refers especially to deaths under anaesthetics. The number of deaths due to, or accelerated by, the administration of anaesthetics was sixteen, an increase on previous years; seven of these were attributed to chloroform or a mixture containing chloroform, seven to ether, and two to nitrous oxide gas and oxygen. As recorded in the annual reports of the Registrar-General, the number of deaths from anaesthetics had doubled between 1911 and 1925. Dr. Waldo remarks on the increase in recent years of deaths accelerated by ether as compared with those from chloroform, and on the fact that since 1911 the number of deaths from ether had exceeded that from chloroform given alone. During the present year verdicts had been returned in seven cases, and in six expert opinion was unanimous that death was accelerated by ether. In Dr. Waldo's opinion the facts disclosed call for some action with a view to diminishing the risks from the administration of anaesthetics, and he makes the following suggestions: (1) That an analyst's certificate of purity should accompany all anaesthetic ether, and that the ether should be delivered to hospitals packed in small quantities in light-proof packings, in order to prevent the spontaneous formation of deleterious substances; (2) that the recommendation of the Home Office Departmental Committee on Coroners and Anaesthetics (1910) should be put into force—namely, (*a*) that notification to the coroner should be made compulsory by surgeons, anaesthetists, and others having knowledge of any death under the influence of an anaesthetic, whether in private, or nursing home, or medical institution, and (*b*) that a small research committee of experts, nominated by the Home Secretary and paid by the Treasury, should be appointed to co-operate with coroners in respect of inquests held on those dying under the influence of anaesthetics, and to investigate all matters —with a view to prevention—connected with anaesthetics. The framers of the Coroners (Amendment) Act, 1926, now coming into force, did not adopt these recommendations. It is possible that clause (*a*) of suggestion (2) may have been considered too wide, since it would seem to insist on the notification of almost every death under operation throughout the country, whether due to the anaesthetic or not. Similarly with regard to clause (*b*), which may have seemed to foreshadow less the taking of evidence in particular cases than the initiation of prophylactic research. Probably at no period has the scientific study of anaesthetics and anaesthesia been pursued with such assiduity as at the present time; but the subject is in the experimental stage, and there is still great diversity of opinion on important points, as there necessarily must be until

general principles are established. It may have been considered that the men at the front, if one may use the simile—the anaesthetists themselves in conjunction with the surgeons—are more competent to deal with the matter than a court. Dr. Waldo, however, has done a service in calling attention to the statistics.

MEDICAL MISSIONARY WORK IN UGANDA.

IN April, 1876, the Church Missionary Society sent its first party of missionaries to Uganda, and on May 14th, 1897, its first hospital opened its doors at Mengo, the native capital of Buganda, which had come under British influence seven years previously. The passage of fifty years of medical missionary work in an area extending over nearly 100,000 square miles has been celebrated by the publication of a commemorative volume. The hospital had twelve beds in 1897 and 210 in 1927, and with it are associated medical and maternity training schools and country maternity and child welfare centres. Careful clinical records were kept from the start, and the large number of cases of spear and bullet wounds indicates one difficulty of those early days, when two native rebellions threatened to extinguish the British influence. Dr. A. R. Cook, who opened the hospital, and is still directing it, was joined two years later by his brother, Dr. J. H. Cook, and they worked together in Uganda until 1920, when the latter returned to England. From the first periodical medical visits were paid to the surrounding country, and in this way the foundations were prepared for the establishment of daughter hospitals at Toro, 200 miles to the west, in 1903 and Ng'ora and Teso in the Eastern Province. Enlargement of the hospital at Mengo was soon found necessary and the new building was opened in 1900 by Sir Harry Johnston. Two years later it was struck by lightning and burnt down, but another hospital was quickly erected and still serves as the men's block. Various buildings were added gradually, including a new dispensary in 1905, constructed and stocked by Mr. H. S. Wellcome. The large block now used as the women's ward was opened in 1910 by Colonel Roosevelt, later President of the United States, and an *x*-ray apparatus was installed—the first in Central Africa. Two years afterwards a hospital for European patients was added, and in 1915 accommodation was provided for Indian and Goan patients. In the meantime branch dispensaries in country districts were opened and supervised. The war conditions of 1914-17 necessitated expansion of the institution to 530 beds at one time, since the Southern Uganda frontier bordered German East Africa, and the hospital at Mengo was the only one of any considerable size in the Protectorate. With the local close of the war in 1917 an active educational policy was adopted, which led to the foundation of medical and maternity training schools. In January, 1917, a medical training school was opened—the first in the Protectorate. There were seventeen entries, and three years later the first four students passed an examination for qualification. With the institution of the Government medical school at Makerere, near Mengo, the hospital school closed for a time, but was reopened in 1924. A maternity training school was founded in 1918 in temporary quarters, and the large Lady Coryndon maternity training school was opened in June, 1921; since then forty-two midwives have obtained the Government and C.M.B. certificates. In 1925 a large school at Nakifuma, in the centre of a population of about 45,000, was opened for the post-graduate training of the midwives before they were drafted to centres for independent work. Uganda was the first African dependency to initiate legislation for the control of midwifery, and its example has been followed in Kenya and the Belgian Congo. This necessarily brief account does but scant justice to an arresting record of the success which has followed patient and devot treatment and education. The Church Missiona is to be congratulated on having produced such memorial of pioneer work in what can no longe "darkest Africa."

IMPURITIES IN ETHYLENE.

SOME of the difficulties that may attend the in into clinical practice of a new drug are shown i report on ethylene by Sherman, Swindler, and The occurrence of carbon monoxide poisoning a to ethylene anaesthesia led the authors to make analysis of the brands of ethylene used for a in Pittsburg hospitals. This analysis had the sensational result of showing that several samp brand of ethylene contained significant amounts monoxide, and that one sample actually conta 1 to 2 per cent. of this gas, a concentration su produce death in from ten to fifteen minutes. T speak very highly of ethylene as an anaesthetic sider that there should be no special difficu commercial production in a high degree of purit while, however, they have adopted the prec checking the purity of each individual cylinder used for anaesthesia. For successful anaesthesi of a high degree of purity is essential. Apart obvious danger of such a highly toxic impurity monoxide, other impurities may increase the explosion, and even the presence of water may to trouble by its vapour causing the freezing of

POST-GRADUATE TEACHING IN EPIDEMIO

A SPEAKER at the recent meeting, noticed of the Section of Epidemiology and State of the Royal Society of Medicine commente fact that little provision is made for the te epidemiology to medical students. It is, of cour that the present curriculum, like the miller's a be made to carry an additional load, but th should be some provision for the post-graduates to acquaint themselves with modern methods in this field. As we announced recently, th School of Hygiene and Tropical Medicine has alr steps to meet the immediate needs of studen class in the field of bacteriology. We unders somewhat similar provision is to be made wi to epidemiology and methods of investigation bacteriological. It is proposed that Profess Greenwood, who, it will be remembered, was not long ago to the chair of epidemiology and vita in the new school, should, pending the complet school buildings, carry out some of the duties o in the statistical department of the National of Medical Research, Hampstead. As at presen Professor Greenwood will receive small groups graduates to work in his department on various if possible those of particular interest to thems so acquire practical knowledge of the usual epidemiological and statistical investigation. be little doubt that for post-graduates the plan informal meetings at which, under the chairman teacher, workers discuss the problems upon v are engaged, is a better method of instruc didactic lectures, and this experiment deserves "Refresher" courses for officers in the Pub Service may also be held. Inquiries should be to the Director of the London School of Hy Tropical Medicine, 37, Torrington Square, W.C

England and Wales.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE annual meeting of King Edward's Hospital Fund for London to receive the accounts and report for 1926 was held at St. James's Palace, on May 13th, when the President, H.R.H. the Prince of Wales, was in the chair. Lord Revelstoke, the treasurer, reported that the net receipts had exceeded the original estimate of the grants for the year by nearly £5,000; it had, therefore, only been necessary to withdraw £4,300 from the reserve account in order to maintain the ordinary annual distribution of £245,000. An additional £39,750 had been provided from the Wells legacies for schemes of extension and other special purposes, bringing the total amount derived from this source to £284,750. During the thirty years since the institution of the King's Fund in 1897 a total of over five and a half million pounds had been distributed. The Earl of Donoughmore, chairman of the management committee, in moving the adoption of the report of the General Council for 1926, said that the total receipts of the King's Fund for the year were £285,749. The League of Mercy and the British Charities Association had each contributed £15,000. The amount spent on administration was £10,440, the equivalent of about 8½d. in the £ on the total received. The revised uniform system of hospital accounts had come into operation and was now obligatory on all hospitals receiving grants from the three central funds. The new scheme for the provision of pensions for hospital officers and nurses had been adopted by eighty-nine hospitals in London, representing 11,639 beds, out of a total of about 14,500. Sir George Lawson Johnston, chairman of the revenue committee, presented the report of the propaganda committee, and stated that more than one hundred cinema managers in and around London had expressed their willingness to exhibit during 1927 the hospital film entitled "A hundred years of progress." In addition to propaganda on behalf of the King's Fund and the hospitals, various new schemes for obtaining money had been inaugurated. The Prince of Wales read a message of congratulation from the King on the success of the Fund during 1926, and dwelt on the importance of obtaining new money for hospital extension now that the Wells legacies and the funds received for this purpose from the joint committee of the British Red Cross Society and the Order of St. John of Jerusalem were almost exhausted. In view of the valuable results which had already been obtained he appealed for generous donations to meet the new requirements, which were already known. He added that he had appointed a special committee to report upon the question of hospital accommodation in London for paying patients; the chairman would be Lord Hambleden, and the committee would include two medical members, Sir John Rose Bradford, P.R.C.P., and Mr. Warren Low, and two lay members, Sir Bernard Mallet and Professor Winifred Cullis, D.Sc. The Prince referred to the retirement from the council of Sir William Church, who had joined the Fund in 1899, and from 1903 to 1918 had been chairman of the distribution committee, succeeding the first chairman, Lord Lister, who was an original member of the council.

LEICESTER MEDICAL SOCIETY POST-GRADUATE LECTURES.

A course of five post-graduate lectures on the bearing of recent physiological discoveries on clinical practice was given at the Royal Infirmary, Leicester, during April and May, by Professor R. J. S. McDowall, at the invitation of the Leicester Medical Society, in conjunction with Leicester University College. The subjects treated were digestion, with special reference to gastric disease; surgical shock and its prevention; the rate of the heart beat and its significance in disease; high blood pressure in health and disease; and breathlessness. This course—the eighth of the kind—was unusual in that the lectures were given by a physiologist and not by a clinician, as in previous years. The experiment proved very successful, each lecture being attended by over fifty medical practitioners.

CENTRAL MIDWIVES BOARD.

The Central Midwives Board for England and Wales held a penal session and an ordinary meeting on May 5th.

The Board considered two letters from the county medical officer of health for Durham. To the one it replied as follows:

1. That under Rule F.1 it is the duty of a local supervising authority to suspend a midwife from practice whenever suspension is necessary for the purpose of preventing the spread of infection, and that whenever a midwife is suspended under Rule F.1 the provisions of Rule F.2 apply.
2. That the local supervising authority's duty is to prescribe the mode of disinfection (probably by a standing order), and to satisfy itself that adequate disinfection has been carried out before the midwife is allowed to return to work.

That no real delay need take place if proper arrangements are made.

In reply to the other it stated that the local supervising authority is at liberty to add any appendix to the approved form of keeping ante-natal notes, but that the Board's form must be kept intact.

A letter was read from the Ministry of Health as to the Board's resolution with regard to the scale of fees prescribed by the Minister under Section 14 of the Midwives Act, 1918; it drew attention to the correspondence and interviews which took place between the Minister and the Board when the revised scale of fees was under consideration. The Minister did not think it practicable to consider any alteration of the scale of fees in the manner suggested by the Board unless the Board was prepared to define the conditions to be regarded as emergencies for the purpose of Section 14 of the Midwives Act, 1918. Hitherto no case had been brought to the notice of the Minister in which a local supervising authority had received a claim from a doctor in respect of attendance after the expiration of four weeks from the date of confinement. The Board decided to take no further action.

Scotland.

GLASGOW POST-GRADUATE MEDICAL COURSES.

DURING the summer and autumn months various clinical courses will be held under the auspices of the Glasgow Post-Graduate Medical Association. Beginning on August 15th, a whole-time general medical and surgical course will be conducted for a month; the mornings will be devoted to general medicine, surgical diagnosis, and minor surgery in the Western Infirmary and Royal Infirmary, while each afternoon various subjects will be dealt with in the special hospitals of the city. On the four Saturday mornings there will be demonstrations on tuberculosis and the infectious fevers at Ruchill Fever Hospital. A morning course in clinical surgery will be arranged at the Royal Infirmary during June and July. The Western Infirmary will hold classes during the same two months in clinical gynaecology and dermatology, and courses, each lasting a month, will commence on September 13th in radiology, diseases of the throat and nose, and venereal diseases. From July to October classes for the study of the medical and surgical diseases of children will be arranged at the Royal Hospital for Sick Children. Beginning on September 12th, a month's course in clinical obstetrics will be held at the Royal Maternity Hospital, and a course in clinical gynaecology at the Royal Samaritan Hospital for Women. A series of demonstrations on diseases of the throat, nose, and ear will be conducted at the Ear, Nose, and Throat Hospital for a month, commencing on September 13th, if at least eight graduates enrol. Clinical assistantships are available at the Royal Infirmary, Western Infirmary, Royal Hospital for Sick Children, the Royal Mental Hospital, Glasgow Eye Infirmary, the Royal Maternity and Women's Hospital, the Royal Samaritan Hospital for Women, and the Ear, Nose, and Throat Hospital. Further information may be obtained from the secretary of the Post-Graduate Medical Association, the University, Glasgow.

Health Enterprise in Aberdeen.

The annual report on the City of Aberdeen for 1925, by Dr. J. P. Kinloch, medical officer of health, records investigations made by officers of the public health department into the immunology of scarlet fever and diphtheria, and describes how the data so ascertained are being turned to practical uses. With regard to scarlet fever, haemolytic streptococci were obtained from the throats of almost all cases during the initial stages, and the view is expressed that the same type of streptococcus may, according to circumstances, originate scarlet fever, tonsillitis, erysipelas, puerperal fever, or bronchopneumonia. Among children submitted to the Dick test in the age period 0-5 years, 95 per cent. gave a positive reaction. Among children of school age the positive rate was 78 per cent. in the west end of the city and 29 per cent. in the east. The active immunization of the staff of the City Fever Hospital reduced the incidence of scarlet fever among nurses to zero, as contrasted with a previous annual case rate of 9.5 per cent., an event which Dr. Kinloch justly claims, in the meantime, as very encouraging. Coincidently, however, with the disappearance of scarlet fever, streptococcal tonsillitis has increased among the nurses. *Naturam expellas furca, tamen usque recurret*, apparently even in Aberdeen! In order to prevent return cases of scarlet fever the remaining susceptible children in households have been immunized with good results. In testing the toxin employed for these purposes it was observed that the whole syndrome of scarlet fever, including inflammation of the fauces, the condition of the tongue, the punctate erythema, and the subsequent desquamation, may be called up by injection of the toxin alone. This result cannot be ascribed to the presence of a live filter-passing virus since it ensues equally after the filtrate has been heated to 55° C. for one hour. The task of preparing a scarlet fever toxoid for use in lieu of the toxin is at present engaging attention. As regards diphtheria, the active immunization of the City Hospital nursing staff has reduced the annual case rate from 11 to 1.6 per cent. Active immunization is not applicable in diphtheria, as in scarlet fever, to the prevention of return cases, since immunity takes about six months to develop: passive immunization is advised instead. The concurrent active immunization of children in the city against both scarlet fever and diphtheria by means of a combined prophylactic is being carried out on a community basis. This is a pioneer enterprise. The administrative and other procedures involved are set forth in the report, which treats, in addition, of the photometry of therapeutic lamps, the sunlight and lamp treatment of pulmonary and extrapulmonary tuberculosis, the causation of rickets, an outbreak of milk-borne Gaertner enteritis, the occurrence of paratyphoid and Aertrycke enteritis, and Sonne dysentery. Reference is made also to the progress of the new waterworks under the Aberdeen Water Act of 1916. Owing to interference with the existing city supply, described as inevitable in course of construction, the bacterial quality of the water distributed to consumers was in 1925 definitely below the standards of the two previous years.

Glasgow University Arrangements.

At a meeting of the University Court of Glasgow University on May 12th it was announced that Professor Harvey Cushing of Harvard University, Boston, U.S.A., would deliver the first Macewen memorial lecture in Glasgow University on June 21st, when the honorary degree of LL.D. would at the same time be conferred upon him. Permission was given to transfer five glass flasks, that had been used by Lord Lister in some of his experiments, from the physiological department, where they have been preserved, to the permanent keeping of the Hunterian Museum, Glasgow. Several gifts were also intimated. Lord and Lady Maclay had announced their intention to present an organ for the University Chapel at a cost of between £5,000 and £6,000. The late Mr. J. Murray Smith had directed his trustees to convey his house at 11, Bute Gardens, Hillhead, to the University of Glasgow, to be used as a professorial residence. Both these gifts were gratefully accepted. The Court, in a report on the Hunterian Museum for the year 1925-26 stated that the new museum building for the zoological collection was proving admirably suited to its purpose. An important cabinet of British molluscs collected during many years from the west coast of Scotland, had been presented by Dr. Frank Knight. The collection in the geological section had been considerably augmented by donations, and in the archaeological section purchases had been made of a complete collection of casts of the skulls of Paleolithic man. Additions had also been made to the collection of coins, some of which were of great rarity.

Postural Apnœa.

At a meeting of the Royal Society of Edinburgh on May 9th, Professor D. Noel Paton read a paper upon "Submergence and postural apnœa in the swan." It had, he said, been shown in 1922 that in the duck the stoppage of breathing that took place when the bird was feeding under water was not dependent upon the higher brain, but was a simple reflex action that could be brought about without immersion by putting the duck into the tail-up position; it was induced partly by the position of the head and partly by the extension of the neck. By a series of experiments upon the uninjured swan it had been shown that the stoppage of breathing was largely due to posture, and that both the position of the head and the extension of the neck were responsible for this, for by putting the swan in the feeding position out of water stoppage of breathing was produced.

Scotland's Position in Public Health.

An address was delivered, on May 3rd, by Colonel P. S. Lelean, professor of public health in the University of Edinburgh, to the Edinburgh Women Citizen's Association in the Usher Institute of Public Health. Professor Lelean referred to the importance of nutrition in building up the national health, and quoted figures to show that the general state of public health in England was more satisfactory than that in Scotland. The death rate in the former country was 12.2 as against 17 in Scotland, and the rejections of recruits for the army were in the proportion of 36 per cent. as against 43 per cent. Evidence also came from the United States, where the Englishman was placed at the head of the list of satisfactory immigrants, while the Scotsman was fifth or sixth, and came below the German. He next discussed the ill effects upon later generations of the mating of the half-witted, and went so far as to say that if this were allowed to proceed at its present rate the healthy mental stock of to-day would be swamped out in about four generations. What was specially needed at the present day was concentration upon the welfare of the children. This generation ought to live healthy lives itself, and its mothers should know how to bring up their children. Among the thirty-seven subjects which could be learned on request at secondary schools, health was not even mentioned. No particular instruction was given in schools regarding cookery, and yet unless decent cooking could be got into the homes of the working classes, and unless women could be taught how to buy to the best advantage the foods that were available, there would be no radical improvement in the C3 generation of our time.

Annual Meeting of the British Association.

A meeting of representatives of public bodies and scientific societies of Glasgow was held in the City Chambers, Glasgow, on May 10th, to make preliminary arrangements for the meeting of the British Association for the Advancement of Science, which is to be held in Glasgow in September, 1928. Lord Provost Mason presided, and various committees and office bearers were appointed. It was mentioned that the average attendance at meetings of the association held in Scotland was greater than the average in any part of England or elsewhere, and that this larger attendance indicated a greater interest in scientific matters, so that the association was living up to one of its principal objects of being "the mouthpiece of science to the public."

EXAMINATION OF MIDWIVES.

At the recent examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Aberdeen, and Dundee, out of 118 candidates 106 passed. Of the successful candidates, 24 were trained at the Royal Maternity Hospital, Edinburgh, 44 at the Royal Maternity Hospital, Glasgow, 4 at the Maternity Hospital, Aberdeen, 7 at the Maternity Hospital, Dundee, 8 at the Queen Victoria Jubilee Institute, Edinburgh, and the remainder at various recognized institutions.

EXPENDITURE ON SCOTTISH UNIVERSITIES.

The University Grants Committee in its report for 1925-26 gives statistics relating to the universities of Edinburgh, Aberdeen, Glasgow, and St. Andrews (including Dundee University College), and the Glasgow Royal Technical College. The items of income are as follows: endowments, £132,082; donations and subscriptions, £12,798; grants from local authorities, £40,179; parliamentary grants from the Treasury, £264,500, and from other Government departments, £19,919; class fees, £194,303; examination fees, £64,844; other income, £3,090; making a total income of £739,375. The items of expenditure are as follows: administration, £55,449; salaries and departmental maintenance, £433,230; laboratory maintenance, £60,841; library maintenance, £33,690; maintenance of premises, £97,981; and other expenditure, £58,790; making a total expenditure of £739,981.

Ireland.

MEDICAL REGISTRATION IN THE FREE STATE.

THE Medical Practitioners Bill, referred to in some detail last week (p. 896) has passed through all its stages in the Dail. An amendment moved by Sir James Craig, T.D. (Dublin University), that the Royal College of Surgeons in Ireland and the Royal College of Physicians of Ireland should each have one member on the Medical Registration Council, was accepted by Mr. McGilligan, the Minister in charge of the bill. In the bill, as introduced, the Royal Colleges were allotted only one member, who was to be nominated jointly by these bodies. An amendment by Dr. Hennessy, T.D. (Dublin City), providing that in the event of a casual vacancy occurring in the membership of the council of a direct representative, it should be filled by the resident medical practitioners in the Free State instead of the council co-opting a member to fill the vacancy, was also accepted by the Minister. With the exception of these two amendments, and another increasing the nominations of the Executive Council to two, the bill was passed substantially as introduced and as an agreed measure.

THE DENTISTS BILL.

The Dentists Bill, which has passed its first reading, follows closely on the lines of the British Act of 1921. There is, however, for the Irish Free State, a Dental Board of nine members, elected for four years, composed as follows:

(*a*) One nominated by the Executive Council.
(*b*) Three by the Medical Council.
(*c*) One by persons registered under Section 3, Dentists Act, 1921.
(*d*) Four by persons other than those registered under the latter section.

There shall be registered:

(*a*) Persons registered before the passing of this Act and resident in the Saorstat.
(*b*) Persons registered and living outside the Saorstat who apply for registration.

After the passing of the Act:

(*a*) Persons possessing a degree or licence conferred with authority.

The Saorstat Board is to have the same disciplinary control over dentists as the Medical Council will have over medical practitioners, and it will be exercised in the same way. It is proposed to give legal effect to an agreement signed on behalf of the Saorstat, Great Britain, and Northern Ireland. Under it the appointments made heretofore by the Lord Lieutenant for all Ireland will only apply to Northern Ireland, but the tenure of office of any member of the existing Board will not be affected. The Board may, by special direction on account of special circumstances, register any person who, in the opinion of the Board, has received training and possesses qualifications not inferior to the standard of training and qualifications necessary for obtaining the right to be registered. This section, it is understood, is intended to deal with cases in which there might have been a conscientious objection to go on the British *Register* in 1921, and to meet the case of a person who may have been serving with the volunteers in Ireland. Non-registered persons practising dentistry after the passing of this Act will render themselves liable to prosecution, and, if convicted, to a minimum fine of £50. Under the bill reciprocity with Great Britain and Northern Ireland will operate as in the case of the Medical Bill. The *Register* of 1921 would not be reopened, and any unqualified man who began to practise dentistry here since 1921 could not be registered, and would, therefore, unless he became qualified, have to discontinue. It would also eliminate for the future unqualified men.

India.

KASHMIR HOSPITALS.

DURING 1926 the work of the Kashmir Hospital of the Church Missionary Society continued to increase, the out-patients exceeding those of the previous year by over 4,000, while 1,983 were admitted as in-patients. In his annual report Dr. E. F. Neve, the medical superintendent, states that 1,104 operations were performed under local anaesthesia, and that a general anaesthetic was administered on 1,879 occasions. In Kashmir chloroform, given by the open method, is found very satisfactory, struggling in the second stage being almost unknown, except in the case of patients who have been in the habit of taking alcohol or Indian hemp. The staple antiseptic used is hypochlorite solution, prepared electrolytically in the hospital. Cancer is rare in Kashmir, but may, it is thought, be increasing. There were forty-eight cases of kangri-burn cancer, and Dr. Neve finds it difficult to reconcile the results of the investigations of Gye and Barnard with his clinical experience in Kashmir. Major eye operations numbered 310, and of the minor kinds 477 operations were performed for entropion and trichiasis, and 117 for cataract with no panophthalmitis or complete failure. Tuberculous and osteomyelitic bone disease was common, but appendicitis was rare. Enlargement of the prostate was almost unknown among Hindus, and uncommon in Mohammedans. Digestive disorders were increasing, owing to the excessive consumption of rice. The Kashmir State Leper Hospital, of which Dr. Neve is also honorary superintendent, dealt with 229 patients during 1926, of whom 179 were males. The prevalence of eye complications proved a serious obstacle to successful treatment, the most serious affection being the sclero-corneal tubercle, which advances across the anterior chamber, infiltrating the iris, and causing occlusion of the pupil. Dr. Neve adds that, though in more than thirty years in this hospital there has been no case of communication of leprosy from a patient to any of the staff, or from husband to wife, yet the children of leper patients manifest a diminished tissue resistance which seems to make them more prone to contract the disease.

GOVERNMENT OPHTHALMIC HOSPITAL, MADRAS.

In his report for 1926 Lieut.-Colonel R. E. Wright, I.M.S., superintendent of the Government Ophthalmic Hospital, Madras, states that there has been an increase in the total number of cataract operations performed at the hospital. The iris prolapse rate was rather over 8 per cent., but the vitreous escape rate in straightforward cases remained about the previous level—namely, 1.46 per cent. Late formation of the anterior chamber was another troublesome post-operative complication, and occurred in nearly 3 per cent. of the cases, including those where the chamber at first formed subsequently emptied. Better dilatation

of the pupil was secured by the use of adrenaline along with atropine prior to operation. Preliminary iridectomy was employed in a large number of cases, in order to minimize the risk of operating on eyes predisposed to glaucoma and other complications. Blocking of the facial nerve at the stylo-mastoid foramen was a routine procedure in the preparation of difficult patients for cataract extraction, and intraorbital anaesthesia with novocain and adrenaline was used in the case of painful eyes before iridectomy or other operations for glaucoma. Colonel Wright believes that it is very disadvantageous to leave blood in the anterior chamber, since fibrin appears to form a scaffolding for the building up of cellular elements. The danger of introducing organisms into the anterior chamber at the time of operation was demonstrated by special bacteriological investigations. In over 45 per cent. of the cases the field of operation harboured organisms, the majority of which were staphylococci. A Gram-negative coccobacillus was found in cultures from the iris, but it was not detected in the conjunctival field. In the out-patient department the chief affections dealt with were catarrhal conjunctivitis, inflammation due to the Koch-Weeks bacillus, trachoma, and phlyctenular and angular conjunctivitis. During the year training was given at the hospital to 187 medical students, 28 post-graduates, and 5 members of the Madras Medical Service, who attended for special tuition. A special certificate in ophthalmology is given to post-graduates who undergo nine months' training at the hospital and satisfy the examiners of their proficiency.

SIR NORMAN WALKER'S VISIT TO DELHI.

The Delhi Medical Association entertained at dinner, on February 17th, Sir Norman Walker, who was visiting that city in the course of his tour in India as a representative of the General Medical Council. Before the dinner Sir Norman Walker delivered an address in which he dealt at length with the etiology and treatment of various forms of skin irritation and pruritus. He also described the functions and powers of the General Medical Council, with special reference to its relation with universities. A short discussion followed on the question of the establishment of an Indian Medical Council.

THE PASTEUR INSTITUTE, CALCUTTA.

The Pasteur Institute in Calcutta was opened in 1924, and during the seven months of its active work in that year 1,995 patients were dealt with. The annual report of the institute for 1925 has now been received, and the superintendent, Lieutenant E. C. R. Fox, I.M.S., states that 5,585 patients attended, a considerable number having come from the province of Bihar and Orissa, as well as from Bengal. The number of patients who completed a course of prophylactic treatment for rabies was 4,168; of these 247 were Europeans and Anglo-Indians, and 3,921 Indians, 33 of whom developed hydrophobia. In 17 of these 33 cases symptoms of hydrophobia supervened more than fifteen days after completion of the prophylactic treatment, and must be considered failures. In the remaining 16 cases the disease developed before the treatment could be considered effective, and so are not included in the failure rate, which was 0.41 per cent., as compared with 0.48 per cent. in the previous year. More than half the Europeans who were dealt with had not been bitten, but only licked by the rabid animals, whereas 98.8 per cent. of the Indians had been bitten; similarly only 17 per cent. of the Europeans had deep bites, as compared with 46 per cent. of the Indians. While 82 per cent. of Europeans arrived within the first week of possible infection only 63 per cent. Indians received such early treatment; no treated European died of hydrophobia. In 26 per cent. of the total cases jackals were the rabid animals, the hydrophobia rate from them being 1.5 per cent., as compared with 0.6 per cent. for dogs; no Europeans, but 33 per cent. of the Indians, were bitten by jackals. During 1925 the work of the institute was carried on under difficulties in one room of the School of Tropical Medicine. An increase in the staff has been under consideration, as the institute has passed from the experimental stage, and its value is appreciated by all classes of the population.

Correspondence.

RHEUMATIC INFECTION IN CHILD

SIR,—The several letters which have appea issues of May 7th and 14th on the work of Committee's Subcommittee on Rheumatic Hear Children appear to need some comment from c the mind of the subcommittee.

Professor Leonard Findlay stands, I thi honoured position of having been the first in G to open a special hospital department for the t rheumatic children. Not unnaturally he disagr subcommittee's conclusion that it is a mistake routine treatment in such special clinics, and t all cardio-rheumatic cases entirely separate general work of the hospital. I can assur Findlay that the Glasgow plan was most ca sidered by the subcommittee, but that a sch taking supervision only and referring all treat appropriate departments of the hospital was better and more immediately practicable. For t there were several reasons. (1) The plan o treatment clinic would not be generally accept staffs of voluntary hospitals, especially thos pediatrics. Already such teachers have lost clinics infectious diseases, and no small pr cases of tuberculosis, venereal diseases, and fe culties: the subcommittee had no desire to a submit to the loss of rheumatic and cardiac (2) Were such a scheme accepted by the voluntar it would be to the disadvantage of ordinary st thus ultimately of the rheumatic child. (3) V accepted by them, and yet were held up b committee as the ideal procedure, there m tendency for such clinics to be set up in assoc dispensaries, welfare and minor ailment centres places all divorced from the facilities of a l seeing a child through every phase of its illnes of course, the very plan the subcommittee deprecate. I will only add that in a supervi from which patients can be admitted direct to referred to special departments or back to physicians, emergency treatment being given in time, the patients lack nothing; and there is Professor Findlay to be "inclined to consider futile."

The subcommittee did not consider such mat classification of cases attending rheumatism which Dr. Margaret Lowenfeld lays such stress difficult to agree with her view on this point never felt much enthusiasm personally for the c adopted by her, either in principle or in detail I am afraid I must leave the matter.

For Dr. Halls Dally to state that the signific "quiescent stage" in juvenile rheumatism was nized until May, 1926, gives me such a shock a me from disputing the point with him.

The letters of Dr. L. Thorne Thorne and McCall, who "differs" from him, raise the question of the influence of compulsory school on the production of rheumatism. Taking prov I venture to agree with both disputants. The not an easy one, but it seems clear that expos weather in going to and from school cannot l of great importance in originating the disease i as the disease is much more common in indust where distances are short, than in rural areas, are longer. Yet there cannot be the slightest such exposure is bad for rheumatic children, increase the severity of the infection and thus heart disease. It is the old difficulty of wl produce, and what merely unmask and incr matism. It was along these lines that the su thought the truth of the matter would be reach

Dr. J. S. Pearse, under the title of "Damp (May 14th), asks for details of how the figure houses were collected for the subcommittee's f The housing of rheumatic children was examined

Bristol, Bath, and Birmingham by different investigators, all using, however, the same questionary. In nearly all cases the houses were visited: in some places by the medical officers, in others by sanitary inspectors, health visitors, or lay workers. The questions asked are given in the first report, and, roughly speaking, it was our endeavour to count as damp such houses as would appear damp to an intelligent layman rather than to abide entirely by the decision of the responsible sanitary inspector. Further experience of such investigations has taught me that, if the right questions are asked in the right manner, there is little difficulty in getting the truth from the inhabitants. Recent figures collected at the Supervisory Centre at Paddington Green Children's Hospital, where parents are questioned and afterwards visited, show a very small percentage of error, well under 5 per cent. I do not think that architects would approve of Dr. Pearse's view of the lack of significance in the presence of condensation-damp in a house, for, as I understand it, they regard this as a bad fault; and surely where such damp is persistent this view is not unreasonable. I know of no definite figures showing that the rheumatic diathesis is "inimical to tuberculosis," though such a view has often been expressed and is largely accepted.—I am, etc.,

London, W.1, May 14th. REGINALD MILLER.

SIR,—As an assistant school medical officer of some years' experience I cannot agree with Dr. Eva McCall's criticism (May 14th, p. 898) of Dr. Leslie Thorne Thorne's view that the present system of school attendance may be a factor in the production of rheumatic infection in children.

At school the child suffering with a slight chill cited by her is quite commonly sitting at a desk with damp feet in an inadequately warmed and ventilated room—a danger to himself and a source of infection to his classmates. But, however wretched the home, it is indeed rare that there is no fire at which he can warm and dry himself, no hearthrug on which he can rest his aching limbs, and no relative or neighbour at hand with resource enough to give him a warm drink.

In the majority of elementary schools I have visited there is no provision for drying the feet, and I have often found wet coats piled promiscuously together in the cloakroom.

For these reasons, when discussing the wet shoes of infants arriving in school through a snow thaw, I have advised their dismissal, but only secured that the obviously wet through were sent home.

Change of footwear, drying rooms for clothes, and a sick-room should be regarded as necessities in schools under the present system of compulsory attendance. Moreover, the substitution for attendance officers of nurses instructed to investigate a temporary ailment rather than to demand a medical certificate would, in my opinion, prevent many a catastrophic illness and promote the peace of mind of harassed parents "afraid of a summons."—I am, etc.,

MARION BURT, M.B., B.S., D.P.H.

Birmingham, May 14th.

SIR,—Much has been, and is being, done in regard to the prevention and treatment of rheumatic infection in children. There is one matter, however, which, I hope, will not be overlooked, or its gravity underestimated—namely, the part played by defective drainage and infected reflux air; this especially when damp ground-floor dwellings are suspect.

B. coli communis and streptococci are commonly present in sewer air, and puerperal fever—a pure septicaemia—has, in many instances, been traced to faulty drains. Inhalation of such air can seriously affect health. Headache, sickness, sore throat, and anaemia are results well known to occur from poisoning by the inhalation and adsorption of infected emanations from drains.

No drainage system can be perfect. Traps, joints, and ventilators are easily liable to go wrong; they may leak and become readily forced by sewer gas, yet nobody dares think of investigating the efficiency of his house-drains until they compel him to.

For long it has been my custom in cases of sore throat of any kind, whether in child or adult, to advise the weekly cleansing of all house-drains by flushing with chlorinated lime in hot water. There is no cheaper or better deodorant and disinfectant for the purpose. The lime and hot water are simply run down each drain at night once a week, and left in the drains all night, then run off in the morning. I am quite convinced of the value of such an attempt at disinfection, and of its real necessity in the prevention of sore throat and rheumatism in children.—I am, etc.,

Bournemouth, May 14th. S. WATSON SMITH.

THE CONSTITUTIONAL FACTOR IN DISEASE.
